Figure D.919: Edmund Tilley. October 1946. Report on the interrogation of Edmund Sorg. [TNA FO 1031/57] “Specially adapted models of V-1 manned by pilots prepared to sacrifice their lives were to receive a powerful charge with which to destroy key targets, such as vital war plants and large battleships... It is more likely that the charge for the warhead which had been envisaged was not available in sufficient quantities. Significantly SORG mentioned an atomic charge for these suicide V-1s as the ideal explosive in a future ‘defensive’ war.”

Hans Kammler. 23 April 1945 telegram. [BA (Bundesarchiv). Bestand NS 3/514, pp. 31–32. Microfilmed as: NARA RG 242, Records of the Reich Leader of the Schutzstaffel (SS) and Chief of the German Police, Microfilm 183, NAID 273992206 (https://catalog.archives.gov/id/273992206)].

Geräte V 1 bei Berlin sofort sprengen.	Immediately blow up V 1 devices near Berlin.

[See document photo on p. 4901.

This was one of the last known communications Hans Kammler sent before he (secretly) surrendered to U.S. forces (pp. 4931–4959). "V 1" probably meant V-1 cruise missiles, although it is possible that it referred to some other type of device. V-1 cruise missiles had been mass-produced and were widely available, so there must have been something especially noteworthy about these particular V-1s. "Blow up" (sprengen) seems to have meant to destroy them before they could be captured, not to detonate them by firing them at targets, since no targets were mentioned.

The most likely explanation is that these were V-1s that had been modified to carry nuclear, chemical, or biological weapons, and that Kammler wanted those advanced weapons/evidence destroyed before Russian forces captured Berlin. Note that there were more than one of them (Geräte is plural). This document complements the evidence cited above that specially modified V-1s were constructed during the war and intended for strategic Allied targets before the end of the war.]

Edmund Tilley. Brief Operational Report on [censored] and Other Germans and Italians Connected with Project Abstract. 19 August 1947. [NARA RG 319, Entry A1-134A, Box 29, Folder Operation Oberjoch]

1. On 11 August 1947 [censored] on the Italian phase of PROJECT ABSTRACT, which, in a few previous reports, was called Operation Arrival or Arrivederci, [censored] Headquarters, USAFE, by Captain R.R. SNEIDER of the CIC Detachment, BAD KISSINGEN. Major A J. LEOCHA [censored]

2. [Censored]

SANITIZED COPY
SENSITIVE INFORMATION DELETED

[...] New Facts and Re-affirmation of Statements on PROJECT ABSTRACT.

4. Thorough cross-examination has not been effective in shaking [censored] on matters directly concerned with or related to PROJECT ABSTRACT.

a. Atomic research and development at TUCHELER HEIDE was coupled with research on guided missiles, in 1943 and 1944. (Note: In March 1947 Professor W. von BRAUN admitted that in the summer of 1943 he had been interested in atomic energy for use in V-2. Von BRAUN claimed to have dropped the project for lack of available raw materials. It may be mere coincidence that [censored] also places the beginning of combined research and development in 1943.—In March and April 1945 the undersigned heard rumors in Germany of such a combination. The most persistent rumors in I.G. FARBEN circles had it that this combination would be linked with Chemical Warfare, especially with the new nerve gases, i.e., the TABUN series. These rumors were repeated by responsible members of I.G. FARBEN, who added that this vague plan or hope had been abandoned. At the time no progress was made in the investigation of the atomic side of the problem because all effort was concentrated on a solution of the new Chemical Warfare problem. [Censored] now reveals that the ampullae (phials) he saw in four boxes in Italy had originated with I.G. FARBEN. (See b below).

b. Four boxes, probably originating in the Luftwaffe Ministry in Berlin, were sent in March 1945 by SD, POTSDAM, to ITALY in the care of a FELDWEBEL (Sergeant) HEINZ (surname forgotten!), [censored] and a Private (name forgotten!). The boxes contained (i) reports and research data on V-weapons and atomic research; (ii) 40–50 small ampullae (phials) "full of a whitish liquid", labeled U-234, U-235 and PLU, stamped "IG" (= IG Farbenindustrie); (iii) a new and not completely developed optical instrument probably intended for measuring speed and trajectory of guided missiles at the firing point; (iv) various small and delicate parts of guided missiles, fastened to cardboard by fine wires, with full description of each item attached to the cardboard.

c. The boxes were buried near VERONA by the FELDWEBEL, [censored] and a third soldier. (The site has been explored. Parts of wooden boxes or of a wooden box, fragments of paper and an ampullae (phial) marked U234 or U235 were seen by Captain SNEIDER and [censored]. The rest had vanished). [...]

BREE may be the same "person with a French name" (BOREU?) who worked spasmodically on "electric fuses for guided missiles" at TUCHELER HEIDE in 1943 and 1944. Thus he would know valuable details on the combined "guided missiles–atomic energy" research and development and would perhaps know where the missing documents were sent, whether they went first from TUCHELER HEIDE to BERLIN, as [censored] vaguely stated, and thence to SD, POTSDAM, and to Italy.

24. Ingenieur KRUEGER should be traced and brought at once to ECIC. He may give us valuable information on the combined "guided missiles–atomic energy" program at TUCHELER HEIDE in 1943 and 1944 and may know exactly where documents and instruments have been sent. [Censored] obtained most of his information on activities at TUCHELER HEIDE from KRUEGER, in 1944.

25. Prof. Dr. NIELS [Walter Nielsch?], now said to be in the United States, was, according to [censored,] concerned with chemical and atomic problems at TUCHELER HEIDE and produced a number of atomic bombs, weighing from 1 to 5 kilograms. NIELS should be traced and questioned in detail.

26. Prof. Dr. HUETTEN. Present whereabouts unknown to [censored.] He should be located and brought to ALASKA for questioning. According to [censored] he was the originator of the combined project of research and development of atomic energy and guided missiles at TUCHELER HEIDE. This project was named "Aktion HUETTEN" after him. He was transferred elsewhere, probably in 1943 (see paragraph 7).

27. Prof. Dr. HOFMANN, successor of HUETTEN as chief of the combined program at TUCHELER HEIDE, is now at "ALEXANDROWKA Kononien" near BAKU where he is continuing his former work. [...]

28. Prof W. Von BRAUN should be re-interrogated on the following: [...]

[For information on Edmund Tilley, see pp. 4894–4895. For more information on Project Abstract, see Mills and Johanson 2019.

The German military took over Tucheler Heide in September 1939 and used it as a proving ground (Truppenübungsplatz Westpreußen or Heidekraut) for rockets, nuclear work, and other experiments until January 1945. See p. 4462.

Walter Dornberger briefly mentioned rocket testing at Tucheler Heide [Dornberger 1958, pp. 227–229].

Dr. Walter Nielsch (German, 1915–20??) was an expert on chemical metallurgy [e.g., https://www.semanticscholar.org/author/W.-Nielsch/16969230] and a plausible candidate to have been involved in the purification of uranium-235, uranium-233, and/or plutonium-239. What exactly did Dr. Nielsch and/or Dr. Niels do during the war and also after the war?

Were the "number of atomic bombs, weighing from 1 to 5 kilograms" fission fuel pits for bombs?

Was this work on a nuclear-armed projectile at Tucheler Heide in Poland related to the alleged test of a nuclear-armed projectile in Poland (Section D.11)? See p. 2096 for a map of other known research sites in Poland.

The March 1947 interrogation of Wernher von Braun, mentioned in this document, is described in more detail in the document on p. 5762.]

Germ. Pers.

23 May 1945

Subject: Obergruppenführer Kaltenbrunner and Otto Skorzeny.

To : Major Francis J. Smith, Room 5119, New War Department Building, Washington, D. C.

1. This officer, accompanied by Mr. John Cimperman, FBI Representative, U. K., went to 12th Army Group Headquarters on 20 May 1945 for the purpose of interviewing Obergruppenführer Kaltenbrunner and his subordinate Lieutenant General Otto Skorzeny. As you know, Kaltenbrunner was head of the RSHA in Germany. The RSHA controlled all intelligence both domestic and foreign for Germany. Skorzeny is a subordinate of Kaltenbrunner and was head of AMT VIS, which is the sabotage section of the RSHA. He also controlled the special troops which the RSHA had attached to it.

2. Both Kaltenbrunner and Skorzeny had just arrived one day previous to our visit and in that period of time very little information had been elicited. It was thought that at least a week would be needed for the initial background investigation and it was agreed that it would not be feasible to intregate our questions in the interrogation for possibly another five or six days. It is estimated it will take that long to obtain tactical information from them, such as location of RSHA personnel and files.

3. In addition to Kaltenbrunner and Skorzeny there are also their personal adjutants, some members of their staff and their mistresses.

4. Kaltenbrunner is reported to be a man of extreme ability as a lawyer and also extremely cautious in answering all questions. While he is talking, he is saying nothing that will further incriminate himself and professes ignorance on many activities under his control and tries to elude direct answers by stating "that is in the jurisdiction of so and so".

5. Skorzeny on the other hand is a willing talker and very cooperative. He claims to be a professional soldier and wants to be treated in accordance.

6. The present status is that we left with the interrogators a set of very general questions dealing with intelligence activities in the Western Hemisphere. These questions are to be intregated into the initial interrogation and if anything of interest arises I will then go back for a more detailed interrogation.

For the Military Attache:

ANNEX NO III

Comments on Amt III

PRISONER: O/Gruf KALTENBRUNNER, Ernst DATE: 28 June 1945

K. explains that it had been his aim to change the role of the SD from a negative, and criticizing one to that of a positive, and constructive organization. In line with this policy was the interest of Amt III in technical advance, especially when it touched the war effort. OHNESORGE, the minister in charge of the Reich Postal Service had been directing the improvements of already existing equipment. He was supported by Amt III where SEIBERT and SPENGLER handled questions of technical developments. One of the inventions OHNESORGE's scientists had made was an infra-red light which enabled vehicles to move about during blackout. Another one concerned radar equipment.

The last report issued by Amt III dealt with the Luftwaffe. This report had been prepared by SEIBERT and SPENGLER. It was about 40 pages long, and was subdivided into three parts. The first dealt with the over organization of the Luftwaffe which had retained the number of different commands it had at the time of its greatest expansion, e.g. separate organizations for reinforcements, flak, supplies, etc. The report recommended that these organizations be broken down and that infantry units be formed from the surplus personnel. The second part of the report concerned technical matters. It criticized the mistaken use of the ME 262 as a bomber instead of a fighter. It pointed out that in many instances the Luftwaffe had continued to build obsolete aircraft types and it discussed in detail the Luftwaffe's armament reserves. The third part of the report contained proposals for improvements.

Before the report was shown to HITLER, K. removed the criticisms of GOERING. He felt that HITLER was already more than familiar with them. K. also took the report to GOERING who was grateful for being consulted and for the omissions.

The Luftwaffe report was based on information which had, for the larger part, come from sources outside the SD. K. explains in this connection that the attitude of the public towards the SD had undergone a decisive change in the last two years. While in the early part of the war nobody out-side of the SD would have thought of contacting Amt III to report criticisms of the government, lately a great number of people had felt that the SD was the only agency willing to listed. And since the state of the Luftwaffe was an open scandal, pilots, inventors, and production men, came to report their observations.

The report on the Luftwaffe was unique and normally Amt III did not touch matters concerning the German armed forces, so as not to encroach on Mil Amt which reported its findings directly to the Wehrmachts Fuehrungs Stabe.

c. Amt III and the Old Abwehr - 20 July 1944

K. insistes that Amt III had no agents in the Abwehr, in keeping with an unwritten law according to which the SD never spied on Wehrmacht personnel. K. admits that the Abwehr always suspected the SD of having planted agents among its personnel - a suspicion that the Abwehr thought was confirmed by the many arrests of its members after 20 Jul. K. counters this argument with the assertion that the SD had known for a long time that the personnel of the Abwehr was reactionary and "rotten", but it was unable to do anything about it. If the RSHA had been in a position to take action the Abwehr officials who figured prominently in the 20 July events would have been eliminated long before.

Interrogation Report No. 517.
Ref. No. AIU/PIR/135.
11th June, 1947.

BRITISH INTELLIGENCE OBJECTIVES SUB-COMMITTEE

Interrogation of Karl FIEBINGER
on 7th May, 1947

Target No. C22/6925

Main Interest: Building Construction.

1. PERSONAL HISTORY

a. Citizenship: Austrian.

b. Address: Salzburg, Kapellenweg,16, (presently under Salzburg town arrest).

c. Date and Place of Birth: 20 January 1913 at Vienna, Austria.

d. Description: Height 6'1"; weight 187 lbs; brown hair; blue eyes; married, no children.

e. Education: Attended Technische Hochschule, Vienna from 1931 to 1937, studying civil engineering.

f. Political Affiliations: NSDAP applicant since June 1938, member of NSV since 1941 and of NSBDT (Nazi Engineering Association) since 1939.

g. Military Service. None.

2. OCCUPATIONS: Upon completing his studies at the Technische Hochschule, Fiebinger accepted a position as assistant professor in the "Eisenbetonbau und Static" (Reinforced Concrete Construction and Statics) section of the civil engineering department of the Hochschule in September of 1937. His reputation grew so rapidly that Professor Dr. Ernst Melan, then chief of the Hochschule's civil engineering department, asked his co-operation on a huge construction project of a cement factory to be built at Kirchbichl Tyrol. This project was initiated in October of 1938 and was later known as "Perlmoser Cement Werke". It occupied Fiebinger so fully that he was unable to carry on with his duties as assistant professor at the Hochschule. On 15 April 1939, he established his own office in Vienna, which was known as "Buero fuer Bauwesen Dipl. Ing. Karl Fiebinger". He claims to have employed a staff of 40 engineers and to have gained national recognition for the many projects he handled between 1939 and the end of the war, a fact which was borne out by statements made to interrogators by his former associates. Fiebinger moved his office to Strobl on the Wolfgangsee, in February 1945. Upon cessation of hostilities, he claims to have presented detailed plans for underground installations constructed by him at Ebensee, (V-2); Melk (Ball Bearings); Redl Zipf (V-2), Messerschmitt [redacted]) at St. Georgen, to a team of American investigators that was alledgedly dispatched from Paris in June or July 1945 specifically for this purpose. During the fall of 1945 Fiebinger organized a new concern in Salzburg, called "Spezial Baugesellschaft, Salzburg" (Firm for specialized construction), which was contemplating the production of small wooden houses. His work wasinterrupted in February 1946 by his arrest by American authorities as a security threat. The reason for his arrest, as stated on his arrest report, is the supervision of important SS building matters, including a V-2 factory and a crematory for a concentration camp at Ebensee, for which slave labor was used and for which he allegedly received 1,000,000 marks. Fiebinger denies the above charges. On the 29th April, 1947, he was removed from the full arrest category and placed under town arrest in Salzburg, per letter order from G-2, United States Forces in Austria.

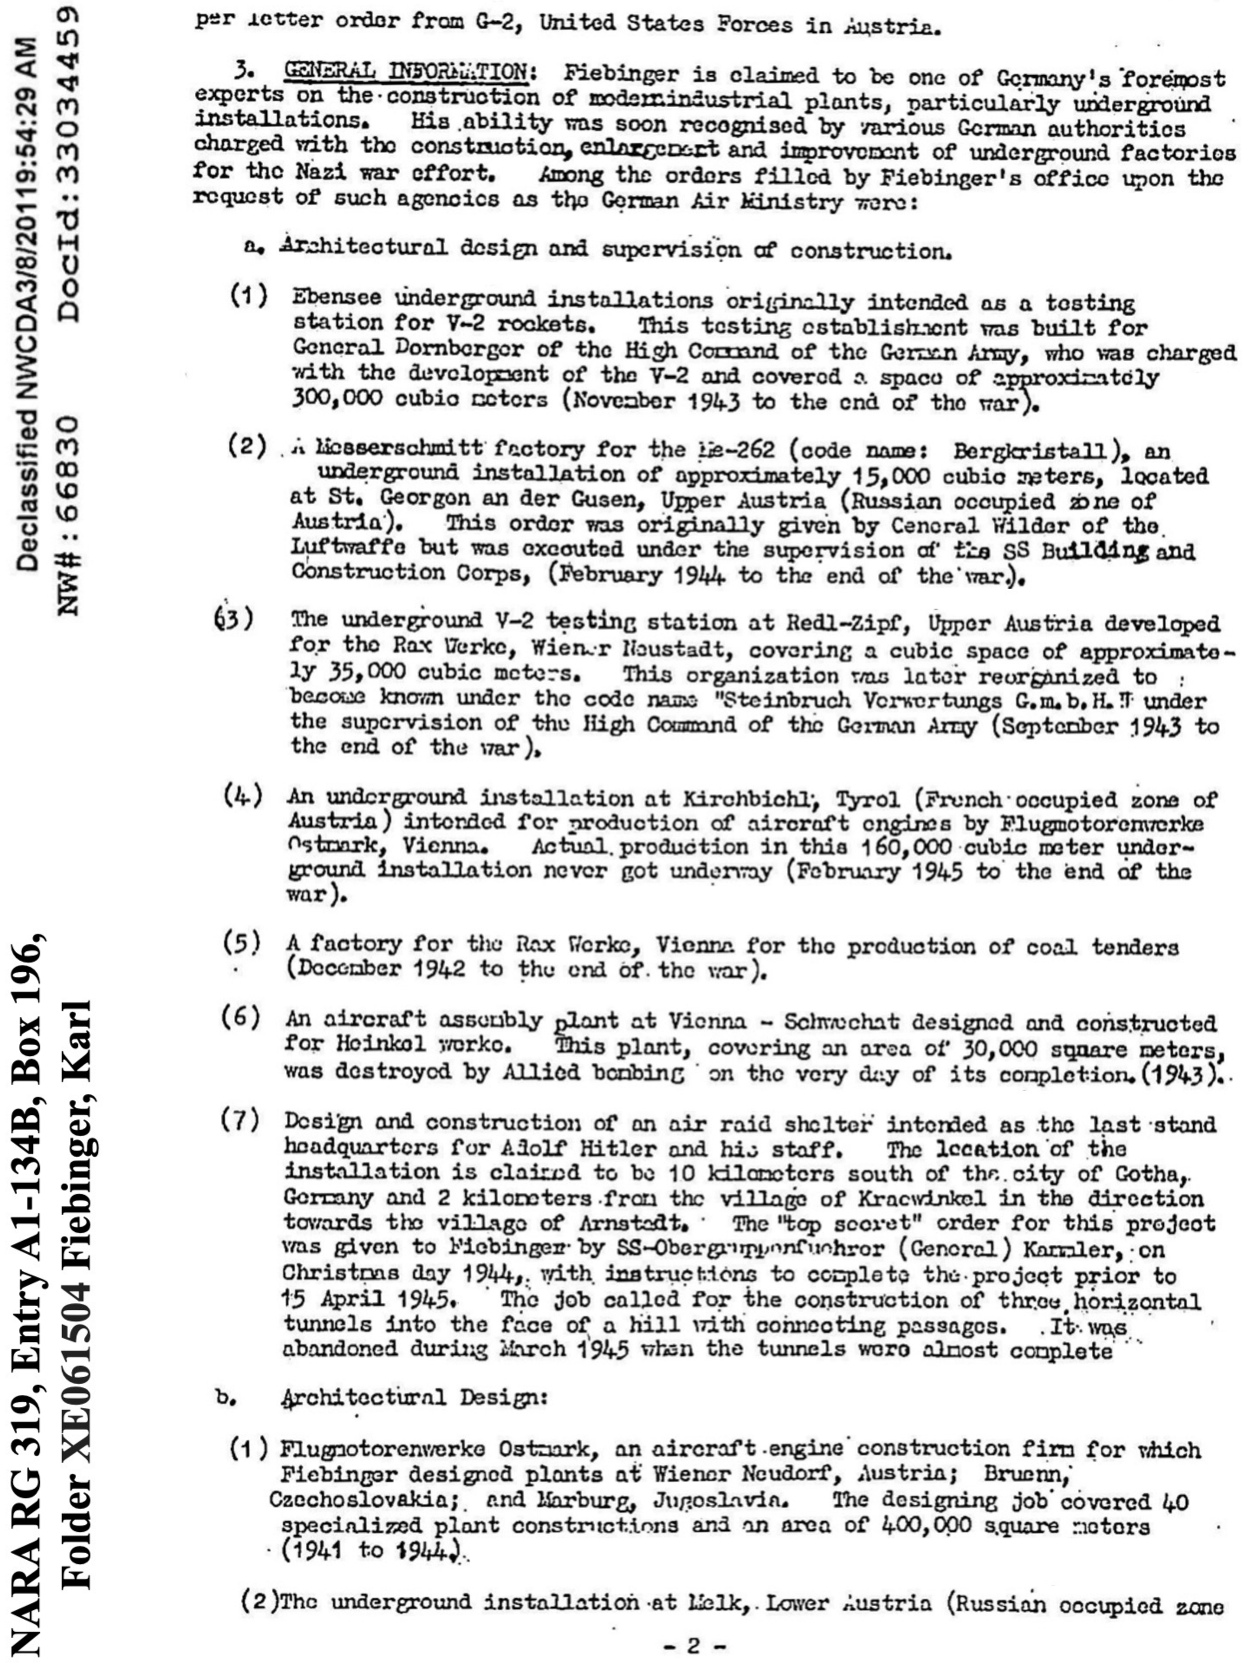
Figure D.924: Karl Fiebinger was the chief engineer of many massive underground facilities for advanced weapons production in the Third Reich. After the war he was interrogated by the U.K. and U.S. and worked for the United States. [NARA RG 319, Entry A1-134B, Box 196, Folder XE061504 Fiebinger, Karl]



Declassified NWCDA3/8/20119:54:29 AM DocId:33034459 NW#:66830

NARA RG 319, Entry A1-134B, Box 196, Folder XE061504 Fiebinger, Karl

per letter order from G-2, United States Forces in Austria.

3. GENERAL INFORMATION: Fiebinger is claimed to be one of Germany's foremost experts on the construction of modern industrial plants, particularly underground installations. His ability was soon recognised by various German authorities charged with the construction, enlargement and improvement of underground factories for the Nazi war effort. Among the orders filled by Fiebinger's office upon the request of such agencies as the German Air Ministry were:

a. Architectural design and supervision of construction.

(1) Ebensee underground installations originally intended as a testing station for V-2 rockets. This testing establishment was built for General Dornberger of the High Command of the German Army, who was charged with the development of the V-2 and covered a space of approximately 300,000 cubic meters (November 1943 to the end of the war).

(2) A Messerschmitt factory for the Me-262 (code name: Bergkristall), an underground installation of approximately 15,000 cubic meters, located at St. Georgen an der Gusen, Upper Austria (Russian occupied zone of Austria). This order was originally given by General Wilder of the Luftwaffe but was executed under the supervision of the SS Building and Construction Corps, (February 1944 to the end of the war).

(3) The underground V-2 testing station at Redl-Zipf, Upper Austria developed for the Rax Werke, Wiener Neustadt, covering a cubic space of approximately 35,000 cubic meters. This organization was later reorganized to become known under the code name "Steinbruch Verwertungs G.m.b.H." under the supervision of the High Command of the German Army (September 1943 to the end of the war).

(4) An underground installation at Kirchbichl, Tyrol (French occupied zone of Austria) intended for production of aircraft engines by Flugmotorenwerke Ostmark, Vienna. Actual production in this 160,000 cubic meter underground installation never got underway (February 1945 to the end of the war).

(5) A factory for the Rax Werke, Vienna for the production of coal tenders (December 1942 to the end of the war).

(6) An aircraft assembly plant at Vienna - Schwechat designed and constructed for Heinkel werke. This plant, covering an area of 30,000 square meters, was destroyed by Allied bombing on the very day of its completion. (1943).

(7) Design and construction of an air raid shelter intended as the last stand headquarters for Adolf Hitler and his staff. The location of the installation is claimed to be 10 kilometers south of the city of Gotha, Germany and 2 kilometers from the village of Kraewinkel in the direction towards the village of Arnstadt. The "top secret" order for this project was given to Fiebinger by SS-Obergruppenfuehrer (General) Kammler, on Christmas day 1944, with instructions to complete the project prior to 15 April 1945. The job called for the construction of three horizontal tunnels into the face of a hill with connecting passages. It was abandoned during March 1945 when the tunnels were almost complete

b. Architectural Design:

(1) Flugmotorenwerke Ostmark, an aircraft engine construction firm for which Fiebinger designed plants at Wiener Neudorf, Austria; Bruenn, Czechoslovakia; and Marburg, Jugoslavia. The designing job covered 40 specialized plant constructions and an area of 400,000 square meters (1941 to 1944).

(2) The underground installation at Melk, Lower Austria (Russian occupied zone

NARA RG 319, Entry A1-134B, Box 196, Folder XE061504 Fiebinger, Karl

of Austria), known under the code name "Quarz". This installation was constructed as a combination evacuation plant for the above mentioned firm "Flugmotorenwerke Ostmark" and the firm of "Steyr-Daimler-Puch", Steyr, Upper Austria. The scheduled production of ball bearings was never realized due to the course of the war. The Melk installation covered a cubic area of 120,000 cubic meters. The end of the war interrupted its completion. (February 1944 to the end of the war).

(3) A plant covering 40,000 square meters designed for Steyr-Daimler-Puch, producers of aircraft engines, at Steyr. Upper Austria (November 1941 to April 1943).

(4) Various designs for Junkers Werke, Dessau, i.e., a new aircraft engine factory at Prague (1942) and two construction plants at Bernburg and Aschersleben, both near Dessau, Germany (1942).

(5) Design of a factory intended for the production of 1000 bombers per month, scheduled to be built at Oels, near Breslau for the German Air Ministry. This project was later abandoned (1942 to 1943).

(6) Perlmoser Cement, a huge cement factory at Kirchbichl, Tyrol (French occupied zone of Austria), scheduled for a production of 100,000 tons of cement per year. Project was never completed. (1938 to 1940).

(7) Design of air raid shelters, bridges and river control systems for the city of Vienna. (1941 to 1943).

4. DISPOSITION: Fiebinger is being further interrogated on German construction methods of underground installations. Any headquarters requiring further information should forward a brief outlining specific information desired to Chief, Air Section, Headquarters, United States Forces in Austria.

b) Gefangennahme,

c) Registrierung meines Einganges in die britische Zone (festgesetzt auf den 14. 08. 1947—aber bereits in Lübeck—s. anliegende Abschrift des englischen Registrierscheines Nr. 001013 vom 1. 09. 1947, Intelligence Team Friedland Camp),

d) Entlassung aus der Gefangenschaft und

e) Zuzugsgenehmigung durch den Regierungspräsidenten Hildesheim (Bezirksflüchtlingsamt) von 9. 9. 1947 (s. Anlage zu 25 c)."

Als Wohnorte gab Schumann an: Göttingen 1947, Hamburg 1948, Düsseldorf 1953 und Detmold 1956.[1313]

Schumann's statement from January 1957 goes on to say:

"I stayed with friends between May 1945 and May 1947, mostly in Berlin. That's how I initially escaped capture or imprisonment. It was only in the spring of 1947 that I spoke to Mr. Geh. Rat. Prof. Dr. Planck (in Göttingen at the time) about my placement in the West. After making inquiries with the British authorities, he recommended that I report personally to the British in Göttingen. As a result, I registered with the British occupation authorities in Göttingen in July 1947 (handing over a deregistration form of that date from Dolgelin, where I did not personally deregister, but had myself deregistered. A good acquaintance gave me the deregistration certificate).

The British occupation authorities then arranged for

a) Interrogation (but still at large),

b) capture,

c) registration of my arrival in the British zone (for 14 August 1947—but already in Lübeck—see attached copy of British registration certificate No. 001013 dated 1 September 1947, Intelligence Team Friedland Camp),

d) release from captivity and

e) Relocation permit from the Hildesheim District President (District Refugee Office) dated 9 Sept. 1947 (see attachment to 25 c)."

Schumann gave his places of residence as: Göttingen 1947, Hamburg 1948, Düsseldorf 1953, and Detmold 1956.[1313]

Für die von Planck empfohlene Verbindungsaufnahme mit englischen Stellen in Göttingen nutzte Schumann seine frühere Bekanntschaft mit Telschow, der sich in Göttingen aufhielt—damals Sitz der aus Berlin ausgewichenen KWG. Am 4. August 1947 stellte Telschow den Kontakt Schumanns mit den Engländern her. Zwei Monate später übergab Schumann in Göttingen an "Herrn Porhase (AVA)" einen kurzen Bericht über das Reichweitengeschoss, der für einen Mister Groves bestimmt war. Dieser Vorgang belegt ein weiteres Mal die bekannte "Situations-Geschicklichkeit" (Cobarg) Schumanns. Vergleicht man nämlich den dürftigen Bericht (eine Schreibmaschinenseite!) mit den tatsächlichen Forschungsergebnissen zum Trommsdorff-Geschoss (vgl. Kapitel 12), dann weiß man sofort: Schumann hielt den Engländern einen kleinen Happen hin, den eigentlichen Braten behielt er für sich.[1314]

Was Schumann damals alles seinen "neuen englischen Freunden" von den Geheimnissen der deutschen Rüstungsforschung preisgab, lässt sich nur erahnen. Aber es muss—wie noch an anderer Stelle belegt wird—so ergiebig und wertvoll gewesen sein, dass die Engländer hin und wieder ihre schützende Hand über den Professor hielten. Solche Art Fürsorge hatte Schumann in den ersten Jahren nach dem Krieg mitunter auch bitter nötig, vor allem wegen einiger Prozesse, in denen seine Person eine Rolle spielte.

Schumann used his previous acquaintance with Telschow, who was in Göttingen–at that time the headquarters of the KWG, which had been evacuated from Berlin–to establish contact with the British authorities in Göttingen, as recommended by Planck. On August 4, 1947, Telschow established Schumann's contact with the British. Two months later, Schumann handed over a short report on the long-range projectile to "Mr. Porhase (AVA)" in Göttingen, which was intended for Mr. Groves. This process once again demonstrates Schumann's well-known "situational dexterity" (Cobarg). If one compares the meagre report (one typewritten page!) with the actual research results on the Trommsdorff projectile (cf. Chapter 12), then one knows immediately: Schumann held out a small morsel to the English, he kept the actual roast for himself.[1314]

We can only guess what Schumann revealed to his "new English friends" about the secrets of German armaments research. But it must have been—as is documented elsewhere—so productive and valuable that the English occasionally held their protective hand over the professor. Schumann was in dire need of this kind of care in the early years after the war, especially because of a number of [war-related] trials in which he played a role.

[1313] Schriftliche Erklärung Schumanns vom 5. January 1957 "Anlage zu 24c und 25a", NL Schumann. Die Grunde, die zu dieser Erklärung führten, sind nicht bekannt.

[1314] Briefwechsel Schumann/Telschow 1947/48, AMPG, III. Abt., Rep. 83, Nr. 286. Interessant ist, dass in dem kurzem Vermerk auf den Bericht "Reichweitengeschoss" hingewiesen wird, dieses Dokument jedoch im Nachlass Telschow nicht vorhanden ist. Eine Kopie befand sich im Nachlass Schumann, mit handschriftlichem Vermerk zum Termin der der Abgabe an "Porhase", bestimmt für den Empfänger Groves.

[1313] Written declaration by Schumann dated January 5, 1957 "Annex to 24c and 25a," Schumann estate. The reasons that led to this declaration are not known.

[1314] Correspondence between Schumann and Telschow 1947/48, AMPG, III. Abt., Rep. 83, No. 286. It is interesting that the short note refers to the report "Reichweitengeschoss," but this document does not exist in the Telschow estate. A copy was found in the Schumann estate, with a handwritten note on the date of delivery to "Porhase," intended for the recipient Groves.

[How much information from Schumann was forwarded to Leslie Groves and the United States?]

Heinrich Klein. 1977. *Vom Geschoß zum Feuerpfeil: Der große Umbruch der Waffentechnik in Deutschland 1900–1970: Eine Dokumentation.* Stuttgart: Motorbuch. pp. 96–97.

[Heinrich Klein (German, 19??–19??) led the Rheinmetall-Borsig team that created the Rheintochter two-stage, radio-guided, surface-to-air missile, which was first demonstrated in 1943 (p. 1912). Klein's team also created the larger Rheinbote four-stage missile, first launched in 1943 (p. 1913) [Klein 1977; Margry 2001; Mills 2020, 2022]. In fact, according to a 1947 French military document, during the war Klein was even personally involved in "the construction of flying rockets... capable of crossing the Atlantic in 40 minutes" (p. 5452).]

Mitte Mai 1945, nach der Kapitulation Deutschlands, wurde der Verfasser durch eine gemischte amerik.-engl.-austral. technische Kommission auf dem Schießplatz Unterlüss über die neuen Waffenentwicklungen in Deutschland befragt. Zuvor hatte die Kommission die gesamten Einrichtungen des Meßhauses, die Laborieranstalt und der Füllanlage Neulüss besichtigt und natürlich Meßgeräte und Munition durch ein englisches Truppenkommando sicherstellen lassen. Bei der Besichtigung der Laborieranstalt war die Kommission auch auf einige Brennkammern der Flugstufe des "Rheinboten" gestoßen, die mit dem letzten Troß von Leba nach Unterlüss gebracht worden waren. Im Zuge der Befragungen wandte sich der Leiter der Kommission an den Verfasser und fragte nach dem Sinn und Zweck der gesichteten Brennkammern. Die Kommission habe ähnliche Kammern auf der Strecke über Holland in Richtung Antwerpen gefunden.

In mid-May 1945, after the capitulation of Germany, the author was questioned by a mixed American-English-Australian technical commission at the Unterlüss firing range about the new weapons developments in Germany. The commission had previously inspected the entire facilities of the measuring station, the laboratory, and the Neulüss filling plant, and of course had measuring instruments and ammunition that had been secured by an English troop detachment. During the inspection of the laboratory, the commission also came across some combustion chambers from a stage of the "Rheinbote," which had been brought to Unterlüss with the last convoy from Leba. In the course of the questioning, the head of the commission approached the author and asked about the purpose of the combustion chambers he had seen. The commission had found similar chambers along the trajectory towards Antwerp in Holland.

Irgendwelche Einzelheiten waren dem Verfasser über den Einsatz des “Rheinboten” im Westen nicht bekannt geworden, aber es lag nahe, daß es sich um Stufenteile jener Geräte handeln mußte, die für den Einsatz vorbereitet worden waren. Aus der Fragestellung der Kommission war eindeutig zu entnehmen, daß ihnen das Gerät vollkommen unbekannt war. Sie wollten es zunächst auch nicht glauben, daß das Stufenprinzip für Raketen in Deutschland bereits gelöst wäre, ließen sich dann aber später an Hand einigen Erklärungen davon überzeugen. Mehrere Male während dieser Befragung sprach die Kommission davon, ob der “Rheinbote” die Rakete gewesen wäre, die mit einem atomaren Sprengkopf versehen werden sollte. Auf diese Frage konnte der Verfasser keine Antwort geben, da ihm nicht bekannt war, daß man den Nutzlastkopf dieser Rakete für einen besonderen Zweck verwenden wollte. Wie aus einem später mit dem Leiter der Einsatzabteilung, Oberstleutnant Tröller, geführten Gespräch erkennbar wurde, hat tatsächlich die Überlegung bestanden, den “Rheinboten” mit einer atomaren Nutzlast auszustatten. Wieweit dies nach dem Stand der atomaren Technik in Deutschland möglich gewesen wäre, vermag der Verfasser nicht zu beurteilen. Die Mitteilung von Tröller beruhte darauf, daß ihm SS-Obergruppenführer Dr. Kammler ganz real von einer solchen Einsatzmöglichkeit gesprochen hatte.

The author did not know any details about the use of the “Rheinbote” on the western front, but it was obvious that its stages must have been prepared for [combat] use. It was clear from the commission’s questions that the device was completely unknown to them. At first they did not want to believe that the stage principle for rockets had already been solved in Germany, but they were later convinced by some explanations. Several times during this questioning, the commission asked whether the “Rheinbote” would have been the missile to be fitted with a nuclear warhead. The author could not give an answer to this question, as he was not aware that the payload compartment of this missile was to be used for a special purpose. As became clear from a later conversation with the head of the Operations Department, Lieutenant Colonel Tröller, the idea of equipping the “Rheinbote” with a nuclear payload had indeed been considered. The author is not in a position to judge to what extent this would have been possible given the state of nuclear technology in Germany. Tröller’s report was based on the fact that SS-Obergruppenführer Dr. Kammler had actually spoken to him about such a possible use.

[Based on evidence they had seen, this postwar Allied commission was convinced that Germany possessed or would have soon possessed operational nuclear weapons. What exactly was this commission? Where are their reports? What was their evidence?

German officials who would have been in a position to know, including Hans Kammler and Oberstleutnant Tröller, were convinced that Germany possessed or would have soon possessed operational nuclear weapons. Where are the wartime and postwar documents regarding what they knew?

The Rheinbote version deployed during the war only carried 40 kg of payload. Were the Allied and German officials referring to using Rheinbote missiles with each carrying 40 kg of radioisotopes as a radiological weapon? If so, that would imply that Allied and German officials had knowledge of at least one operational German fission reactor, since a fission reactor would be required to produce sufficiently large quantities of sufficiently radioactive isotopes to support such a weapon system.

The known Rheinbote was rushed to deployment and was likely just a technological stepping stone toward a larger solid propellant Rheinbote-series rocket with a larger payload capacity [Georg 2009, pp. 502–504; https://archive.org/stream/WaffenArsenal189/Waffen%20Revue%2084_djvu.txt]. A larger Rheinbote version might have been able to carry the ~300 kg of the small nonspherical fission implosion bomb that was described by other sources (p. 5170).]

HQ CIC, USFET, Region Munich IV, Munich Sub-Regional Office, 25 April 1946. Subject: Wilhelm Voss. Declassified 2006 [NARA RG 263, Entry ZZ-18, Box 133, File Voss, Friedrich Wilhelm].

1. Dr. Wilhelm VOSS reported to this office 24 April 1946. Subject was the director of the Skoda Works and Bruenner Waffenwerke in Prague, Czechoslovakia from 1939–1945. Subject claims that he has valuable information on atom bomb research in Germany. He also states that he has information on a new type torpedo which is radar controlled and leave no trace in water.

2. Dr. Wilhelm VOSS was born 1 July 1896 in Rostock, Mecklenburg. [...] He was one of the founders of Reichswerke Hermann Goering and in 1938 became its commercial director. In 1939 VOSS was appointed director of Skoda and Bruenner Waffenwerke by Goering.

3. Subject states that the two men that were responsible for research on the most secret weapons at Skoda were SS Gruppenfuehrer Prof. KAMMLER and his deputy SS Oberfuehrer PURUCKER. On the 10 May 1945 VOSS and PURUCKER were in Schimelitz, fleeing in the direction of the American troops. PURUCKER was driving a large civilian car which contained many of the plans on the atom bomb. This car plus material fell into the hands of the Russians, and VOSS was separated from PURUCKER. VOSS at present does not know where PURUCKER is located.

4. Subject was held prisoner by the Czechs in the concentration camp Modran. He was released two weeks ago and at present resides in Odelzhausen near Munich. Subject is moving on 25 April 46 to Egern/a, Tegernsee, Seestrasse 68, c/o REINHOLD. CIC in Tegernsee was notified by phone on the 24 April 1946, and VOSS was told to report to CIC Tegernsee immediately on arrival there.

5. VOSS states that the following men know more detailed plans on the atom bomb and other secret weapons.

> a. Director Alfred BAUBIN of the staff of KAMMLER. Middle of March BAUBIN was supposed to have still been in Internment Camp Schtehowitz near Prague. He was slated to be returned to his native Austria.
>
> b. Director ENGEL, manager of research laboratory in Pibrams and closely connected with KAMMLER. VOSS believes that ENGEL escaped from Czechoslovakia and might subsequently have become PW in American hands.
>
> c. Members of the Research Group could be found in the secret "Mitteilungsblatt des Ruestungsministeriums."

[See pp. 4915– 4919 for excerpts from the original German-language interrogation transcript of Voss that is referenced in this document.]

Wilhelm Voss. April 1946 statement [NARA RG 319, Entry A1-134B, Box 831, Folder XE065651 Voss, Wilhelm]. [See photos on pp. 4916– 4919.]

Die zentrale Leitung der Entwicklung und Fertigung der geheimsten Waffen und Geräte lag in den letzten Jahren in Händen des SS-Gruppenführers Prof. Kammler und seiner Arbeitsgruppe. Dabei handelt es sich um die geheimsten Waffen, Geräte und Verfahren, die z.T. tatsächlich eingesetzt wurden, z.T. aber auch nicht mehr zur Anwendung kamen, und zwar auf dem Gebeit der Atomzertrümmerung, der Umwandlung der Elemente, der Atombombe und der Atomenergie, weiter der Raketenwaffen, neuester Antriebkräfte für Flugzeuge, der Fernsteuerung usw. Während auf manchen Gebieten noch bis in die letzte Zeit des Krieges die verschiedenen Wehrmachtsteile unabhängig voneinander arbeiteten, gelang es Kammler, auf seinem Gebiet vor allem die Entwicklungsarbeiten zentral bei sich zu vereinigen. Er war der Vertreter zugleich des Rüstungsministeriums, des Heereswaffenamtes, des Luftfahrtministeriums und der SS. [...]

In the last years [of the war], the central management of the development and production of the most secret weapons and devices was in the hands of SS General Professor Kammler and his working group. These were the most secret weapons, devices, and processes, some of which were actually used, but some of which were not used [in the war], namely in the field of atom smashing, the [nuclear] transformation of elements, the atomic bomb and atomic energy, and also rocket weapons, the latest propulsion systems for aircraft, remote control, etc. While in some areas the various parts of the Wehrmacht worked independently of each other until the last days of the war, Kammler succeeded in centralizing the development work in his field. He was the representative of the Ministry of Armaments, the Army Ordnance Office, the Air Force, and the SS at the same time. [...]

Mir unterstanden ausser den Konzernen der Skoda-Werke und der Brünner Waffen-Werke u.a. auch die Avia-Flugzeug- und Motorenwerke, die elektrotechnischen Werke Krizik, die optischen Werke in Prerau, die Sprengstoffwerke der Explosia in Semtin, die Radio-Slavia in Prag usw. Ich hatte also Spezial-Sachverständige und Spezialwerkstätten aller in Betracht kommenden Gebiete zur Verfügung. Ausserdem habe ich für längerfristige Forschungen und Entwicklungen die Spezialisten in unseren zentralen Forschungs- und Entwicklungswerkstätten in Pibrans konzentriert.

In addition to the Skoda-Werke and Brünner Waffen-Werke groups, I was also in charge of the Avia Aircraft and Engine Works, the Krizik electrotechnical works, the optical works in Prerau, the Explosia explosives works in Semtin, Radio-Slavia in Prague, and so on. I therefore had access to specialized experts and workshops in all relevant fields. I also concentrated specialists in our central research and development workshops in Pibrans for longer-term research and development.

[In this document, Kammler's name is misspelled as "Kammerer." Voss certainly would have known how to spell Kammler's name, so the document appears to have been transcribed by an Allied interrogator from Voss's oral explanation. Kammler's name is spelled correctly in the other documents related to Voss's interrogations, and I have corrected the spelling here to avoid any confusion.

The first paragraph is a very clear statement of the projects under Kammler's control. Voss, who made that statement, was an extremely senior and experienced official in a position to know, as shown by the other paragraph from later in the same document. Note that many of the sites named by Voss were involved in nuclear work, as reported by documents elsewhere in this appendix.

Surely Allied interrogators would ask Voss for much more information about these very hot topics. Where are those more detailed interrogation reports?]

I.) Arbeitsgruppe Kammerer.

Die zentrale Leitung der Entwicklung und Fertigung der geheimsten Waffen und Geräte lag in den letzten Jahren in Händen des SS-Gruppenführers Prof. Kammerer und seiner Arbeitsgruppe. Dabei handelt es sich um die geheimsten Waffen, Geräte und Verfahren, die z.T. tatsächlich eingesetzt wurden, z.T. aber auch nicht mehr zur Anwendung kamen, und zwar auf dem Gebiet der Atomzertrümmerung, der Umwandlung der Elemente, der Atombombe und der Atomenergie, weiter der Raketenwaffen, neuester Antriebkräfte für Flugzeuge, der Fernsteuerung usw. Während auf manchen Gebieten noch bis in die letzte Zeit des Krieges die verschiedenen Wehrmachtsteile unabhängig voneinander arbeiteten, gelang es Kammerer, auf seinem Gebiet vor allem die Entwicklungsarbeiten zentral bei sich zu vereinigen. Er war der Vertreter zugleich des Rüstungsministeriums, des Heereswaffenamtes, des Luftfahrtministeriums und der SS. Prof. Kammerer hielt sich zuletzt hauptsächlich in Prag auf. Er ist in der Nähe von Prag am 9. Mai 1945 durch Selbstmord verschieden.

Sein Vertreter in der Leitung der Arbeitsgruppe war der SS-Oberführer Purucker. Er war Generaldirektor der Industriewerke Spandau (?), eines Unternehmens, das zum Rüstungsministerium gehörte, und gleichzeitig seit Jahren der Verbindungsmann des Rüstungsministeriums beim Heereswaffenamt. Als sich in den Tagen des 9., lo. und 11. Mai 1945 ein Teil der deutschen Truppen und der Zivilisten-Trecks aus dem Raume um Prag herum nach Westen in Richtung auf die USA-Truppen zurückzog, fand sich am lo. Mai 1945 auch Purucker in Schimelitz bei der

amerikanischen Sperre auf der Strasse Pibrams-Strakonitz ein und versuchte, mit seinem grossen Wagen, der nach seinen Erklärungen mit Material Kammerers voll beladen war, die Sperre zu passieren, um sich und sein Material im Hauptquartier in Winterberg den Amerikanern zu übergeben. Das gelang ihm nicht, da das Passieren der Sperre strikte verweigert wurde.

Am 12. Mai 1945 wurde die Masse der im dortigen Raume befindlichen Truppen und Zivilisten in Anwesenheit einiger weniger USA-Einheiten von russischen Truppen übernommen. Purucker und ich haben versucht, trotzdem noch in letzter Stunde das Material Kammerers den USA-Streitkräften zu übergeben. Wir haben zu diesem Zweck einen amerikanischen Offizier herbeigeholt, ihm die Sachlage kurz erklärt und ihn gebeten, seinen Kommandeur zu unterrichten. Der Leutnant versprach, spätestens innerhalb einer Stunde zurückzukommen. Das geschah aber nicht. Als nach zwei Stunden russische Truppen in das Grundstück, in dem wir uns befanden, eindrangen, wandte sich Purucker an einen russischen Hauptmann und machte diesem von seinem Material Meldung. Der russische Offizier hat sofort das Hauptquartier in Stary-Sedlece orientiert und kam sehr bald mit der Nachricht zurück, dass Purucker mit seinem Material binnen kurzer Zeit zum russischen General geführt würde. Wir sind dann mit mehreren deutschen Offizieren und Zivilisten nach Zlabings (Zlavonice) überführt worden. Dort wurde Purucker unverzüglich verhört, der Wagen mit dem Material wurde ihm abgenommen und Purucker selbst wegtransportiert, - wohin, ist mir nicht bekannt, da ich mich, als Purucker mit den russischen Offizieren verhandelte, schon von ihm trennte und von Zlabings aus dann in ein russisches Lager überführt wurde. Welches Material Purucker im einzelnen bei sich hatte, kann ich nicht sagen. Nach seinen Erklärungen waren es die wichtigsten Akten, Zeichnungen und

sonstigen Unterlagen der Arbeitsgruppe Kammerer. Ich kann auch über die Arbeiten Kammerers im einzelnen nichts sagen, weil ich der Arbeitsgruppe nicht angehörte. Ich weiss aber aus den Mitteilungen einiger meiner Herren, die in den von mir geleiteten Betriebe arbeiteten und die auch bei Kammerer tätig waren, dass von der Arbeitsgruppe Kammerer konzentriert die Gebiete bearbeitet wurden, die ich oben angegeben habe. Nähere Mitteilungen darüber könnten folgende Personen machen:

1.) die Mitglieder der Arbeitsgruppe (zu erfahren aus dem geheimen Mitteilungsblatt des Rüstungsministeriums),

2.) Direktor Alfred Baubin (Prag, Skoda-Werke, Jungmannstr.), der in den letzten Monaten den Arbeitsstab Kammerers in Prag leitete. Baubin ist nach meinen Informationen im vorigen Sommer und Herbst in Prag sehr oft von Russen und auch vom tschechischen MNO verhört worden. Er befand sich, als ich aus der CSR entlassen wurde, Mitte März dieses Jahres noch in einem Lager Schtehowitz bei Prag und sollte, wie ich hörte, in seine Heimat nach Österreich entlassen werden.

3.) Direktor Engel, der meine zentrale Forschungs-und Entwicklungswerkstätten in Pibrams leitete und der in dauerndem Kontakt mit Kammerer stand. Engel ist, wie ich annehme, rechtzeitig aus der CSR geflüchtet und dürfte von den USA-Streitkräften gefangengenommen sein.

NARA RG 319, Entry A1-134B, Box 831, Folder XE065651 Voss, Wilhelm

Figure D.929: Wilhelm Voss. Excerpts from April 1946 statement [NARA RG 319, Entry A1-134B, Box 831, Folder XE065651 Voss, Wilhelm].

- 8 -

8.) Eine Vorrichtung, die den Panzern ein treffsicheres Schiessen aus der Bewegung gewährleistet.
9.) Höchstwirksame Sprengstoffe.
10.) Schalldämpfende und lichtfreie Sprengstoffe.
11.) Rückstossfreie Raketengeschütze für Flugzeuge.
12.) Automatische Kanonen für 4, 5 und 7,5 cm.
13.) 3 cm Flak, als Zwilling und Vierling, erheblich besser als die 3,7 cm deutsche Flak.
14.) Elektrische Zünder für Hohlladung und Keilgeschoss, und anderes mehr.

Ein grosser Teil der unter mir tätigen deutschen und tschechischen Forscher und Konstrukteure dürfte sich entweder in amerikanischer Gefangenschaft befinden (soweit es sich um Deutsche handelt), oder ist (das gilt für die Tschechen) aus ihren Positionen entfernt worden. Die Letzteren werden aber zweifelsohne von der tschechischen oder russischen Armee eingesetzt werden, da sie erstklassige Fachleute sind.

Figure D.930: Wilhelm Voss. Excerpts from April 1946 statement [NARA RG 319, Entry A1-134B, Box 831, Folder XE065651 Voss, Wilhelm]. Note the manufactured items 9 ("highest energy explosives") and 14 ("electric detonators for shaped charge and wedge projectiles").

Wilhelm Voss. Statement. 18 September 1946. The first two pages are present in the U.K. copy of this document [TNA FO 1031/64] but appear to have been redacted in the U.S. copy [NARA RG 263, Entry ZZ-18, Box 133, File Voss, Friedrich Wilhelm].

1. Professor Kammler (G).

He was the Head of a staff of specialists who developed highly secret weapons and war-equipment. Whereas up to a recent date each Branch of the Wehrmacht and its competent authorities had their developments carried out separately, Kammler succeeded in creating in his field a centralized command for all Branches of the Wehrmacht. His field consisted mainly of V-weapons, rocket apparatus, remote control, atomic energy, jet-propulsion and other similar subjects.

According to my information, Kammler, who shifted his office to Prague during the last month of the war—committed suicide on May 9th near Prague. His first assistant and second in command was

2. Generaldirektor (General Manager) [Erich] Purucker (G).

He was General Manager of the Vereinigte Industriewerke, Spandau, and of the Berliner Spreewerk (production of guns and ammunition). He was in the first place the liaison between SS, Heereswaffenamt (Army Ordnance Branch) and Ruestungsministerium (Ministry of Armaments and War Production) and in the end he became the assistant of Kammler. On May 10th I met him at the American demarcation line outside Schimmelitz on the road Pibrams–Strakonitz, where a large convoy of civilian lorries and military formations stopped, in order to be taken over and directed into the Reich by American troops. We stayed there until May 12th. On that day an order was given all of a sudden to the effect that not the Americans, but approaching Russian Formations would take us over. Therefore Purucker and I tried to hand over to the Americans the very bulky material of the staff of scientists under Kammler, which Purucker had packed and carried with him in a large lorry and in order to hand the material over to the Americans, Purucker called an American officer. This officer promised to inform his Commanding Officer according to our wish and to fetch us and the material within an hour latest. Apparently, however, he did not realize the importance of this matter, because he did not come back. Therefore Purucker handed all his material over to Russian officers. I was still with him on May 15th in the Russian camp in Zlavonice at the southern border of Bohemia. Purucker was interrogated there several times by night by the Russians and one day he was moved together with his material. Where—I don't know—but recently I heard by chance that he is working in Moscow and that his family has joined him there.

3. Ing. Karel Staller (C)

This man is the most versatile and intelligent designer and scientist I ever met. Towards the end he became second General Manager of the Bruenner Waffen-Werke under me—worked, however, as before, mainly in the field of research and development. He himself was the designer of the famous British machine-gun (Bren ZB 26 and 37) and he carried out more or less himself all developments within the Bruenner Waffen-Konzern in the fields of optics, machine-construction, construction of arms, fuzes, ammunition, rocket-projectors, etc. [...]

4. Fritz (?) [actually Rolf] Engel (G)

This man was, if I am not mistaken—until 1942/43 Head of the experimental workshops at Helamuende, which he founded himself. Then I took him over (with the experimental workshops) and made him Chief of our research institute at Pibrams. Engel was a specialist for many years in the field of rockets and he was a member of the Central Commission for rocket-research, Berlin. For a long time he worked together with Kammler, and he knew almost everything of the secret research and development work, especially because he was the President of a special Commission which had to carry out the entire calculations in the chemical and physical fields with regard to ballistics of special weapons and apparatus. Engel and his wife lived in Pibrams. I suppose that he escaped in time across the American demarcation line into Germany and that he lives probably somewhere in the American Zone.

5. Ing Odstracil (C)

After Staller he is, according to my opinion, the best scientist and designer of the Bruenner-Waffen-Konzern, of which he was the official Chief designer. He worked mainly in the fields of rocket projectors, automatic weapons, fuzes and ammunition. [...]

6. Ing. Adolf Vambersky (C).

This man was General Manager of the Skoda Konzern (Combine) and in that capacity he was more or less the Chief of research and development in all fields with regard to the combine. [...]

7. Ing. Alesch (C).

Until May 1945 he was Chief of Explosia AG and Synthesia AG He is a former Austrian Officer of the Engineers in Blumen. Alesch is an excellent expert in the field of high explosives, therefore he directed our latest developments in high explosives. [...]

8. Dr. Kappel (G).

He, as a chemist was in charge of the laboratories of our plants for high-explosives in Semtin. He himself was a scientist and the inventor of the latest patents. [...]

11. Ing. Novy (C)

He was the Chief of our foundries, including the attached plants and the casting houses. He was a specialist in the field of light metal. He is an excellent expert as well as technician. [...]

12. Professor Dr. Maurer (G).

Before he worked with Krupp's, then he was advisor with the Skoda Konzern in all questions of metallurgy and foundries. He was in the first place a University professor (ordentlicher Professor) at the Academy for Mining in Freiberg/Saxony [see pp. 3433–3437, 3456–3416, 3708]. As far as I know he had to resign at the instigation of the Russians. He is an excellent scientific capacity on iron and steel including the working-up process and he is also very practical-minded. [...]

14. Dr. Pavlicek (G).

He was the Chief of the Optiko-Techna.—the optical plants of the Bruenner Waffen Konzern in Prerov. His field was mainly research and development. He was also informed with regard to many particulars concerning his field, inside Germany, as he had to function at general conferences and discussions in these questions, created by various firms under the leadership of Zeiss. [...]

[For the German-language original of this document, see pp. 4923–4929.

This document supports the story of Purucker fleeing with (atomic bomb) plans in his car and being forced to surrender to Russians instead of Americans.

It also provides more information on Rolf Engel and other experts working in wartime Czechoslovakia, and demonstrates that their expertise covered many of the areas necessary to build an atomic bomb. See also pp. 3751–3754.]

NARA RG 319, Entry A1-134B, Box 831, Folder XE065651 Voss, Wilhelm

Forscher und Konstrukteure

1. Professor Kammler (G)

Er war der Leiter eines besonderen Arbeitsstabes, dem die Entwicklung geheimster Waffen und Kriegsgeräte oblag. Während bis i in die letzte Zeit hinein die einzelnen Wehrmachtsteile und die dafür zuständigen Behörden ihre Entwicklung getrennt voneinander durchführen ließen, war es Kammler gelungen, auf seinem Arbeitsgebiet eine zentrale Führung für alle Wehrmachtsteile zu erreichen. Sein Arbeitsgebiet war in der Hauptsache V-Waffen, Raketengeräte, Fernsteuerung, Atomenergie, Strahlantrieb und dergleichen mehr.

Nach meinen Informationen hat sich Kammler, der in den letzten Monaten des Krieges seinen Dienstsitz nach Prag verlegt hatte, am 9. Mai 1945 in der Nähe Prags das Leben genommen. Sein erster Mitarbeiter und Stellvertreter war

2. Generaldirektor Puruker (G)

Dieser war Generaldirektor der Vereinigten Industriewerke in Spandau und des Berliner Spreewerkes (Herstellung von Geschützen und Munition). Er war in der Hauptsache der Verbindungsmann zwischen SS, Heereswaffenamt und Rüstungsministerium und nicht zuletzt Mitarbeiter von Kammler. Am 10.Mai 1945 kam ich mit ihm an der amerikanischen Demarkationslinie vor Schimmelitz auf der Straße Pribrams - Strakonitz zusammen, wo eine Menge Ziviltrecks und militärischer Verbände hielten, um von den Amerikanischen Truppen übernommen und in das Reich durchgeschleust zu werden. Wir verblieben dort bis zum 12. Mai. An diesem Tage kam plötzlich die Anordnung durch, daß wir nicht von den Amerikanern, sondern von den russischen Verbänden, die im Anrücken waren, übernommen würden. Puruker und ich haben dann noch versucht, das sehr umfangreiche Material des Arbeitsstabes Kammler, das P. in einem großen Wagen mit sich führte, den Amerikanern zu übergeben und zu diesem Zweck einen amerikanischen Offizier herangerufen. Dieser versprach, unserem Wunsche gemäß, seinen Kommandeur zu verständigen und dann uns mit dem Material spätestens innerhalb einer Stunde zu holen. Offenbar ist ihm aber die Bedeutung der Sache nicht klar geworden, jedenfalls ist er nicht wiedergekommen. P. hat dann sein gesamtes Material russischen Offizieren übergeben. Ich war zuletzt e mit ihm am 15. noch im russischen Lager in Zlavonice an der böhmischen Südgrenze zusammen. Dort wurde Puruker mehrfach nachts von den

- 2 -

Russen verhört und eines Tages mit seinem Material abtransportiert. -Wohin, weiß ich nicht-, ich habe aber zufällig vor kurzem gehört, daß er in Moskau tätig ist und auch seine Familie nach dorthin hat nachkommen lassen.

3. Ing. Karel Staller (C)

Dieser ist der vielseitigste und begabteste Konstrukteur und Forscher, den ich überhaupt kenne. Er war zuletzt Stellvertretender Generaldirektor der Brünner-Waffen-Werke unter mir, hat aber nach wie vor hauptsächlich auf dem Gebiet der Forschung und der Entwicklung gearbeitet. Er selbst war Konstrukteur des bekannten englischen Maschinengewehrs (Bren ZB 26 und 37) und hat außerdem eigentlich sämtliche Entwicklungen, die im Rahmen des Brünner-Waffen-Konzerns vor sich gingen, mehr oder weniger selbst durchgeführt, und zwar sowohl auf demGebiet der Optik, wie des Maschinenbaues, der Waffenkonstruktion, des Zünders, der Munition, der Raketengeräte etc.

Staller habe ich zuletzt Ende des Jahres 1945 in Prag, als ich in Untersuchungshaft war, gesprochen. Er ist Mitte des Jahres 1945 bei den Brünner-Waffen-Werken ausgeschieden (ich nehme an, weil er nicht kommunistisch eingestellt ist) und hatte nur eine beratende Tätigkeit bei der Organisation der Metallverarbeitenden Industrie in Prag. Er sagte mir damals, daß er ins Ausland gehen möchte.

4. Fritz (?) Engel (G)

Dieser war, wenn ich nicht irre bis 1942/43 Leiter der Versuchswerkstätten in Helamünde, die er auch selbst gegründet hatte.

Dann habe ich ihn übernommen (mit den Versuchswerkstätten) und ihn zum Leiter unseres Forschungsinstitutes Pribrams gemacht. Engel war Spezialist seit vielen Jahren auf dem Gebiet des Raketenwesens und war Mitglied der zentralen Kommission in Berlin für dieses Gebiet. Er hat auch lange mit Kammler zusammengearbeitet und war über wesentliche Teile der geheimsten Forschung und Entwicklung unterrichtet, insbesondere auch deshalb, weil er Vorsitzer einer Sonderkommission war, die die gesamten Berechnungen auf chemischem und physikalischem Gebiet für die Ballistik der Sonderwaffen und Sondergeräte durchzuführen hatte.

Engel wohnte mit seiner Frau in Pribrams, ich nehme an, daß er rechtzeitig über die amerikanische Demarkationslinie nach Deutschland geflohen ist und wahrscheinlich sich in der amerikanischen Zone aufhält.

- 3 -

5. Ing. Ostračil (C)

Diesen halte ich nach Staller für den besten Forscher und Konstrukteur des Brünner-Waffen-Konzerns, dessen offizieller Chefkonstrukteur er war. Er hat vor allem auf dem Gebiet der Raketengeräte, der automatischen Waffen, der Zünder und der Munition gearbeitet.

Nach meinen Informationen war er der neuen Richtung der ČSR nicht genehm, mußte deshalb bei dem Brünner-Waffen-Konzern ausscheiden und hatte keine neue Beschäftigung. Seine Wohnung befand sich in Prag.

6. Ing. Adolf Vambersky (C)

Dieser war Generaldirektor des Skoda-Konzerns und leitete auch in dieser Eigenschaft hauptsächlich die Forschung und Entwicklung auf allen Arbeitsgebieten des Konzerns. Er war früher selber Konstrukteur gewesen und hatte die neuesten Skoda-Lokomotiven und die bekannten schweren 42 cm Mörser des ersten Weltkrieges konstruiert. Er ist nach der Revolution vom Mai 1945 in Prag noch einige Monate Generaldirektor des Skoda-Konzerns geblieben, dann aber verhaftet worden. Im März 1946 wurde er vom tschechischen Nationalgericht zu einem Jahre Gefängnis und teilweisen Einziehung seines Vermögens verurteilt, mit der Begründung, daß er mit einigen anderen führenden Tschechen im April 1945 versucht hat, im amerikanischen Hauptquartier die Besetzung Prags durch die Amerikaner statt durch die Russen zu erreichen. Als ich von Prag freigelassen wurde, befand sich Vambersky noch im Krankenhaus. Wo er jetzt ist, weiß ich nicht. Er wohnte auf einem Gut in der Nähe von Tabor (CSR).

7. Ing. Alesch (C)

Er war bis zum Mai 1945 Zentraldirektor der Explosia AG. und der Synthesia AG., früher Österreichischer Genie-Offizier in Blumau. Alesch ist ein ausgezeichneter Fachmann auf dem gesamten Gebiet der Explosivstoffe, der auch unsere neuesten Entwicklungen dieser Art leitete. Auch er wurde aus seiner Stellung von der neuen tschechischen Richtung entfernt und hat meines Wissens keine neue Tätigkeit übernommen. Er wohnte in Semtin bei Pardubitz.

6.

- 4 -

8. Dr. Kappol (G)

Dieser leitete als Chemiker die Laboratorien unserer Sprengstoffwerke in Semtin und war selber Forscher und Entwickler, auch Erfinder neuester Patente. Er hat als Deutscher sicher nicht in der Tschechei bleiben können. Wie ich annehme, ist er über die amerikanische Demarkationslinie nach Deutschland geflohen und dürfte sich ebenfalls in der amerikanischen Zone aufhalten. Er wohnte vorher in Semtin.

9. Ing. Zubaty (C)

Dieser leitete unsere Panzerwerke in Pilsen beim Skoda-Konzern und führte selber die neuen Entwicklungen auf dem Gebiet des Panzerwesens durch. Ein ausgezeichneter Konstrukteur auf dem ~~Gebiet~~ Ganzen wie in allen Einzelheiten eines modernen Panzers, einschließlich Motoren. Auch er hat seinen Posten verloren und keine neue Tätigkeit. Er wohnte in Pilsen.

10. Dr. Jurczyk (G)

Er war stellvertretender Leiter unserer Geschützfabriken in Pilsen beim Skoda-Konzern, einschließlich der Versuchswerkstätten, und war selber Forscher und Konstrukteur. Er hat z.B. die neusten schweren Minen (3o,5 und 42 cm mit einer Distanz bis zu 3o Km) konstruiert.

11. Ing. Novy (C)

Dieser leitete unsere Hütte mit den zugehörigen Werken einschließlich der Gießereien und war ein Spezialist auf dem Gebiete des Leichtmetalls. Er ist einhervorragender Fachmann, sowohl Techniker wie Praktiker. Er wohnte in Pilsen, ob er dort noch tätig ist, weiß ich nicht.

12. Professor Dr. Maurer (G)

Dieser war früher bei Krupp tätig und dann Adviser beim Skoda-Konzern für alle Metall- und Hüttenfragen. Er war in der Hauptsache ordentlicher Professor an der Bergakademie in Freiberg in Sachsen und wie ich hörte ist er auf Veranlassung der Russen dort ausgeschieden. Er ist ein ausgezeichneter Forscher gerade auf dem Gebiet von Eisen und Stahl und ihrer Verarbeitung und hat auch einen sehr guten praktischen Blick. Wo Maurer sich zur Zeit aufhält, ist mir nicht bekannt.

- 5 -

13. **Ing. Kautkay (Ö)**

Er war der Spezialist des Brünner-Waffen-Konzerns für automatische Waffen und war als solcher bei der Entwicklung dieser Geräte maßgebend beteiligt. Seine Wohnung befand sich in Brünn. Was aus ihm seit Mitte 1945 geworden ist, weiß ich nicht.

14. **Dr. Pavliček** (G)

Er leitete die Optiko-Techna, die Optischen Fabriken des Brünner-Waffen-Konzerns in Prerov und befaßte sich in der Hauptsache mit der Forschung und Entwicklung. Er war auch über sehr viele reichsdeutsche Dinge auf diesem Gebiet im Bilde, weil er bei gemeinsamen Aufgaben, die für mehrere optische Firmen unter Führung von Zeiss gestellt wurden, mitzuwirken hatte. P. wohnte in Prerov, ob er sich dort noch aufhält oder tätig ist, habe ich bisher nicht feststellen können.

15. **Ing. Löhrl (G)**

Dieser war der Spezialist für Munition, sowohl in der Entwicklung wie in der Fertigung in Pilsen bei den Skodawerken seit mehreren Jahrzenten. Als Deutscher hat er Pilsen verlassen müssen, wahrscheinlich befindet er sich in der amerikanischen Zone.

16. **Ing. Stancovič** (Serbe)

Er war der Generaldirektor des Vistad-Konzerns (Sitz Belgrad, Hauptwerk in Valjevo). Als solcher leitete er den gesamten Konzern, war aber selber speziell Forscher, Entwickler und Konstrukteur auf dem Gebiet des Maschinenbaues, sowie von Bomben und Munition.

17. **Ing. Noak (C)**

Er war der Leiter der Flugzeugwerke Avia des Skoda-Konzerns in Prag-Letnian. In der Hauptsache war er Konstrukteur, u.a. der früheren tschechoslowakischen Flugzeugtypen insbesondere auch des sehr erfolgreichen bekannten tschechischen Kunstflugzeuges. Er wohnte in Prag. Wo er sich jetzt aufhält, ist mir unbekannt.

18. **Ing. Ledvinka** (Österreicher)

Dieser war der Chefkonstrukteur der Ringhoffer-Tatrawerke. Er hat selber eine Reihe modernster Auto- konstruiert, u.a. die bekannten Tatrawagen, und auch modernste Wagen und Motoren überhaupt entwickelt. Ende des Jahres 1945 befand er sich in Untersuchungshaft in Wesseldorf (Tschechoslowakei).

- 6 -

19. Fliegerstabsingenieur **Zeyss**

Er war der zentrale Bearbeiter der Raketengeräte für die Luftwaffe und für das Heereswaffenamt, arbeitete im engsten Zusammenhang mit den von mir geleiteten Konzernen und vor allem auch mit Direktor Engel, dessen Kommission er angehörte.

Wo Zeyss sich jetzt aufhält, ist mir nicht bekannt.

20. Direktor Ing. **Jestrabek**

Er war leitender Konstrukteur bei meinen Brünner-Waffen-Werken und leitete in Brünn auch eine besondere Versuchswerkstätte. Er war selber Konstrukteur. Spezialgebiet: Automatische Waffen, Sondermunition und vor allem 3 cm Flak.

Jestrabek wohnte in Brünn, hielt sich im April noch in Prag auf und dürfte jetzt auch in Deutschland sein.

21. Walter **Soost**

Er war Konstrukteur vor allem auf dem Gebiet der Optik, der Schallmessungen u.a. bei unserer Optiko-Techna (Brünner-Waffen-Konzern in Prerov.)

Soost ist meines Wissens noch in der Tschechoslowakei gefangen, und zwar in einem Lager bei Kollin.

22. Baron Hans **Ringhoffer**

Er war einer der ersten Fachleute auf dem Gebiete der Personen- und Lastwagen und auch des Waggonbaues, von internationalem Ruf.

Im Frühjahr 1946 befand er sich noch in Haft in dem Lager Prag-Hagibor.

23. Dipl.-Ing. **Gold**

Er war Generaldirektor der Ferdinand-Nord-Bahn (Kohlenbergbau). Einer der ersten Fachleute auf dem Gebiet des Kohlenbergbaues, der Kohlenverwertung, Verkokung etc.

Er wohnte bis zum Frühjahr 1945 in Mährisch-Ostrau, ist aber rechtzeitig nach Deutschland geflohen.

24. Dipl.-Ing. **Klima**

Dieser war Leiter der zentralen Betriebsdirektion des Skoda-Konzerns in Prag. Spezialist der Fertigung von Waffen und Maschinen aller Art. Auch guter Organisator für die Betriebsfertigung.

Er ist nach meinen Informationen nach Deutschland geflohen.

25. Direktor Ing. **Sonnevend**

E

- 7 -

25. Direktor Ing. **Sonnewend**

Er war Direktor der Skoda-Werke in Dubnica (Slowakei). Ein Spezialist auf dem Gebiete der Fertigung.

Sonnewend wohnte mit seiner Familie in Dubnica, ist aber im Frühjahr 1945 nach Österreich geflohen und soll sich dort im Aussee aufhalten.

26. Direktor Dr. **Witt**

Er war Leiter der Brünner-Waffen-Werke in Povaska/Bistrica (Slowakei), Betriebsspezialist.

Witt wohnte mit seiner Familie in Povaska/Bistrica, dürfte aber rechtzeitig nach Deutschland geflohen sein.

27. Direktor Ing. **Gerwealühr**

Er war früher bei den Rheinmetall-Werken tätig, seit den letzten Jahren bei den Skoda-Werken als Spezialist für die Fertigung von Panzern und Geschützen.

Gerwealühr war bis zum Schluß in Prag. Wo er sich jetzt aufhält, ist mir nicht bekannt.

28. Direktor Ing. **Haske**

Er leitete die Skoda-Werke in Prag/Smichov. Spezialist auf dem Gebiet der Werkzeugmaschinen- und der Geschoßfertigung.

Wo er sich jetzt aufhält, ist mir unbekannt.

29. Direktor Ing. **Dostal**

Er leitete die zentrale Betriebsdirektion der "Böhmisch-Mährischen" in Prag. Spezialist auf dem Gebiet der Fertigung.

Aufenthaltsort mir unbekannt.

30. Direktor Dipl.-Ing. **Lindenberg**

Dieser leitete unsere Flugzeugmotorenwerke in Prag-Letnian. Spezialist für die Fertigung von Flugzeugmotoren.

Lindenberg war bis Ende März in Haft in der Tschechoslowakei, ist dann nach Deutschland gekommen und hält sich im Tegernsee auf. Er ist meines Wissens im Motor-Pool der US-Army in Bad Wiessee/Tegernsee tätig.

Dr. Wilhelm Voss den 19. Oktober 1946

An
D.P.D.S. - F.I.A.T.

Höchst via Commandant Dustbin

Ich bitte hiermit um meine Entlassung aus der Haft. Zur Begründung weise ich in der Hauptsache auf Folgendes hin:

1. Ich war bereits 11 Monate, vom Mai 1945 bis Ende März 1946 in Haft in der Tschecho-Slowakei. Während dieser Zeit sind meine persönlichen Verhältnisse und insbesondere auch meine Tätigkeit als Chef des Skoda- und des Brünner-Waffen-Konzerns (1939 - 1945) eingehend untersucht, und ich bin immer wieder verhört worden (von der Gendarmerie, der Polizei und auch vom Innenministerium).

   Ende März 1946 wurde ich nach Deutschland entlassen.

   Diese Tatsache ist wohl der beste Beweis dafür, daß man mir nicht das Geringste vorzuwerfen hat, denn sonst wäre ich sicher nicht entlassen worden. Wie mir amtlich mitgeteilt wurde, lag trotz aller Rundfragen keinerlei Anzeige oder Beschwerde gegen mich vor. Im Gegenteil, die befragten Nationalausschüsse und Betriebsräte hatten ausdrücklich zu meinen Gunsten Stellung genommen.

2. In den von mir geleiteten Werken wurden keine ausländischen Arbeiter beschäftigt, auch keine angefordert. Ich habe mich darüber hinaus mit Erfolg dafür eingesetzt, daß keine Tschechen aus unserem Bereich nach Deutschland dienstverpflichtet wurden, was besonders schwierig war, als es sich um tschechische Konstrukteure und Specialisten handelte. Außerdem habe ich zu Weihnachten 1944 dafür gesorgt, daß ins Reich dienstverpflichtete tschechische Studenten mit Wagen der Skoda-Werke nach Hause transportiert wurden, wo sie dann natürlich auch blieben.

3. Soweit es in meinen Kräften stand, habe ich der tschechischen Bevölkerung Hilfe geleistet, wann und wo immer es nur möglich war. Große Teile meines Sekretariats in Prag waren mit nichts anderem beschäftigt, als für Tschechen bei deutschen Dienststellen zu intervenieren, und zwar naturgemäß in erster Linie für Arbeitnehmer unserer Werke und ihre Angehörigen, darüber hinaus aber auch für Tschechen, die außerhalb meines Tätigkeitsbereiches standen und die sich an mich gewandt hatten, weil ich im Protektorat dafür bekannt war, daß ich mich der Tschechen annahm, soweit es in meinen Kräften stand.

   Ich habe grundsätzlich verboten, Werksangehörige bei der Polizei anzuzeigen.

   Es steht nachweislich fest, daß mir viele hundert Tschechen, Männer, Frauen und Kinder Freiheit und Leben zu verdanken haben. Ich habe eine große Anzahl von Tschechen aus den Gefängnissen und Konzentrationslagern befreit, sie bei der Geiselaktion Franks vor dem Erschiessen bewahrt, usw.

   Um nur ein Beispiel von vielen zu nennen:
   Im Jahre 1944 sollte ein führender Tscheche, Ingenieur Karel Staller, mit seiner Familie erschossen werden, weil ein Agent glaubhaft gemeldet hatte, daß der tschechische Ingenieur eine wichtige Geheimwaffe an die Alliierten verraten hatte. Trotzdem habe ich mich aus gründender Menschlichkeit für den Betreffenden und seine Familie eingesetzt, K.H. Frank gegenüber die persönliche Bürgschaft für Staller übernommen und ihn sowie seine Familie gerettet. Hiervon habe ich Staller außerdem Mitteilung gemacht und ihn gewarnt.

Figure D.938: Wilhelm Voss. Excerpts from October 1946 statement [NARA RG 319, Entry A1-134B, Box 831, Folder XE065651 Voss, Wilhelm].

[According to official histories, Hans Kammler died in early May 1945. However, documents in U.S. government archives prove that he surrendered to U.S. forces in May 1945 and was alive and being interrogated by the United States long after the war.]

Albert Speer. 1981. *Infiltration: How Heinrich Himmler Schemed to Build an SS Industrial Empire.* p. 243

[...] Kammler [...] came to me in early April in order to say goodbye. For the first time in our four-year association, Kammler did not display his usual dash. On the contrary, he seemed insecure and slippery with his vague, obscure hints about why I should transfer to Munich with him. He said efforts were being made in the SS to get rid of the Führer. He himself, however, was planning to contact the Americans. In exchange for their guaranty of his freedom, he would offer them the entire technology of our jet planes, as well as the A-4 rocket and other important developments, including the transcontinental rocket. For this purpose, he was assembling all development experts in Upper Bavaria in order to hand them over to the Americans.

Hans Kammler's Adjutant Heinz Schürmann. 6 November 2003 filmed interview with Heiko Petermann [courtesy of Heiko Petermann].

[Kammler's last words to Schürmann before leaving him on 4 May 1945:]

Wenn es heisst, Hänschen ist tot, ist Hans noch lange nicht tot.	If it is said that little Hans is dead, Hans is far from dead.

7 May 1945 memorandum discovered by or provided to Gerald Fleming (Surrey University). What is the original archival source for this document? [It was published in **Reuter et al. 2019, p. 168**].

[Redaction 1]

TOP SECRET

[Redaction 2]

7 May 1945

BY DIPLOMATIC POUCH

SUBJECT: Interrogation Report **[Redaction 3]** HANS KAMMLER

General der S.S. KAMMLER (chief of all V-weapons production) office at 7, Taunusstrasse, Berlin - Grunewald.

Age: 43 and party member since 1932. Dr. Ing. KAMMLER is a trained architect by profession and was head of all secret weapons projects including the V-1 and V-2. He further claims to have been head of **[Redaction 4]** project based at the **[Redaction 5]**. CIC Officer is in possession of documents from KAMMLER which may prove to be of considerable value.

Dr. KAMMLER surrendered 6 May with other named persons attached. Dressed in Heer uniform he later identified himself to an officer of **[Redaction 6]**. By way of special order KAMMLER is to be transferred immediately to KOHNSTEIN, Germany for purposes of detailed interrogation and evaluation of underground weapons research and production facilities.

DETAILED REPORT: At the suggestion of the investigating officers KAMMLER is preparing a detailed report (in German). This is to include the following:

Secret weapons development

[Redaction 7]

Underground research and production facilities

Security measures concerning the above

[Redaction 8]

[See document photo on p. 4934 (courtesy of Rainer Karlsch).

This document was typed in a monospace font, with an equal amount of space for every character. It used a single space after each period. The number of characters in each redacted phrase gives some clue as to what that phrase could have been.

Redaction 1 seems to have been added sometime after the document was typed and was probably an identification number for the document within an archive. That information was apparently removed to prevent investigators from locating the source of the document, verifying its authenticity, and finding other related documents.

Redaction 2 was the name of the organization that created this memorandum. Again, it was probably removed to prevent investigators from locating the source of the document, verifying its authenticity, and finding other related documents. Based on the style of the document, it was created by the U.S. military. From information later in the document, the creating organization was either the U.S. Army Counter-Intelligence Corps (CIC) itself or some other organization that collaborated with or oversaw CIC.

Redaction 3 contained 6 characters between "Report" and "HANS", including any spaces (which I will show as "_") before, after, and in between. Presumably it named the organization that interrogated Kammler and was redacted for that reason. The most likely answer was "s_CIC_" or ":_CIC_". CIC is named later in the document as being involved in possessing information from Kammler. It appears very sloppy or hasty that one mention of CIC was redacted while the other was not.

Redaction 4 contained 16 characters between "of" and "project", including any spaces before, after, and in between. It named some secret weapons project that was much more sensitive than the V-1 and V-2, and that still required redaction even many decades later. Based on the sorts of projects that Germany appears to have been conducting, and the sorts of projects that would provoke such secrecy from U.S. officers and censors, it seems almost certain that Redaction 4 concerned the German nuclear weapons program. There are several plausible wordings that match the 16-character space, including "_the_Tube_Alloy_", "_the_German_T_A_", "_an_atomic_bomb_", "_SS_atomic_bomb_", or "_atomic_weapons_".

Redaction 5 contained 18 characters between the beginning of the line and the apparent location of the period, including any spaces. It seems to have named the headquarters and/or the most important production location for the German nuclear weapons program. As such, this information would be of great interest to modern investigators. The 18-character location name is preceded by "the", which also helps to narrow down the possible answers. "BERGKRISTALL_plant" (St. Georgen/Gusen) and "Truppenübungsplatz" (Ohrdruf) are plausible answers. Other possible locations might have included Linz, Pilsen, Prague, Tuchola Forest/Tucheler Heide, etc., although it is challenging to think of names that the U.S. military would have used for those locations and that would have been preceded by "the" and had 18 characters.

Redaction 6 contained 21 characters between "of" and the apparent location of the period, including any spaces. It named the military unit to which Kammler surrendered, and it was probably redacted to prevent investigators from verifying this document and finding related documents. Based on U.S. troop movements and locations in early May 1945, a plausible answer is "_4th_Armored_Division".

Redaction 7 contained 17–19 characters, and most likely 18 characters based on how far the other black marks protrude beyond the edge of a redacted word. Redaction 7 was the second in a list of four items. The first and third items were almost exactly as named earlier in the memorandum, so the redacted phrase was probably the same or nearly the same as named in Redaction 4. Some possibilities include "Tube_Alloy_project" (18 characters), "German_T_A_project" (18 characters), "German_TA_project" (17 characters), "Atomic_development" (18 characters), "SS_atomic_research" (18 characters), "SS_atomic_weapons" (17 characters), "Atomic_bomb_project" (19 characters), etc.

Redaction 8 was the person who wrote this memorandum. Once again, it was apparently redacted to prevent investigators from locating the source of the document, verifying its authenticity, and finding other related documents.

Can the archival source of this document be identified, and can unredacted versions of this document, the documents it mentions, and other related documents be released?]

[redacted]

Figure D.939: 7 May 1945 memorandum, proving that Hans Kammler was alive and being interrogated by the United States as of 7 May 1945 [courtesy of Rainer Karlsch; published in Reuter et al. 2019, p. 168].

Frederick I. Ordway III and Mitchell Sharpe. 1979. *The Rocket Team.* pp. 282–283.

On the same day that the first ship left [22 May 1945], Staver learned the exact location of the documents hidden by Huzel and Tessmann on April 3. He did so by a clever ruse. A couple of days earlier, talking with Fleischer in Bleicherode, he casually pulled a notebook from his pocket and read an imaginary entry:

> Von Braun, Steinhoff, and all the others who fled south have been interned at Garmisch. Our intelligence officers have talked to von Ploetz [Kammler's intelligence officer], General Dornberger, General Rossmann, and General Kammler. They told us that many of your important drawings and documents were buried underground in a mine somewhere around here, and that you, Fleischer, could help us find them.

As he finished, he watched the German closely. Fleischer was upset by what he had heard and reacted visibly. Staver, not wanting to appear overly eager to find the cache of documents, merely told him to think things over and that he would see him the next day. [...]

Fleischer and Rees finally located the mine[...] Then they returned to Nordhausen to inform Staver, arriving there at 1:30 AM on May 22.

[Wernher von Braun and other key German rocket experts provided direct input for this book, which covered the work by those experts in Germany during the war and in the United States after the war. The book was published in 1979, a couple of years after von Braun's death.

According to this book, U.S. Army Major Robert B. Staver told a false story to a German, Karl Otto Fleischer, in order to persuade him to reveal where some rocket documents had been buried. The allegedly false story was that under interrogation by U.S. intelligence officers, Hans Kammler had said that Fleischer knew where the documents were. Even if it was false that Fleischer had been implicated during the interrogation of Kammler, it was in fact true that Kammler was in the custody of U.S. intelligence officers and was being interrogated at that time.

According to official accounts, which presumably would have been widely reported both in these German circles and in U.S. military circles since Kammler was such a high-ranking figure, Kammler had been killed or committed suicide in early May. Staver's bluff suggests that both Staver and Fleischer knew that Kammler was in fact alive and in U.S. custody; otherwise the bluff would not have been credible.

Perhaps it was not even a bluff at all. Maybe Kammler really did discuss the buried documents during his interrogation, and Staver was simply using an actual fact as leverage to persuade Fleischer to reveal where the documents were hidden. In order to maintain the official story that Kammler died in early May 1945, Staver's claim to Fleischer may have later been explained away as fictional.]

James McGovern. 1964. *Crossbow and Overcast.* pp. 167–169.

On the afternoon of May 18, a plane arrived from Brunswick with Drs. [Victor H.] Fraenckel and [Howard P.] Robertson, two civilian technical investigators attached to General Eisenhower's headquarters. [...]

Dr. Robertson agreed with Staver's view, then glanced through his pocket notebook and read a notation: "Von Ploetz said that General Dornberger told General Rossmann that documents of V-weapon production were hidden in *Kaliwerke* (salt mine) at Bleicherode, walled into one of the mine shafts. Von Ploetz was G-2 [intelligence] to Kammler." Dr. Robertson suggested that Rees or Fleischer might be able to direct Major Staver to the salt mine in question, but other than that Dr. Robertson had no further information to offer.

Major Staver spent the rest of the afternoon interrogating Walther Riedel with the thought constantly in the back of his mind of how to turn Dr. Robertson's sketchy lead to the best advantage. The V-2 documents, of course, were not in the salt mine at Bleicherode, which contained only some minor material relating to production. At 6 P.M., Staver left the U.S. Military Government building with Riedel and found that Fleischer had been waiting for them in his two-seater roadster. As casually as he could, after a few words of greeting with Fleischer, Staver took out his own pocket notebook and read from it: "Von Braun, Steinhoff, and all of the others who fled to the south have been interned at Garmisch. Our intelligence officers have talked to von Ploetz, General Dornberger, General Rossmann, and General Kammler. They told us that many of your drawings and important documents were buried underground in a mine somewhere around here, and that Riedel, or *you*, Fleischer, could help us find them."

This was, of course, a fabrication designed to make Fleischer and Riedel think they had been put on the spot by their superiors. Staver reasoned that if they did have any knowledge of a cache of documents they would believe either that they had to tell him where it was or risk being imprisoned for withholding information their superiors wanted the Americans to have.

[James McGovern gave an independent account of the same incident and added a few details. In particular, he mentioned the involvement of Dr. Howard P. Robertson and Dr. Victor H. Fraenckel. Robertson was the head and Fraenckel was a member of the Scientific Intelligence Advisory Section (SIAS) at the Supreme Headquarters Allied Expeditionary Force (SHAEF). Thus they were scientific advisors of the highest level for Dwight Eisenhower. Their direct personal involvement out in the field suggests that this was a matter of the greatest impossible importance. Robertson and Frankel seem to have been involved in interrogating Hans Kammler's intelligence chief, von Ploetz. Could they also have been involved in interrogating Kammler?

What information and archival documents can be located regarding the wartime work and postwar interrogations of von Ploetz? As Kammler's intelligence chief, he would have known a great deal about the most secret German weapons programs.

Sp. It was difficult to procure the necessary amount of Oxygen, because I already had difficulties to get oxygen for industrial purposes. I found reasons against the expansion of this program. The bottleneck here was the electro-industry on one side, and oxygen on the other.

Q. We know that one of the most typical features of all V-programs is the fact that they required high temperature, high pressure etc. That means that they required high-grade steel. How would the load on steel have been in the case of a planned expansion of the program?

Sp. I had refused to produce more than 600 a month. Originally 900 were planned. I had also refused to carry out an initial expansion of the anti-aircraft rocket. Isaid that when the anti-aircraft rocket comes, V-2 will have to step back and its capacity used for the anti-aircraft rocket, because it was too great a luxury for me. I could have made about 5 to 6 Fighters with the same man power as the V-2 took, which would have been better from my point of view. It is a technical experience to see such a rocket, piloted by a ray from below, going into the air, electrically directed. That is technically the most advanced thing one can imagine.

Q. Didn't about half of the projectiles explode before they got away?

Sp. There was the danger that the projectile would not take off straight. Then one could observe the steering, how the projectile was always brought back into the right direction again.

Q. Do you have figures about how high the losses were at the launching?

Sp. Kammler must be able to tell you exactly about this. As far as I know, a projectile came back 10 or 12 times. But then there is none left in the neighborhood, except the command tank with the two people who guide the projectile. It happened that the fusing of the explosive charge did not immediately take effect, but only a few minutes later, so that this last service crew also could get away. The worst thing was when the projectile could not be brought into the right direction, coming down approximately 30 kilometers from the launching site.

Q. Do you assume in your estimate that the production of the V-weapon injured English production more than German?

Sp. More than German. I have often said that. For one thing because the dispersal was so great that no real effect could be obtained. I considered the nerves of the Englishmen to be so good that they would stick it out anyway. And your victories came first. A victorious nation could not be impressed by that. I believe however, that the development of the V-2 will definitely be the most important factor for war in later times. At the present time it did not come to full effectiveness. It can be launched from a ship, from every street. They do not need a previously prepared launching site and in the course of time their striking accuracy will be just as great as with bombing.

CONFIDENTIAL

HEADQUARTERS
UNITED STATES STRATEGIC AIR FORCES IN EUROPE
Office of Asst. Chief of Staff A-2
Exploitation Division, Operations Section

A 2

30 May, 1945

MEMORANDUM: Summary of Activities, Operations Section, Exploitation Division.

TO : Colonel Sheldon.

To date the intelligence exploitation of the German Air Force and of German technical facilities has yielded a vast amount of materiel and documents. Briefly to evaluate at this time the worth of such materiel and documents is made difficult due to the fact that the emphasis has necessarily been upon the speed of collection rather than upon concise evaluation. However enough progress has already been made to indicate that approximately half of the category "one" items assigned for evacuation by Wright Field have been secured. Much of the materiel for the longer term research into all aspects of the German Air Force as required by "Air Staff Post Hostilities Intelligence Requirements" prepared by AC/AS, Intelligence, Hq, AAF, is presently being gathered.

There follows a brief outline of recapitulation of the accomplishments to date divided into technical and non-technical exploitation.

AIRCRAFT DESIGN AND GENERAL AERODYNAMICS

1. FOCKE-WULFE-190, 2 long-nosed versions having two-stage superchargers, and possessing Gyro-stabilized compensating gun sights being crated at KASSEL for shipment~~, to ATSC, Wright Field.~~

2. DORNIER-335, tandem engine, multipurpose aircraft. One specimen found, damaged and not flyable, being crated at KASSEL, for shipment, ~~to ATSC, Wright Field~~.

3. JUNKER-388, High altitude, reconnaissance twin engine (BMW 901-TJ03), in perfect flying condition is now at A-42, Paris. This outstanding completed aircraft possesses:

a. Pressurized cabin.

b. Two stage mechanical blower in addition to exhaust driven supercharged engines. Ample gasoline supply of 1017 gallons for long range reconnaissance and complete instrumentation including auto-pilot, radar search, terrain altimeter, and homing service.

4. MESSERSCHMITT series 1101, 1106, 1110, 1111 and 1112 Fighter Jet Athodyd (Lorin) Propelled Aircraft. This series of airplanes is extremely interesting in that it illustrates a phase of coordinated aircraft design into which the American industry is now entering. This series of aircraft represent an effort on the part of the Messerschmitt plant to develop an extremely high-performance single seat fighter by means of carefully tailoring the power unit, a very simple ram-compressor type jet unit, directly into the aircraft structure. The difficulties met by the Messerschmitt research development program in the form of optimum cockpit location, methods

SECRET

of air induction, location of discharge openings and control technique were recorded by Messerschmitt and are in our possession. The series of models produced and tested by the Messerschmitt plant presents complete information upon how to overcome the individual difficulties mentioned above. This information is contained in a report prepared by Mr. Puffer of the General Electric Co., and is being prepared for distribution.

5. HORTEN-229, Twin Jet Jumo 004 engines, flying wing, now located at HANAU. One complete fuselage, a nearly complete set of wings and another incomplete fuselage are being crated and are being shipped to ATSC, Wright Field.

6. HELICOPTER, jet propelled aircraft in flyable condition has been captured near Stuttgart. Complete documents and detailed drawings for construction have been captured and the aircraft is being air-freighted to KASSEL for shipment in overseas transport.

7. JU-290, 4 engine large transport as large as the B29 and capable of being converted to a bomber has been captured at MUNICH. This aircraft is being prepared for carrier overseas transport.

8. JU-88 G6, radar equipped night fighter, twin engined, being prepared for carrier overseas transport.

9. ME-262, ten on hand of miscellaneous types, all fighter intercepter, twin-jet propelled, being flown to aircraft carrier for overseas transport. One shipped by fast boat to United States on May 9.

10. HORTON-9, Flying Wing Glider is available at KASSEL. This aircraft is being crated for shipment to ATSC, Wright Field.

11. ME-163, Rocket propelled intercepter fighter. Seven of these aircraft most of which are new and have never been flown are being crated at KASSEL for shipment to the United States. Arrangements are being made for C-54 air shipment for one of these aircraft to ATSC, Wright Field. One glider version of this aircraft is being crated at KASSEL for shipment to the United States in addition to the powered models.

12. HE-162, single place fighter, powered by a Jumo 003 jet engine. Four of these are being crated at KASSEL for shipment to ATSC, Wright Field.

13. ARADO-234, powered by two Jumo 004 engines. Two of these aircraft have been allocated to AAF by the British and will be taken to KASSEL for crating and shipment to the United States.

14. FLETTNER-282 Helicopter. One of these aircraft is being shipped to KASSEL for crating and shipment to ATSC, Wright Field.

15. TA-152, Long-nosed Focke-Wulfe with pressurized cabin. Possesses the in-line engine and is capable of high altitude intercepter operation.

16. JU-248 aircraft, rocket propelled, similar to the ME-163 being prepared for shipment to ATSC, Wright Field.

SECRET

17. FLYING BOMBS, Single Pilot, type V-1. Eight on hand and one being prepared for priority 1 air shipment to ATSC, Wright Field.

18. FLYING BOMBS, dual piloted type. Two are available and being prepared for carrier shipment to ATSC, Wright Field.

19. LIPPISCH P-13 JAGER, tailless twin rocket propelled wing for supersonic speeds indicate that this flying wing together with the unique aircraft controls indicate possible operation at high mach numbers in the vicinity of .85. One aircraft is being assembled in the vicinity of KOECHEL, AUSTRIA and will be available for shipment to ATSC, Wright Field. The air foil section of the sweep back wing is a symmetrical laminar-flow design with a minimum of parasite resistance. The cockpit is located about midway up the dorsal fin, thus allowing the twin rocket tubes of the Lorin type engine to be installed outboard of the center section and completely contained within the wing contour. Evidence indicates that this aircraft design may be capable of supersonic speeds and that high speeds would initially be reached by the employment of assisted takeoff accelerating rocket units to gain a speed of approximately 80 meters per second.

AIRCRAFT JET ENGINES

20. Athodyd (Lorin Engines) units developing thrusts in excess of 1500 kilograms have been uncovered and sufficient design data is in our possession to permit immediate application in the field of high speed aircraft production at ATSC, Wright Field.

21. Arrangements have been made to run a series of performance tests in the high-altitude engine test beds of the BMW outfit at Munich. It is contemplated that several HIRTH 011, BMW 003 and JUNKERS 004 jets of various series, some supposedly running well over 3000 pounds in thrust will be tested during these trials. This test bed equipment appears to be the most elaborate in the world being capable of supplying refrigerated low-pressure air both for engine cooling and combustion, thus completely simulating atmospheric conditions at approximately 40,000 feet.

22. Plans and specifications have been recovered for a number of experimental jet and turbine engines developing extremely high thrusts, and in some cases making use of conventional propeller drive as a means of reducing excessive fuel consumption rates at low altitudes. Included in this series is the BMW 028 delivering an imput of 9,000 H.P. through its propeller unit while operating under thrust of an equivalent of 3,000 H.P. of direct Jet discharge. The JUNKERS 022 is another propeller and turbine combination, however complete drawings and plans are not yet available.

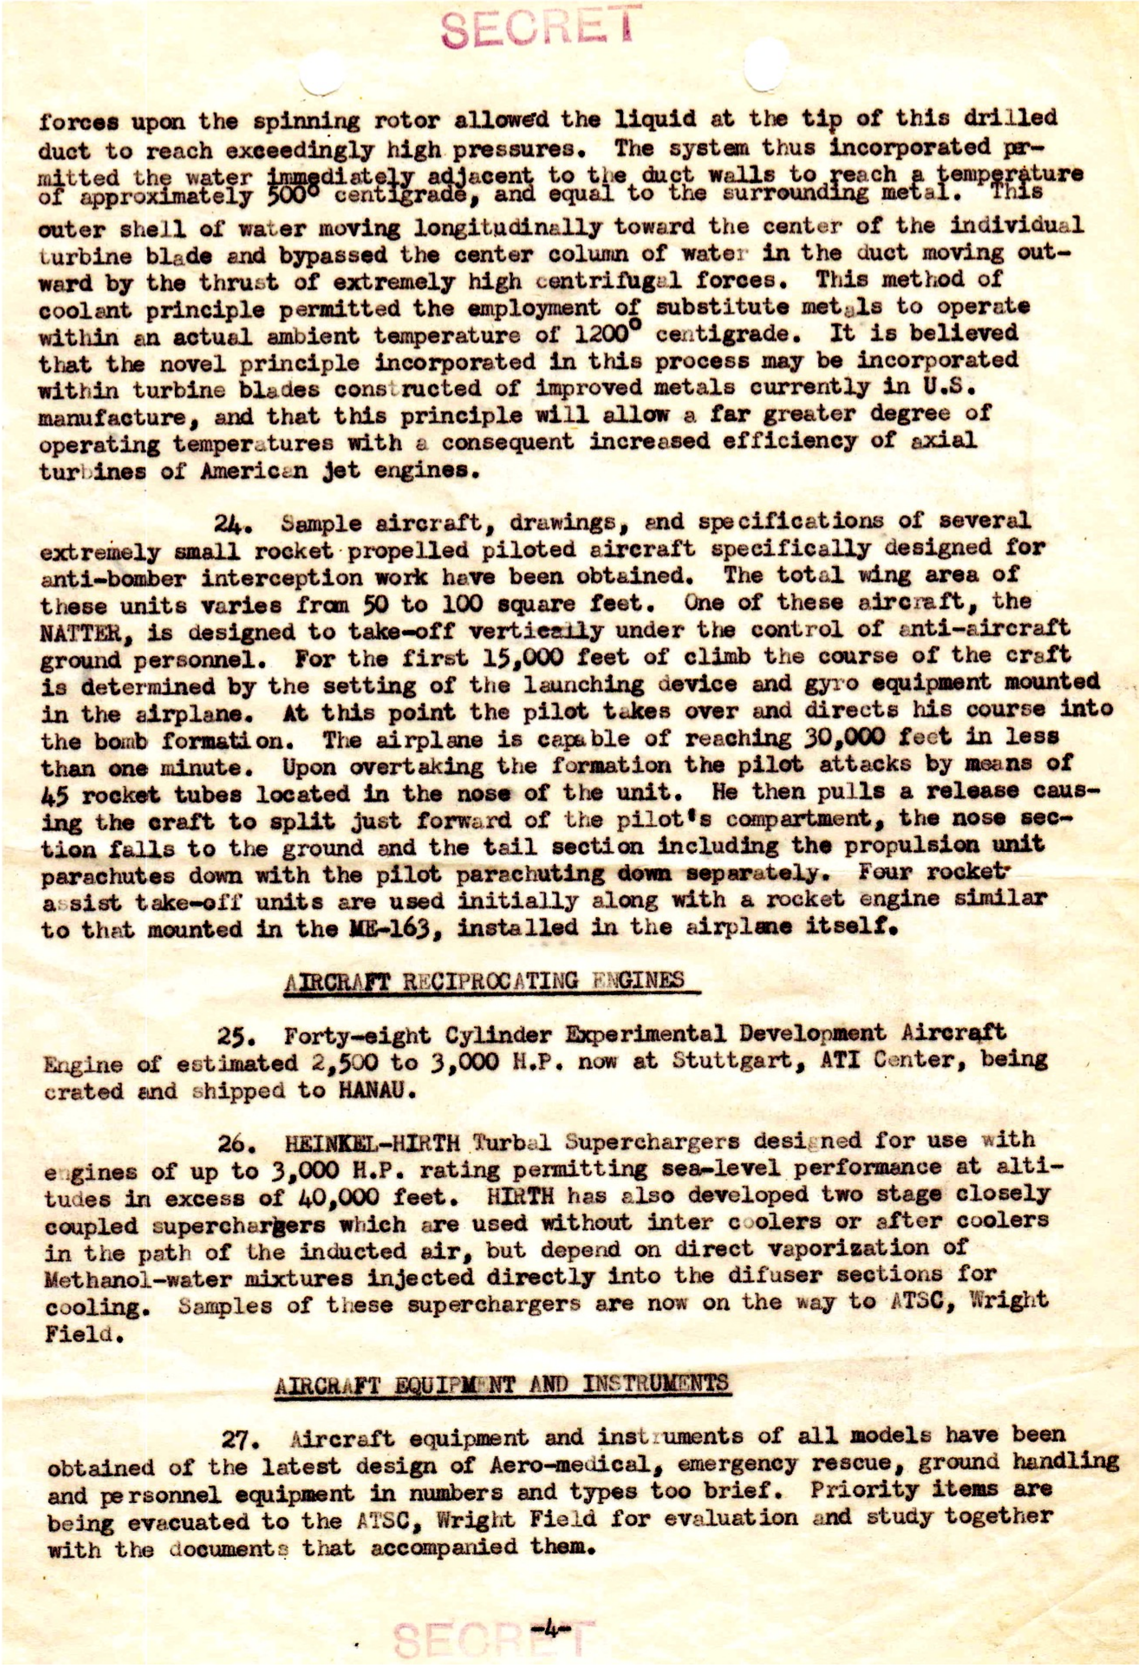
23. Convection Steam Cooling. The use of substitute metal for engine turbine blades in lieu of high tensil strength alloy metals that had been available to allied nations, but which were not available to Germany, presented a problem to German research which was met in a novel experimental development. The individual blade was provided with a circulating liquid system within each blade. By the incorporation of a drilled duct through the center of the blade, and filling this cylinder with water, centrifugal

-3-

SECRET

Figure D.944: 30 May 1945 memorandum from Colonel Loyd K. Pepple to Colonel Sheldon, proving that Hans Kammler was alive and being interrogated by the United States as of 30 May 1945 [AFHRA folder 570.605 1944–46, Misc. Documents G-2 Miscellaneous Data].

AFHRA folder 570.605 1944–46, Misc. Documents G-2 Miscellaneous Data



SECRET

forces upon the spinning rotor allowed the liquid at the tip of this drilled duct to reach exceedingly high pressures. The system thus incorporated prmitted the water immediately adjacent to the duct walls to reach a temperature of approximately 500° centigrade, and equal to the surrounding metal. This outer shell of water moving longitudinally toward the center of the individual turbine blade and bypassed the center column of water in the duct moving outward by the thrust of extremely high centrifugal forces. This method of coolant principle permitted the employment of substitute metals to operate within an actual ambient temperature of 1200° centigrade. It is believed that the novel principle incorporated in this process may be incorporated within turbine blades constructed of improved metals currently in U.S. manufacture, and that this principle will allow a far greater degree of operating temperatures with a consequent increased efficiency of axial turbines of American jet engines.

24. Sample aircraft, drawings, and specifications of several extremely small rocket propelled piloted aircraft specifically designed for anti-bomber interception work have been obtained. The total wing area of these units varies from 50 to 100 square feet. One of these aircraft, the NATTER, is designed to take-off vertically under the control of anti-aircraft ground personnel. For the first 15,000 feet of climb the course of the craft is determined by the setting of the launching device and gyro equipment mounted in the airplane. At this point the pilot takes over and directs his course into the bomb formation. The airplane is capable of reaching 30,000 feet in less than one minute. Upon overtaking the formation the pilot attacks by means of 45 rocket tubes located in the nose of the unit. He then pulls a release causing the craft to split just forward of the pilot's compartment, the nose section falls to the ground and the tail section including the propulsion unit parachutes down with the pilot parachuting down separately. Four rocket assist take-off units are used initially along with a rocket engine similar to that mounted in the ME-163, installed in the airplane itself.

AIRCRAFT RECIPROCATING ENGINES

25. Forty-eight Cylinder Experimental Development Aircraft Engine of estimated 2,500 to 3,000 H.P. now at Stuttgart, ATI Center, being crated and shipped to HANAU.

26. HEINKEL-HIRTH Turbal Superchargers designed for use with engines of up to 3,000 H.P. rating permitting sea-level performance at altitudes in excess of 40,000 feet. HIRTH has also developed two stage closely coupled superchargers which are used without inter coolers or after coolers in the path of the inducted air, but depend on direct vaporization of Methanol-water mixtures injected directly into the difuser sections for cooling. Samples of these superchargers are now on the way to ATSC, Wright Field.

AIRCRAFT EQUIPMENT AND INSTRUMENTS

27. Aircraft equipment and instruments of all models have been obtained of the latest design of Aero-medical, emergency rescue, ground handling and personnel equipment in numbers and types too brief. Priority items are being evacuated to the ATSC, Wright Field for evaluation and study together with the documents that accompanied them.

SECRET

ELECTRONICS

28. Extensive investigation of the German Air Ministry Files located at KOETHEN disclose very complete information on the operation and the installation of the German Radar equipment, JOGDSCHLOSS. The JOGDSCHLOSS is a long range early warning radar equipment used by the Germans for the detection of enemy aircraft. Complete reports on this equipment are being prepared by the Electronics Intelligence Section and will be forwarded to the interested agencies.

29. Complete information on the FREYA and RIESE "G" Wurtzburg radar equipment has been uncovered at the research laboratory located at KOETHEN. This equipment was used by the Germans for ground control interception of enemy aircraft and at present is being classified and crated for shipment to ATSC, Wright Field.

30. A complete establishment of allied radar equipment was discovered at the KOETHEN laboratory. This allied equipment was used for research by the Germans, to determine the various characteristics of equipment of the Allied Nations. It also aided in determining the effectiveness of German counter measures against Allied equipment and in instructing German students in operation technique.

31. Three complete assemblies of the FX-1400 Radio controlled bomb are being sent to the ATSC, Wright Field. In addition, three tail assemblies which contain the radio control are also being shipped to the Aircraft Radio Laboratory, Wright Field, Ohio. This equipment is similar to the AAF Azon.

32. The Telefunken Corporation in Germany, under Dr. Brandt, Chief of Development Research, have trained 2,200 Japanese in radar and infrared technique.

DIRECTED MISSILES

33. X-4 ROCKET. A specimen of the German secret weapon X-4 rocket propelled, winged, controlled anti-aircraft missile, has been found and returned to the Air Ministry AI-2(g), for complete examination.

34. This missile is intended for launching from German fighter aircraft against U.S. heavy bombardment daylight formations and is controlled from the fighter aircraft by means of a pair of thin wires. Experimental development had not been completed, and no known flight testing of the X-4 missile has ever been recorded.

35. HS-117. An anti-aircraft missile launched from the ground has been found and sent to Air Ministry AI-2 (g) for examination. The item was incomplete but examination indicates that it was capable of being launched from fighter aircraft and by means of a development proximity fuse, to be detonated in the midst of a heavy bombardment formation.

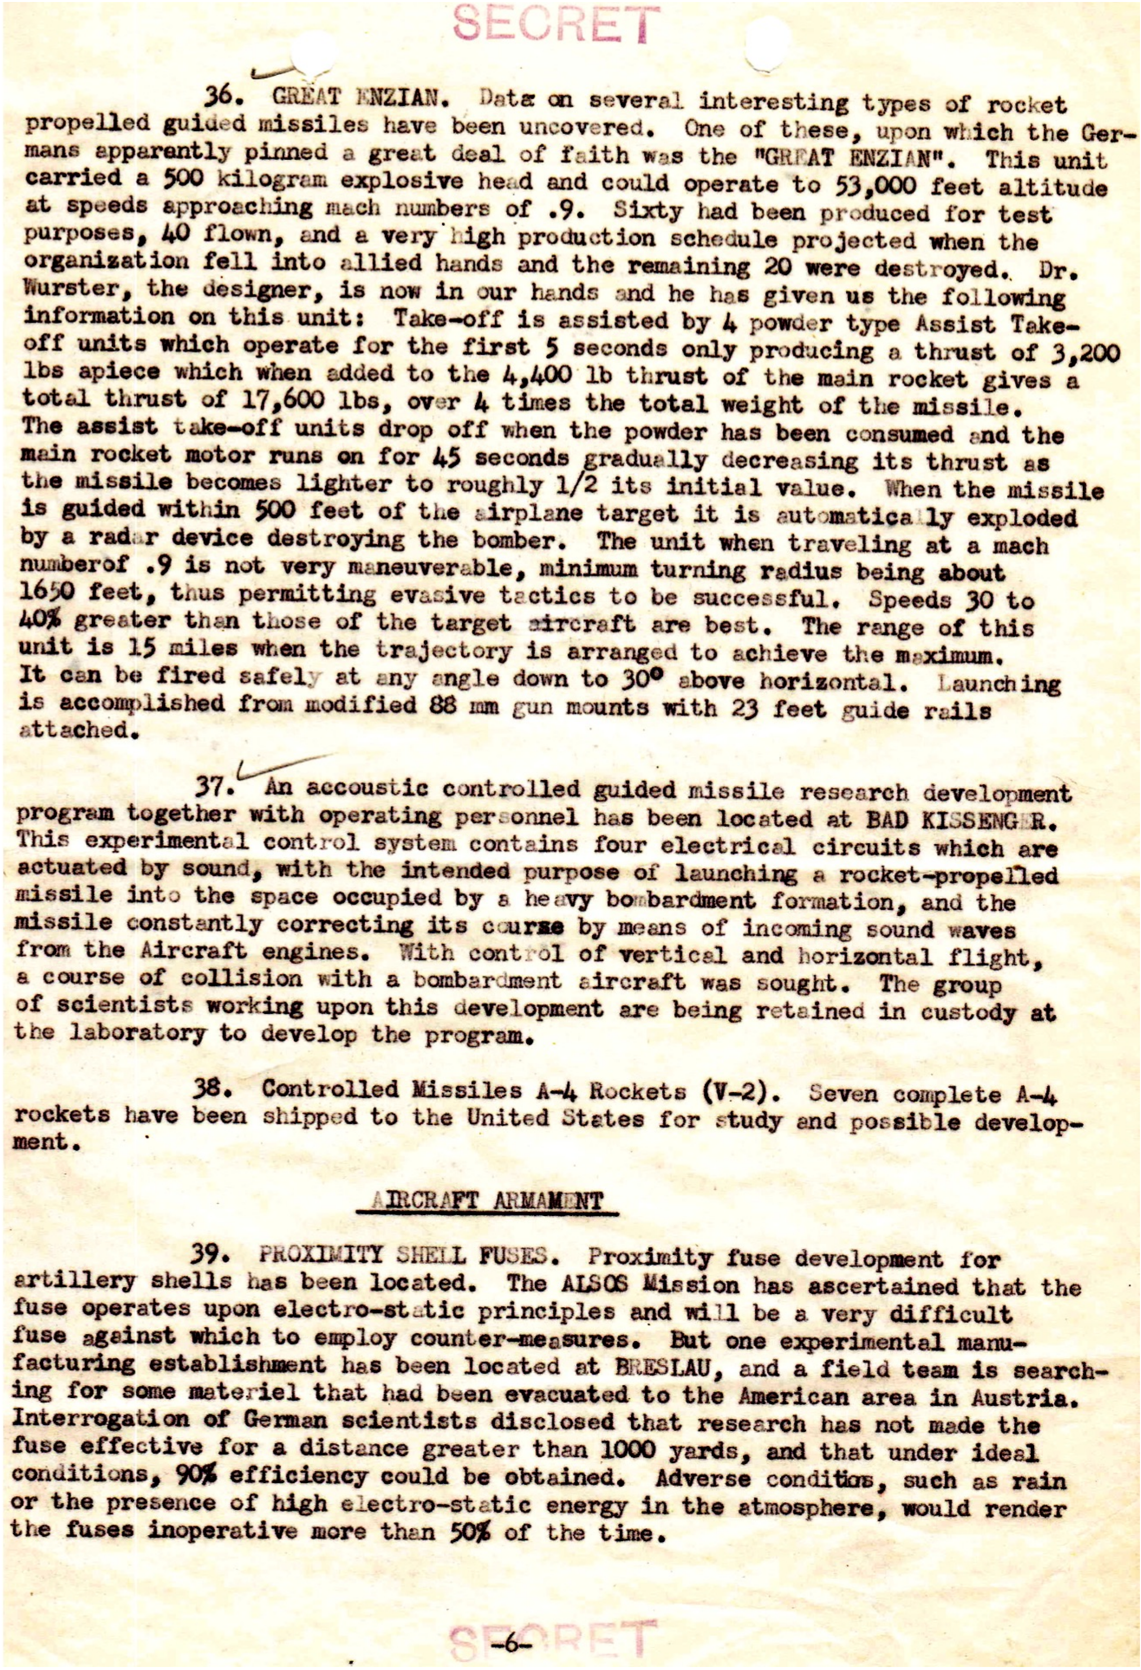
SECRET

Figure D.946: 30 May 1945 memorandum from Colonel Loyd K. Pepple to Colonel Sheldon, proving that Hans Kammler was alive and being interrogated by the United States as of 30 May 1945 [AFHRA folder 570.605 1944–46, Misc. Documents G-2 Miscellaneous Data].

AFHRA folder 570.605 1944–46, Misc. Documents G-2 Miscellaneous Data



SECRET

36. GREAT ENZIAN. Data on several interesting types of rocket propelled guided missiles have been uncovered. One of these, upon which the Germans apparently pinned a great deal of faith was the "GREAT ENZIAN". This unit carried a 500 kilogram explosive head and could operate to 53,000 feet altitude at speeds approaching mach numbers of .9. Sixty had been produced for test purposes, 40 flown, and a very high production schedule projected when the organization fell into allied hands and the remaining 20 were destroyed. Dr. Wurster, the designer, is now in our hands and he has given us the following information on this unit: Take-off is assisted by 4 powder type Assist Take-off units which operate for the first 5 seconds only producing a thrust of 3,200 lbs apiece which when added to the 4,400 lb thrust of the main rocket gives a total thrust of 17,600 lbs, over 4 times the total weight of the missile. The assist take-off units drop off when the powder has been consumed and the main rocket motor runs on for 45 seconds gradually decreasing its thrust as the missile becomes lighter to roughly 1/2 its initial value. When the missile is guided within 500 feet of the airplane target it is automatically exploded by a radar device destroying the bomber. The unit when traveling at a mach numberof .9 is not very maneuverable, minimum turning radius being about 1650 feet, thus permitting evasive tactics to be successful. Speeds 30 to 40% greater than those of the target aircraft are best. The range of this unit is 15 miles when the trajectory is arranged to achieve the maximum. It can be fired safely at any angle down to 30° above horizontal. Launching is accomplished from modified 88 mm gun mounts with 23 feet guide rails attached.

37. An accoustic controlled guided missile research development program together with operating personnel has been located at BAD KISSENGER. This experimental control system contains four electrical circuits which are actuated by sound, with the intended purpose of launching a rocket-propelled missile into the space occupied by a heavy bombardment formation, and the missile constantly correcting its course by means of incoming sound waves from the Aircraft engines. With control of vertical and horizontal flight, a course of collision with a bombardment aircraft was sought. The group of scientists working upon this development are being retained in custody at the laboratory to develop the program.

38. Controlled Missiles A-4 Rockets (V-2). Seven complete A-4 rockets have been shipped to the United States for study and possible development.

AIRCRAFT ARMAMENT

39. PROXIMITY SHELL FUSES. Proximity fuse development for artillery shells has been located. The ALSOS Mission has ascertained that the fuse operates upon electro-static principles and will be a very difficult fuse against which to employ counter-measures. But one experimental manufacturing establishment has been located at BRESLAU, and a field team is searching for some materiel that had been evacuated to the American area in Austria. Interrogation of German scientists disclosed that research has not made the fuse effective for a distance greater than 1000 yards, and that under ideal conditions, 90% efficiency could be obtained. Adverse conditions, such as rain or the presence of high electro-static energy in the atmosphere, would render the fuses inoperative more than 50% of the time.

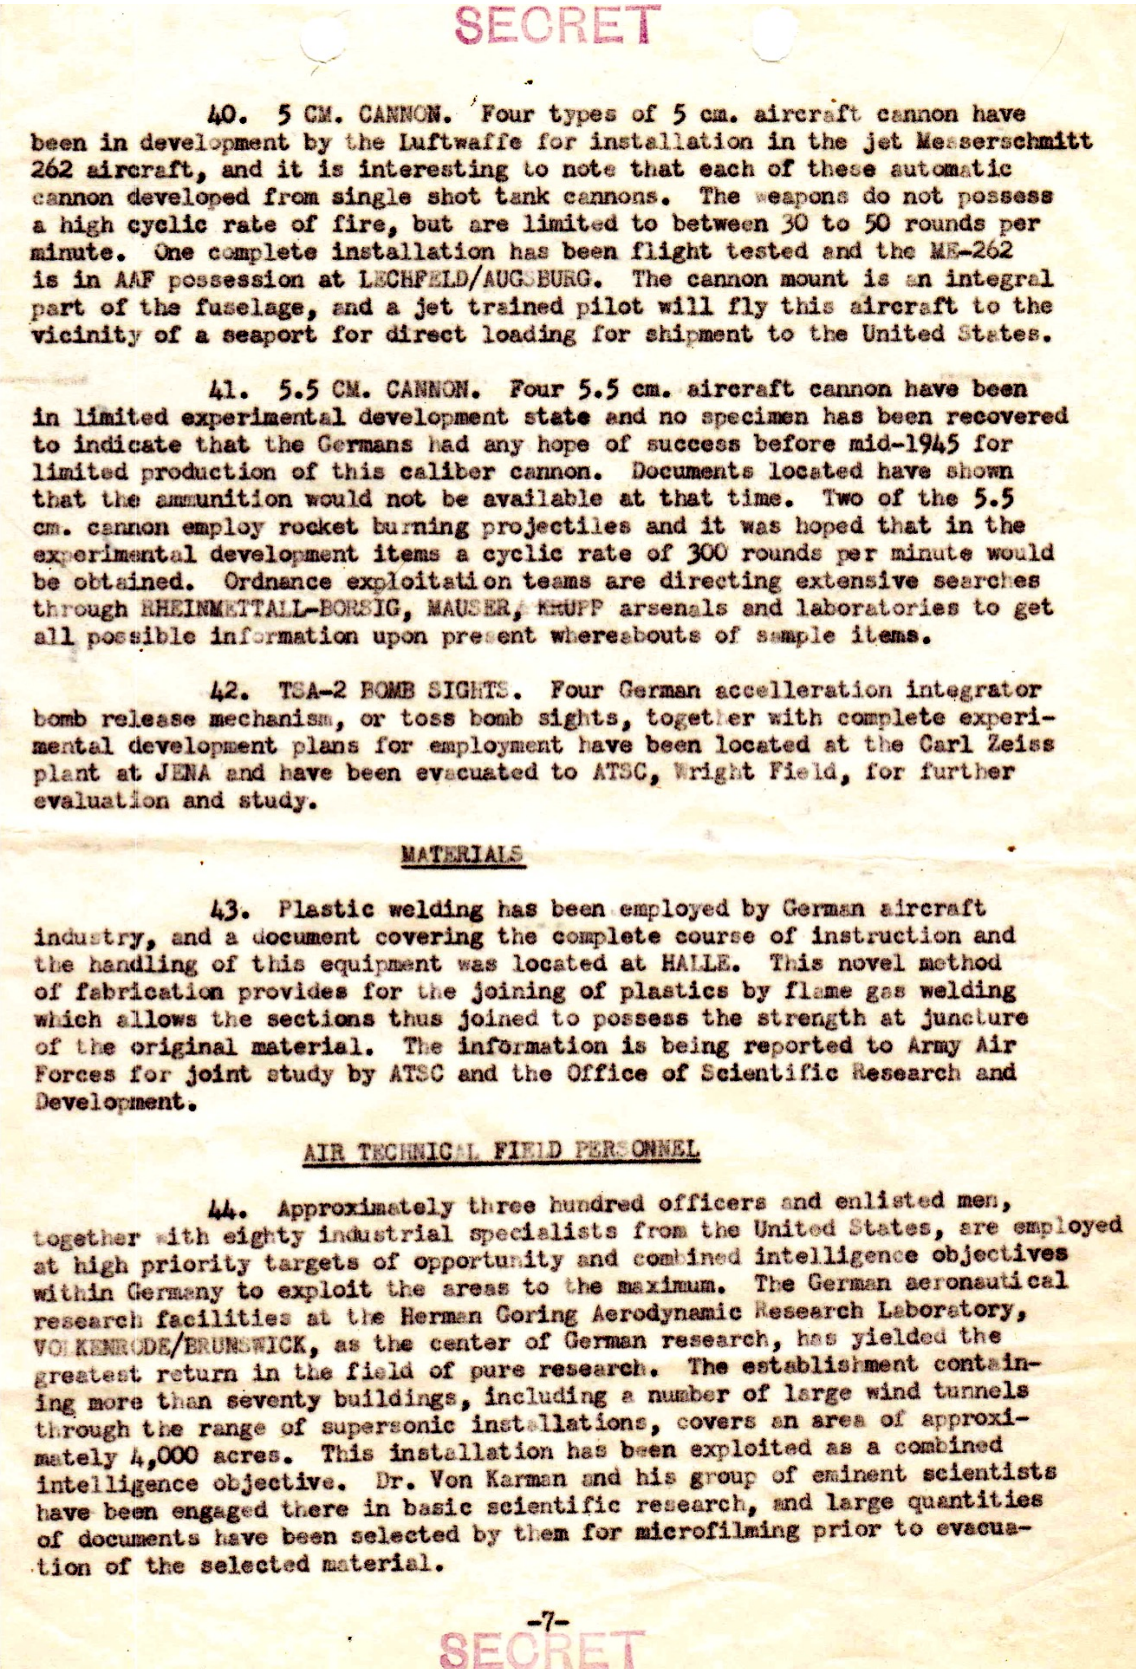
Figure D.947: 30 May 1945 memorandum from Colonel Loyd K. Pepple to Colonel Sheldon, proving that Hans Kammler was alive and being interrogated by the United States as of 30 May 1945 [AFHRA folder 570.605 1944–46, Misc. Documents G-2 Miscellaneous Data].

AFHRA folder 570.605 1944–46, Misc. Documents G-2 Miscellaneous Data



SECRET

40. 5 CM. CANNON. Four types of 5 cm. aircraft cannon have been in development by the Luftwaffe for installation in the jet Messerschmitt 262 aircraft, and it is interesting to note that each of these automatic cannon developed from single shot tank cannons. The weapons do not possess a high cyclic rate of fire, but are limited to between 30 to 50 rounds per minute. One complete installation has been flight tested and the ME-262 is in AAF possession at LECHFELD/AUGSBURG. The cannon mount is an integral part of the fuselage, and a jet trained pilot will fly this aircraft to the vicinity of a seaport for direct loading for shipment to the United States.

41. 5.5 CM. CANNON. Four 5.5 cm. aircraft cannon have been in limited experimental development state and no specimen has been recovered to indicate that the Germans had any hope of success before mid-1945 for limited production of this caliber cannon. Documents located have shown that the ammunition would not be available at that time. Two of the 5.5 cm. cannon employ rocket burning projectiles and it was hoped that in the experimental development items a cyclic rate of 300 rounds per minute would be obtained. Ordnance exploitation teams are directing extensive searches through RHEINMETTALL-BORSIG, MAUSER, KRUPF arsenals and laboratories to get all possible information upon present whereabouts of sample items.

42. TSA-2 BOMB SIGHTS. Four German accelleration integrator bomb release mechanism, or toss bomb sights, together with complete experimental development plans for employment have been located at the Carl Zeiss plant at JENA and have been evacuated to ATSC, Wright Field, for further evaluation and study.

MATERIALS

43. Plastic welding has been employed by German aircraft industry, and a document covering the complete course of instruction and the handling of this equipment was located at HALLE. This novel method of fabrication provides for the joining of plastics by flame gas welding which allows the sections thus joined to possess the strength at juncture of the original material. The information is being reported to Army Air Forces for joint study by ATSC and the Office of Scientific Research and Development.

AIR TECHNICAL FIELD PERSONNEL

44. Approximately three hundred officers and enlisted men, together with eighty industrial specialists from the United States, are employed at high priority targets of opportunity and combined intelligence objectives within Germany to exploit the areas to the maximum. The German aeronautical research facilities at the Herman Goring Aerodynamic Research Laboratory, VOLKENRODE/BRUNSWICK, as the center of German research, has yielded the greatest return in the field of pure research. The establishment containing more than seventy buildings, including a number of large wind tunnels through the range of supersonic installations, covers an area of approximately 4,000 acres. This installation has been exploited as a combined intelligence objective. Dr. Von Karman and his group of eminent scientists have been engaged there in basic scientific research, and large quantities of documents have been selected by them for microfilming prior to evacuation of the selected material.

SECRET

45. Kockel Research Center. Approximately 700 German research specialists evacuated from the Peenemunde area are engaged in research under their original director, Dr. Herman. Included in the equipment are 3 supersonic tunnels, in good working order, with experiments being conducted in the field of aerodynamic research.

GERMAN SCIENTIFIC PERSONNEL

46. Eminent scientific personnel are available for interrogation concerning German Air Force activities in all the fields of scientific and industrial research. The following are a list of the key personnel together with their principal related activity.

Dr. Ing. Johann W.T. Cassens	Chief Static & Vibration Test Section.
Dr. Helmut Wittmeyer	Asst. to Dr. Cassens-Vibration Specialist.
Wittwer	Chief, Photo Reproduction & Process Section.
Heintzeiman	Chief Stress Analysis Rigidity Section.
Walter Horten) Reimar Horten)	Brothers in firm "Horten Flugzeugbay G.m.b.H. BONN/Rh. and have Werkstaette at GOETTINGEN & HEPSFELD. Specialize in "nur Fluegel Flugzeuge"
Oberst Ing. Lorenz	Administrative link between development committee and GAF research establishments. A-1 ADI (K).
Oberst Hoeffner	Chief of Rlwy transport in France before and after invasion. Has left ADI (K). See Rept 301/45.
Oberst Trubenbach	JAFU Mittelrheim. With ADI (K).

NON-TECHNICAL INTELLIGENCE EXPLOITATION

48. GAF RELATIONS WITH JAPAN. Heinz Weber, official German Government interpreter on all German-Japanese negotiations relating to the Japanese air effort, evacuated to United States 15 May, 1945. Documents evacuated with Weber consisted of a basic document of thirty pages and six annexes, setting forth:

a. Japanese aircraft production, 1939-1945.

b. Japanese flak guns.

c. Japanese Navy aircraft as of 1 June, 1944.

d. Aircraft equipment manufacturing industry in Japan and Manchukuo.

e. Aircraft production darts for Japan as of 1 June, 1944.

f. Japanese Air armament industry and equipment as of 1 June, 1943.

49. GERMAN AIR EQUIPMENT SUPPLIED JAPAN. Documents concerning the supply of German war material to Japan have been recovered near Berchtesgaden. This file contains correspondence from 1 Gruppe/6 Abteilung, German Air Ministry Intelligence, dated from January, 1943 to March, 1945, concerning the supply of all types of equipment for aerial warfare, including models of the ME 262 and 163 (transported in a specially modified U-Boat), quantities of V-1 equipment, high explosive and incendiary bombs, bombsights, radar apparatus of all descriptions including models of the Wurzburg and Freya, radio and signals installations, telephones, teleprinters, etc., and all types of aircraft parts. In addition the following photographic equipment destined for Japan has been seized:

a. 25 Automatic aerial cameras Rb 20/30, complete

b. 60 Film magazines FK 30/60.

c. 6 Electric drives 24 V (Amot) with control box.

d. 6 view finders 18/1.

50. GAF MISSION TO JAPAN. Adjutant to head of GAF mission to Japan, Oberleutnant Schumann, seized with two other officers of mission, prior to their departure for Japan by submarine. Schumann's evacuation to United States was recommended. Other two officers not sufficiently knowledgeable to warrant evacuation. Technical drawings of German aircraft and engines for shipment to the Japanese Air Force with mission have been seized.

51. GAF INTELLIGENCE. The records of GAF Intelligence on the

Western Front contained in twenty-one boxes have been recovered in the Berchtesgaden area. Other leads for further files of GAF Intelligence are presently being exploited.

52. GAF PHOTOGRAPHIC INTELLIGENCE. GAF photographic coverage of England and the Continent was recovered at OKL Headquarters near Berchtesgaden in addition to a large stock of air maps dealing with European operations.

53. GAF "Y" (RADIO INTERCEPT) SERVICE. Exploitation teams indicate that stations of the GAF "Y" Service have been destroyed. A key civilian and other German PW are being interrogated on the "Y" Service and the civilian is engaged in writing a report on it.

54. GAF RECORDS. Administrative and supply records of the GAF are being recovered from their various hiding places in the Berchtesgaden area. The staff of OKL is being interrogated for further information regarding the location of additional records. Four hundred rolls of microfilm, purported to be the complete records of OKL, have been recovered from a salt mine near HILDESHEIM and are presently being examined. These files include:

a. Complete order of battle and strength reports of Germany's Western Air Fleet at the outbreak of this war.

b. Mobilization plans, pre-war maneuvers, and related reports.

c. Complete evaluated report of Legion Kondor (operational and administrative) during Spanish Civil War.

d. Loading records on troop and cargo aircraft from Italy and Africa.

e. Reports on traffic and cargo proceeding through Brenner Pass.

f. Complete organization and planning for the passive air defense of MUNICH and other Bavarian cities.

g. Complete bomb damage reports on MUNICH.

h. Numerous files, manuals, directives, hand books, etc., on the Luftwaffe and its administration.

55. SECRET WEAPONS. Records of the secret weapons program of the German Ministry of Production (Speer Ministry), contained in some forty boxes, have been seized and are being evacuated through air channels.

56. GAF RESEARCH REPORTS. Scientific reports evacuated from the German Academy of Aviation Research to a hiding place in Southern Germany have been recovered. These are in addition to eleven cases of scientific reports of other air research centers in Germany which have also been seized.

Ebensee and about S 2,400,000 were authorized for payment to creditors. Payment, however, was stopped and this accounts for the large balance. Had this sum been paid the balance would have been 1,100,000. On the other hand some additional 3,000,000 was forwarded to this account by the Reichsbank in München but the sum was not credited to the account because it was stopped by the Military authorities before it left München.

Shortly after the occupation, Hans Kammler appeared before the CIC in Gmünden and made a detailed statement on the operations and activities of the Baustelle Ebensee, as well as on the account, and his own authority and authority of Karl Englehardt. None of the presant American Officers at the CIC, Gmünden, is familiar with his statement but it should be in the files there. Mr. Morrison of the CIC, Gmünden was requested by the team to send a copy of this statement to Mr. Loehr.

CONCLUSIONS :

1. Sammelkonto was established by the Financial Division of the Military Government on 31 July 1945.

2. Sammelkonto received monies belonging to the German Wehrmacht and its affiliated organizations.

3. The details of the account show that some of the funds could not be classified as direct Wehrmacht funds without a more thorough investigation. ~~XX~~ There could be other funds which were erroneously classified as Wehrmacht funds.

~~4. Although the subsidiary organizations such as~~

Figure D.959: 2 November 1945 letter from General George C. McDonald to Major Ernst Englander, proving that Hans Kammler was alive and being interrogated by the United States as of November 1945 [AFHRA folder 570.6501A 1945–46, Special Projects—Current].

[By the end of the war, SS General (and Dr. Ing.) Hans Kammler controlled and knew the details of virtually all secret German weapons research and development. There are a number of reasons to believe that Kammler's authority and knowledge also included the nuclear program by the end of the war:

- In postwar interrogations, Skoda chief Wilhelm Voss stated that Kammler and his staff were in charge of the "most secret" weapons, including the atomic bomb (p. 4914).
- Heinrich Himmler's adjutant, Werner Grothmann, repeatedly said that Kammler was in charge of executing the nuclear program for Himmler and the SS, in direct association with Wilhelm Ohnesorge from the Reichspost [see for example pp. 3402 and 3865, and many other examples in Krotzky 2002].
- Surviving documents demonstrate that Kammler was indeed closely involved in technical discussions between Himmler at the SS and Ohnesorge at the Reichspost, and apparently directly responsible for implementing their programs (pp. 3385–3387).
- According to the 1962 interrogation of Heinz Wachsmut, written orders related to the March 1945 Thuringia nuclear test were signed by Hans Kammler, along with other SS and Reichspost offices (p. 4558).
- Kammler was in charge of all underground factories, including those where nuclear work apparently occurred, as well as the concentration camps that supplied the labor for those factories.
- Kammler was listed as a recipient for train shipments of supplies at the Gusen underground facility, alongside scientists such as the nuclear physicist Siegfried Flügge and the implosion bomb expert Hubert Schardin (p. 3882).
- Refugees from a nuclear facility in Lüneburger Heide seemed to indicate that Kammler was in charge of that and other similar facilities (p. 4180–4181).
- By the end of the war, Kammler controlled the potential delivery methods for nuclear weapons, including long-range rockets and jet aircraft.
- Kammler steadily amassed power over all types and aspects of advanced weapons development over the course of the war, apparently due to a combination of great political skill, extreme ambition, and ruthless efficiency. It would seem inevitable for the nuclear program to have eventually fallen under his control—he would not have let anything stop him.
- The documents on pp. 4931–4959 demonstrate that the United States concealed the fact that Kammler was alive after the war, shielded him from prosecution, and relied on his knowledge and assistance. Moreover, the United States has tried to keep that secret for 75+ years. Kammler must have offered the United States information that was especially useful—and especially damning—to have justified such extraordinary measures. Details of the German nuclear program would qualify as sufficiently important information.

The documents on pp. 4931–4959 prove that Kammler did not die in early May 1945, as was reported in various conflicting accounts, but rather that Kammler was alive, in U.S. custody, and available for interrogation at least as of November 1945. Apparently he surrendered to U.S. forces in early May, so he would have been in U.S. custody for approximately six months by the time of McDonald's memo, and perhaps for many more years afterward.

The U.S. government must possess lengthy transcripts or even audio/video recordings of Kammler's interrogations. It would also possess any documents and materials that Kammler had with him when he was captured, or that he was able to direct the Americans to afterward. Kammler's interrogations and documents would have provided the United States with considerable detail about the German nuclear program and other very advanced developments, such as the transcontinental rocket mentioned by Speer. (Albert Speer's own capture and interrogation, also referenced in McDonald's memo, resulted in many shelves full of documents.)

How can all of that Kammler material be located and declassified from U.S. government archives? For starters, where are:

- Kammler's detailed statement to the U.S. Counter-Intelligence Corps (likely in May 1945)?
- Ernst Englander's "as soon as possible" report to George McDonald about what he learned from interrogating Kammler (likely in November 1945)?

[For background information and more details, see Agoston 1985; Döbert 2015; Döbert and Karlsch 2019; Karlsch 2014; Michalski et al. 2019; Reuter et al. 2019; Sulzer and Brauburger 2014, 2019a.]]

D.14.7 U.S. Inspections of Possible Nuclear Facilities

[At the end of the war, investigators from the United States personally inspected many of the facilities where German nuclear work may have occurred. Reports on what they found have never been publicly released.]

German Underground Structures [AFHRA C5098 frames 0886–0890]

HEADQUARTERS
UNITED STATES AIR FORCES IN EUROPE
Office of Asst. Chief of Staff A-2

AAF Station 379
APO 633, U S Army
29 August 1945

SUBJECT: German Underground Structures.

TO: Commanding General, U. S. Air Forces in Europe, APO 633, U S Army.

1. In compliance with your instructions, the following report on German underground structures is rendered.

2. This is based on the writer's personal observations during the period 14 May to 1 August 1945. It is of necessity in the nature of a preliminary report for an insufficient number of undergrounds were visited to make a complete report on so large a subject. Again, these installations were inspected primarily for their equipment installations of urgent ATI interests, rather than for the details of their construction. However, the main structural features were examined and noted.

3. A list of the undergrounds visited is attached hereto as Appendix 1. These varied in size from approximately five (5) to twenty-six (26) kilometers, lineal measure, of underground galleries. Dimensions of the galleries varied from four (4) to twenty (20) meters in width and five (5) to fifteen (15) meters in height, the floor space from twenty five thousand (25,000) to one hundred thirty thousand (130000) square meters.

4. All of the undergrounds examined are level entries driven into solid limestone, requiring drilling and blasting for excavation, to a soft, fine-grained sandstone which could be dug by pick alone. These last are all well supported by heavy masonry or concrete linings. Some of the solid limestone galleries are also lined. In all cases the workmanship (though chiefly done by slave labor) is excellent and the construction is of permanent nature for long endurance, rather than to meet temporary war construction.

5. All entries are in steep hillsides having slopes of thirty (30) degrees or more. In nearly every case an open cut was excavated in the hillside so that even the portals are under one hundred (100) feet, or more, of overburden. From the portals the rising slope of the surface increased the solid overburden rapidly to two hundred (200) to five hundred (500) feet.

CONCLUSIONS

6. Even though well drained, lighted and ventilated, these underground structures are, of necessity, inferior to surface buildings for housing industrial plants. Their only advantage is protection from bombing and they, therefore, have no place in a peacetime industry. Their continued existence is a military asset.

7. Well supported excavations under the protection of a deep solid rock overburden are extremely stable and are impervious to damage by attack from the air by any existing bomb. The future developments of the atomic bomb cannot now be predicted. However, to destroy the workings from the air, the entire overlying hill would have to be blown off, a matter of shattering solid rock, from above, to a depth of 200 feet or more. This is now considered impractical.

8. Neutralization of level entry undergrounds must include nearly complete destruction to be effective. Sealing the entrances only would be merely a short delaying action. However, where entry is by vertical, or inclined shaft, the destruction of the shaft may render reopening impractical under certain conditions. It would in any case cause a long delay.

9. So long as these undergrounds remain intact they are available for bombproof housings of important industries in any future war. It is recommended that careful consideration be given to their neutralization even though its accomplishment will be a difficult and costly work.

10. To approach this problem, it is recommended that all existing undergrounds be examined by personnel qualified to judge not only the strength of the supporting structures, but the character of the overlying rock, its structure, joints, bedding planes and other lines of weakness. Maps showing the underground galleries should also have the surface contours superimposed to show depth of overburden at all points. The above information is needed before any detailed plan of neutralization can be made.

11. It is believed that the most effective method will follow the general plan of blasting out the strategic supporting column of rock with explosive blasts strong enough to shatter the overlying rock along lines of natural weakness sufficiently to render its support impractical.

RECOMMENDATIONS

12. The overall problem can best be evaluated under the direction of a geologist with practical experience in underground development. He can correlated the primary factors:

a. the overlying rock structure and strength, with

b. its support.

With him should be associated men of extended practical experience in underground construction and an explosive expert.

13. It is recommended that this paper be forwarded to Headquarters, Army Air Forces, with the idea of selecting targets of above mentioned types for secret experiment of rocket propelled atomic bomb.

GEORGE C. McDONALD
Brigadier General, U.S.A.
Asst. Chief of Staff A-2.

APPENDICES

1. List of undergrounds examined.

Camp Gusen	Aircraft component factory
Camp St. Georgen	" " "
Camp Ebensee	" " "
Kahla	" " "
Between Kahla and Jena	Optical lens grinding plant.
Redl-Zipf	Oxygen making plant.

2. Attached is the map of the underground workings at Camp St. Georgen. This illustrates the general type of structure though it is more regularly laid out than the others.

[This document demonstrates several important facts:

- There were a very large number of German underground installations (the six that McDonald visited were only an "insufficient number," Point 2 and Appendix 1).

- The German underground installations were massive (Point 3—up to 26 km of galleries each, with the galleries up to 15 m high and up to 20 m wide), built with "workmanship" that was "excellent... for long endurance" (Point 4) and "well drained, lighted and ventilated" (Point 6).

- The German underground installations that he described sounded fully functional during the war, not still under construction and unoccupied at the end of the war.

- Allied personnel conducted detailed inspections of the underground installations, yet (with only a few exceptions) the results of those inspections, or even the facts that they occurred at all, have not been made public.

- The Allies removed urgent war-critical materials from the underground installations (Point 2). What materials could have been so urgently needed by the United States in its continuing war with Japan—perhaps materials related to nuclear weapons development?

- After the war, the Allies expended great effort to destroy and prevent access to the many underground installations (Points 8–12).

- Underground installations that were so numerous, so large, and so advanced could have provided suitable locations not only for the aircraft, lens, and oxygen production that McDonald mentioned, but also potentially for producing large rockets, nuclear materials or weapons, or other advanced weapons systems or components.

- McDonald could only describe what he observed. It is possible that some German underground installations were evacuated and/or destroyed by German troops before Allied military forces even arrived.

- Point 13: Presumably McDonald was not suggesting nuclear test strikes on these facilities in postwar Austria and Germany, which would cause radioactive contamination of the area, not be a "secret experiment" at all, and likely provoke negative reactions from local countries and from the Soviet Union. Rather, he was apparently suggesting that the United States should build test structures similar to those he described (likely in the southwestern United States or on a Pacific island) and then detonate an atomic bomb on that test structure to see how much damage the bomb could do.

- Point 13: During the war, Heinrich Himmler apparently wanted German underground facilities to be so well built that they could even survive an Allied strike by an atomic bomb (see p. 4592). McDonald may have been aware of that intention, and may have wanted to put it to the test (but somewhere else where the test could be conducted safely and secretly, as already discussed).

- Point 13: In August 1945, the U.S. was apparently preparing "secret experiment of rocket propelled atomic bomb." However, the only atomic bombs that the United States officially possessed were more Fat Man bombs weighing 3000-4000 kg (depending on the casing), and the largest rockets that the United States officially possessed were captured German V-2 rockets, which could not carry a payload that heavy. Officially the United States did not develop its first rocket-propelled atomic bombs until the early 1950s [Chuck Hansen 1988, pp. 189–191]. In August 1945, how could the U.S. military have, or expect to soon have, a rocket-propelled atomic bomb for a "secret experiment"? Does that suggest that the United States acquired German rockets larger than the V-2 that could carry a larger payload like the U.S. Fat Man? Does it suggest that the United States acquired a German atomic bomb (or plans thereof) that was smaller than the U.S. Fat Man? Or does it suggest that the United States acquired an advanced German rocket and atomic bomb that were already an integrated system? (There is also an earlier draft of this report with the comment about a rocket propelled atomic bomb added in handwriting [AFHRA C5098 frames 0990–0991].)

- McDonald was involved in preparing the U.S. Army Air Force's January 1945 "Evaluation of German Capabilities" that discussed existing German rockets larger than the V-2, as well as sites of possible German atomic bomb tests (see pp. 5336–5337). After the end of the war in Europe, he spent months visited highly secret German weapons production plants (Point 2 and Appendix 1). He knew that Hans Kammler survived the war, was in U.S. custody, and was being interrogated (see pp. 4931–4959). Thus McDonald was probably one of the best informed Americans in terms of his knowledge of the German secrets weapons programs.]

~~SECRET~~

I and Davis entered Czechoslovakian target yesterday morning and spent three hours with Dr. Patzochke, German director of the mines.

There has been intensive exploratory and development work at two out of three mines directed at increasing the production of uranium, bismuth, cobalt and nickel. The shaft of one mine has been extended to about twice its original depth, and a new underground shaft has been added to the other mine. Plans for sinking a shaft on a new site are prepared.

Uranium ore production has been increased from the equivalent of about one and one-half grams radium per year before the war to three and one-half grams per year in 1943 - 1944. From 1939 to 1944 inclusive ore equivalent to about fourteen grams radium was mined and concentrated at the mine site. These concentrates contain 60 per cent U 308 and were sent to Germany and Austria for radium extraction, and were divided equally between Auer, Buchler at Brunswick, and Goldschmidt at Tribach in Austria. Dr. Patzochke informed us that exploratory work indicates that mine could be maintained at present output for at least five years, and probably for at least ten years. It might even be possible to increase output to the equivalent of five grams of radium per year.

Radium and uranium refinery at site has been closed down since 1939, and only the concentration plant has been worked. This can handle ten tons of crude ore per day. Stocks consist of about four tons of 60 per cent concentrates, twenty tons of 10 per cent crude ore and three thousand tons of residues having a U 308 content not exceeding one per cent.

The mines used to be the property of the town until they were taken over by Auer. They will now presumably return to Czechoslovakian ownership. At present all directors are German, and most technical staff are Germans. We asked for and were given copies of some of the mine plans.

The town has not yet been occupied either by the United States or the Russian armies, and we were the first Allied soldiers to enter. The Russians were expected hourly from Carlsbad which made it necessary to reduce time spent in target area to minimum. There was a provisional Czechoslovakian Military Government in the town with whom we did not come into contact.

The mine shafts lend themselves to destruction, but we do not, repeat do not, recommend such an action in view of tactical and other general considerations. It would doubtless be possible to place contract for output of mines at a later date when ownership has been re-established, provided, of course, that we are not forestalled by our eastern Allies.

THIS DOCUMENT CONSISTS OF 3 PAGE(S)
NO. 1 OF 2 COPIES, SERIES A

TO :Major Britt

DATE: 22 October 1945

FROM :H.S. Lowenhaupt

SUBJECT: Joachimsthal Mines, Czechoslovakia:

Reports quoted: Review of production and reserves statistics, Joachimsthal Mines by G, C. Selfridge, 20 April 1944; Preliminary Report on Joachimsthal Mines, by Union Mines, 22 October 1943; Suppliment No. 1 to Preliminary Report by Union Mines, 25 January 1944; Report based on Notes of Dr. D.F. Hewett's Visit of 28 June 1926 by G.C. Selfridge, 25 March 1944; World Resources Report by G.W. Bain.

1. The mines are in the mountains north of Karlsbad, northwest Czechoslovakia.

2. They consist of deep workings in a series of 33 roughly north and south trending veins of great vertical extent.

3. There are three mines and five important veins:

West Mine:

The Geister vein, 1,400 feet deep, 1,970 feet long, having 10 developed levels.

The Schweizer vein, 1,500 feet deep, 3000 feet long, having 8 developed levels. The most productive in recent years.

East Mine:

The John the Evangalest vein, 1700 feet deep, 1500 feet long, having 12 levels.

The Hildebrand vein, 1700 feet deep, 1800 feet long, having 12 levels.

Edelleut Mine:

The Francisci vein, 755 feet deep, 2,000 long, having 9 levels.

4. The veins are 6 to 24 inches in width, being narrower towards the bottom. The U_3O_8 content across the vein is only about 1%, but the pitchblende occurs in lenses which are easily broken from the surrounding rock, so the processed ore averaves 60%.

5. Up to 1937, 450 metric tons of U_3O_8 had been mined. Mining at that time was averaging 15 metric tons a year.

SUBJECT:

6. Dr. G.W. Bain feels that 170 to 220 metric tons of U_3O_8 may be accredited to these mines as probable future production.

7. Captain Davis and Major Gattiger report (Memo, Smith to Groves, 22 May 1945) that the mine is conducting deep exploratory work and expects to produce 20 metric tons of U_3O_8 per year for 10 years. This 200 tons corresponds well with Bain's figure in (6) above.

1. Czechoslovak miners, formerly employed in the Pribram area, and now resettled with their families at Jachymov, Czechoslovakia, furnished the following general information on the pitchblende deposits in Jachymov:

DESCRIPTION OF URANIUM MINES, JACHYMOV.

There are three individual uranium mines at Jachymov. None of these fall under the supervision of the Czechoslovakia Ministry of Mines, nor the Czechoslovak Foreign Office. According to estimates made by the Soviet geologists the largest pitchblende deposits are in:

(a) "Werner" Mine or "Stola Bratrstvi"
(b) "Stalin" Mine formerly "Rovnost" Mine
(c) to a lesser extent in "Svornost" Mine

(a) "Werner" Mine is located about 2 km northeast of Jachymov. The "Werner" mine contains two vertical shafts which at present are in full operation. During the German occupation of Czechoslovakia, the Germans continued operations in this mine to the very last moment.

(b) "Stalin" Mine (formerly "Rovnost" Mine) is located in the southwest outskirts of Jachymov. This mine, now in operation, has only one entrance for both miners and bogietrucks.

(c) "Svornost" Mine is located in the northern section of the city of Jachymov. During the German occupation of Czechoslovakia, the Germans abandoned this mine and claimed it was unproductive. However, the Svornost mine kept on supplying most of Jachymov's Health Institutions with radio-

The difficulties encountered by the Soviets are greater than expected as most tunnels are flooded.

NUMBER OF EMPLOYEES AT JACHYMOV.

The total number of miners at Jachymov is still claimed to be between 235 and 250. Out of this total, 200 employees are German prisoners of war. These are generally considered as laymen. The remainder is composed of expert Czechoslovak miners lured into the Jachymov area by high wages, special rewards and a title to a former Sudeten German home.

The total number of miners now employed at Jachymov exceeds the number of miners employed by the Czechoslovak Ministry of Mines during the peak pre-war days. As explained, the Soviet demand for increased output cannot be met as most tunnels are very narrow and the streaks of pitchblende ore are very irregular. Thus the operation of one vein is limited to one or two workers. For this reason it is also difficult to ascertain just how many miners are employed in one individual mine.

GENERAL CONDITIONS OF JACHYMOV MINES

The Czechoslovak uranium miners met at the Jachymov week-end resort in Bozi Dar (north of Jachymov) bitterly complained against the Soviet destructive policy at Jachymov. In their enthusiasm and impatience to increase the output of pitchblende ore, the Soviet engineers completely disregarded all safety precautions. The tunnels not properly reinforced with lumber make mining more complicated and hazardous. In order to increase the individual productivity of the expert miners, the Soviets use Soviet food, cigarettes, liquor and luxury items as inducements. One miner summed up the present situation in the Jachymov mines as follows: "They (the Russians) will not need 99 years time to get all we've got down here".

LOCATION OF JACHYMOV URANIUM MINE OFFICES

The main offices of Jachymov mines formerly under Ministry of Mines were located in Praha, Czechoslovakia. Now all personnel and documents are at Jachymov under the supervision of the Soviets.

FOREIGN PERSONNEL AT JACHYMOV

The Czechoslovak miners claimed all work conducted in the Werner and Stalin mines is under the supervision of 8 or 10 Soviet Engineers who are only responsible to their superior Chief Engineer. The Soviet Geologists who conduct the search for additional uranium deposits in the vicinity of Jachymov north to the German border are billeted in Karlovy Vary. Only in emergencies do they remain in Jachymov. All roads leading to Jachymov are guarded from concealed positions by Soviet Security Agents. No road blocks or checking points are encountered upon entry to Jachymov, but the number of every car approaching the area is recorded. Foreign tourists visiting Jachymov are under constant surveillance. They usually do not run into any difficulties unless they disclose special interest in the uranium deposits or develop a walking habit that would take them into the vicinity of the mines.

The mines are guarded by the Soviets. Recently, several Czechoslovak soldiers appearing dangerously close to the mines became the targets of Russian bullets. In order to avoid unnecessary embarrassment to the Soviets, should this incident be unduly publicized, the Czechoslovak soldiers were immediately transferred.

COMMENT

The Jachymov Uranium mines are the subject of many conflicting reports. Official visitors taken into Jachymov for the "Cooks' Tour" are convinced that the abandoned concentration plant and flooded tunnels are a definite proof that the mines are not in operation. The submitted details originating from the Czechoslovak miners are herewith presented to submit additional verification that the Jachymov mines, completely out of control of the Czechoslovak Ministry of Mines and the Czechoslovak Foreign Office, but under special Czechoslovak - Soviet agreement are producing pitchblende ore for the Soviets without a single ounce of ore remaining in Czechoslovakia. Attempts are being made to determine the exact production capacities and the details of the Czechoslovak-Soviet agreement.

Underground Factories in Europe [AFHRA C5098 frames 0931–0932]

Underground Factories in Europe

Commanding General, Air Material Command, Wright Field, Dayton, Ohio. Attn: TSDIN

1. In compliance with Restricted letter, Subj: Request for Information on German Underground Plants, dated 19 Oct 1945 (Incl. 1), a report has been prepared entitled "Preliminary Report on Underground Factories and Facilities in Germany and Austria" (Incl. 2).

2. The completed survey disclosed a considerably larger number of German underground factories than had hitherto been suspected. In addition to Germany and Austria, the Germans built underground factories in France, Italy, Hungary and Czechoslovakia. Although the Germans did not go underground on a large scale until March, 1944, they managed to get approximately one-hundred and forty three (143) underground factories into production by the last few months of the war. Statistics are as follows:

a. Number of factories in production by the end of the war......................	143	
b. Number of factories being built, being excavated, and planned............	107	
c. Number of factories reported, and potential sites (mines and caves).....	600	
Grand Total......	860	[850?]

3. In summarizing the results of the survey three facts are outstanding:

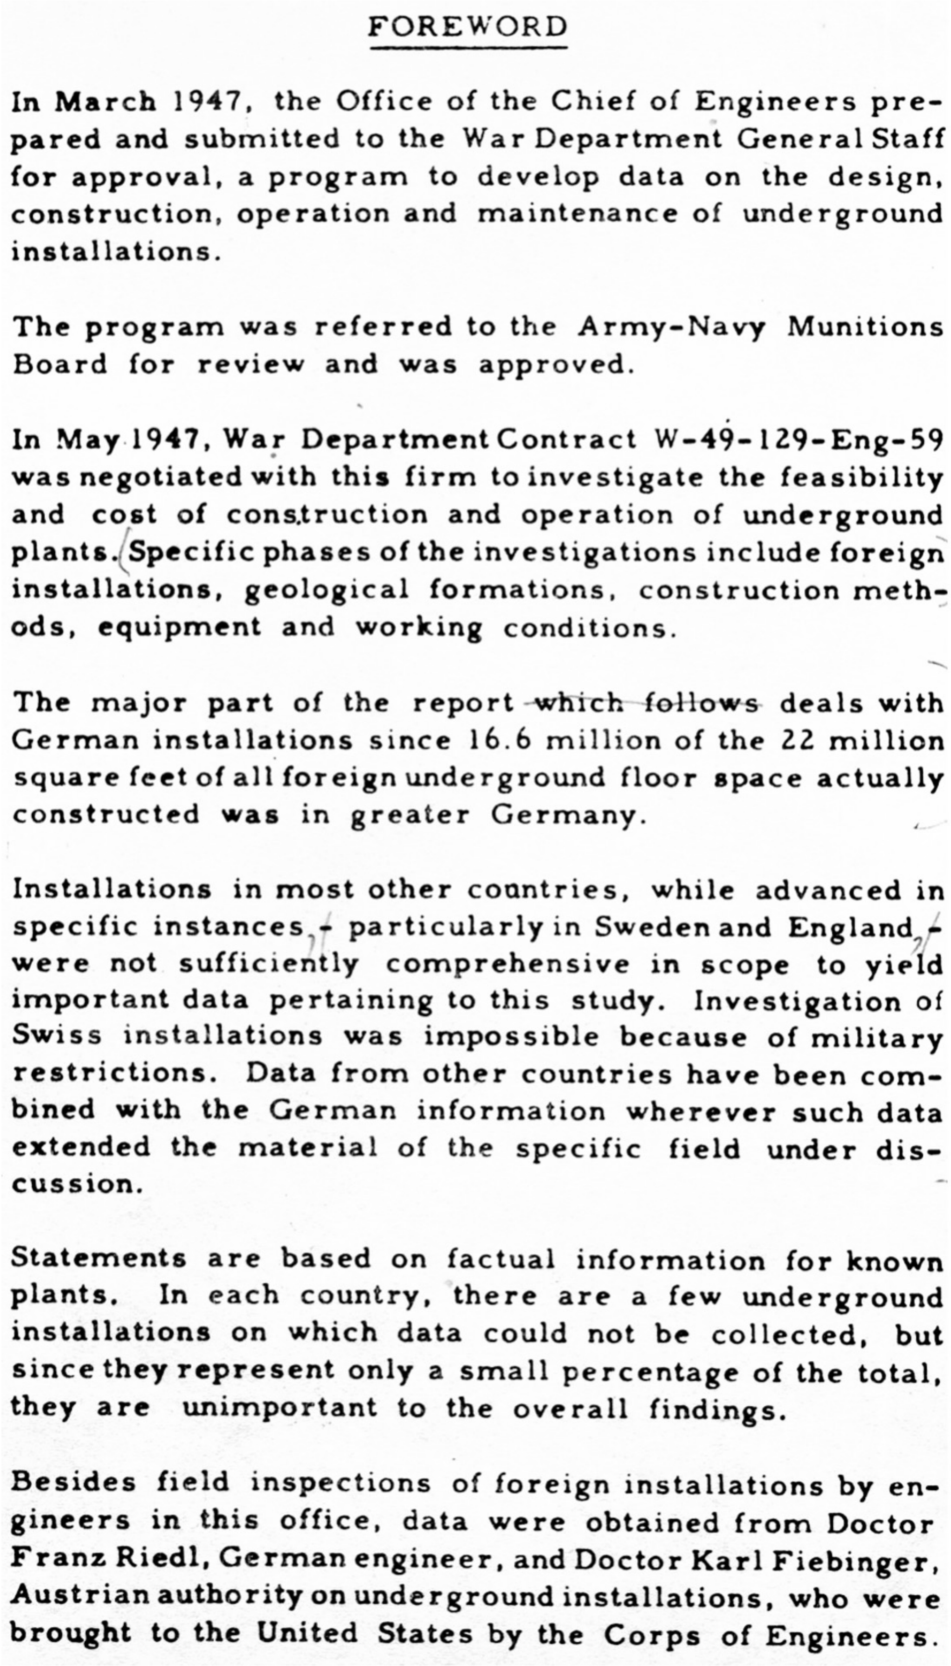
a. The tremendous advantages of placing factories under ground are concealment and protection. Of these two concealment is at least of equal importance as protection, since more underground factories remained undetected during the war than were discovered prior to the termination of hostilities. This is especially true of those located in old mines and natural caves where the presence of the mine or cave was not known to the Allies.

b. Self-contained underground factories are practical for any industry with the possible exception of those classified as heavy industries. All technical problems, mainly ventilation and air conditioning, appear to have been solved by the Germans by the end of the war.

c. The Germans initiated the movement of industry under ground so late that the program did not have an opportunity to seriously affect the outcome of the war. It is a matter of conjecture as to what would have occurred if the Germans had gone under ground before the beginning of the war.

[Where are detailed reports on what was in all of these facilities?

How much work in these facilities was buried, overlooked, and forgotten?]



FOREWORD

In March 1947, the Office of the Chief of Engineers prepared and submitted to the War Department General Staff for approval, a program to develop data on the design, construction, operation and maintenance of underground installations.

The program was referred to the Army-Navy Munitions Board for review and was approved.

In May 1947, War Department Contract W-49-129-Eng-59 was negotiated with this firm to investigate the feasibility and cost of construction and operation of underground plants. Specific phases of the investigations include foreign installations, geological formations, construction methods, equipment and working conditions.

The major part of the report ~~which follows~~ deals with German installations since 16.6 million of the 22 million square feet of all foreign underground floor space actually constructed was in greater Germany.

Installations in most other countries, while advanced in specific instances,- particularly in Sweden and England,- were not sufficiently comprehensive in scope to yield important data pertaining to this study. Investigation of Swiss installations was impossible because of military restrictions. Data from other countries have been combined with the German information wherever such data extended the material of the specific field under discussion.

Statements are based on factual information for known plants. In each country, there are a few underground installations on which data could not be collected, but since they represent only a small percentage of the total, they are unimportant to the overall findings.

Besides field inspections of foreign installations by engineers in this office, data were obtained from Doctor Franz Riedl, German engineer, and Doctor Karl Fiebinger, Austrian authority on underground installations, who were brought to the United States by the Corps of Engineers.

D.14.8 German and Austrian Scientists in the United States

[Many German and Austrian scientists who appear to have been involved in the nuclear program visited the United States and/or United Kingdom after the war, and may have provided information about wartime German work. See p. 4993 for a few examples. Files for some scientists are still not available to the public. For example, almost the complete file of nuclear physicist Otto Haxel has been redacted (p. 4994), and Wernher von Braun's file is missing entirely [NARA RG 330, Entry A1-1B].

How much influence did information, scientists, and materials from the German nuclear weapons program have on the U.S./U.K. nuclear programs, both during and after the war? Detailed information, scientists, and materials from the German program began arriving in the United States and United Kingdom no later than late 1944, and continued for several years after the war.

The late-wartime and postwar influx of scientists and engineers who were from or at least had knowledge of the German nuclear program included:

Karl-Friedrich Bonhoeffer
Wernher von Braun
Rudolf Brill
Adolf Busemann
Walter Dornberger
Rudolf Edse
Krafft Ehricke
Wilhelm Eitel
Gerhard Falck
Karl Fiebinger
Wolfgang Finkelnburg
Rudolf Fleischmann
Siegfried Flügge
Walter Glaser
Wilhelm Groth
Gottfried Guderley
Paul Harteck
Otto Haxel
Richard Herzog
Johannes Hans Jensen
Willibald Jentschke
Ulrich Jetter
Georg Joos
Hartmut Kallmann
Hans Kammler
Gerald Klein
Stanley Kronenberg
Heinz Maier-Leibnitz
Werner Maurer
Hugo Neuert
"Dr. Niels" (Walter Nielsch?)
Edgar Petersen
Heinz Schlicke
Erich Schumann
Otto Schwede
Edmund Sorg
Kurt Starke
Ernst Stuhlinger
Hans Suess
Herbert Wagner
Wilhelm Westphal
Friedwardt Winterberg
Karl Wirtz
Gernot Zippe
Etc.

This list is by no means exhaustive. Furthermore, countless other scientists were interrogated in Europe. See also Section D.14.9 for examples of additional people. The complete files on all of these scientists and engineers should be sought and released.

A number of the above scientists appear to have been closely tied to German work on H-bombs, and may have especially aided the U.S. H-bomb development program between 1945 and 1954. Some of the scientists may have also been able to contribute to improvements in U.S./U.K. fission bombs (e.g., smaller sizes and higher efficiencies) and fission fuel production (such as the uranium centrifuges of Groth, Harteck, and Zippe).

There is a great need for archival researchers and historians to investigate this area in much more detail in the future.]

Screened by NARA (RF) 07-30-2024 FOIA # 87460 DOCID: 33801537

NARA RG 319, Entry A1-134B, Folder XE301420 Haxel, Otto

AGENT REPORT
(SR 380-320-10)

1. NAME OF SUBJECT OR TITLE OF INCIDENT: HAXEL, Otto (C)
RE: JIOA

2. DATE SUBMITTED: 4 February 1957

3. CONTROL SYMBOL OR FILE NUMBER: 301420

4. REPORT OF FINDINGS

(PHYSICAL PRESENCE) On 23 January 1957, a discreet check revealed SUBJECT to be physically present at his listed residence at 35 Moenchhofstrasse, Heidelberg (MV 7873), Germany.

5. TYPED NAME AND ORGANIZATION OF SPECIAL AGENT: SIDNEY FRIEDLAND, 66th CIC Group

6. SIGNATURE OF SPECIAL AGENT: Sidney Friedland

AGENT REPORT
(SR 380-320-10)

1. NAME OF SUBJECT OR TITLE OF INCIDENT: HAXEL, Otto (C)
RE: JIOA

2. DATE SUBMITTED: 4 February 1957

3. CONTROL SYMBOL OF FILE NUMBER: 301420

4. REPORT OF FINDINGS

(EMPLOYMENT) On 24 January 1957, SUBJECT was observed at his listed place of employment at the Physics Institute, University of Heidelberg, 7 Albert Ueberlestrasse, Heidelberg (MV 7873), Germany.

AGENT REPORT
(SR 380-320-10)

1. NAME OF SUBJECT OR TITLE OF INCIDENT: HAXEL, Otto (C)
RE: JIOA

2. DATE SUBMITTED: 6 August 1957

3. CONTROL SYMBOL OF FILE NUMBER: XE-301420

4. REPORT OF FINDINGS

On 5 August 1957, the records of the Residents' Registration Office, Heidelberg (MV 7873), West Germany, were checked and revealed that SUBJECT is residing at 26 Moenchhofstrasse, Heidelberg, West Germany. A discreet physical check of SUBJECT's residence was made and revealed that SUBJECT was not present. A discreet phone call to SUBJECT's residence revealed that SUBJECT and his wife are presently in Baden Baden (MV 4302), West Germany, and that they will return to Heidelberg, West Germany on 31 August 1957.

AGENT REPORT
(SR 380-320-10)

1. NAME OF SUBJECT OR TITLE OF INCIDENT: [illegible], Karl Herman (C)
RE: [illegible]

2. DATE SUBMITTED: 3 March 1959

3. CONTROL SYMBOL OR FILE NUMBER: [illegible]

4. REPORT OF FINDINGS

On 25 February 1959, records of the Einwohnermeldeamt (Resident's Registration Office), Heidelberg (MV 7873), West Germany, were checked and a discreet physical check of SUBJECT's residence and employment was made and revealed that SUBJECT is residing at 72 Neunheimerlandstrasse, Heidelberg, West Germany, and working at the Kaiser Wilhelm Institute, 29 Jahn Strasse, Heidelberg, West Germany, as listed.

AGENT REPORT
(SR 380-320-10)

1. NAME OF SUBJECT OR TITLE OF INCIDENT: HAXEL, Otto (C)
RE: JIOA

2. DATE SUBMITTED: 3 October 1960

3. CONTROL SYMBOL OR FILE NUMBER: XE-301420

4. REPORT OF FINDINGS

On 26 September 1960, the records of the Einwohnermeldeamt (Resident's Registration Office), Heidelberg (MV 7873), West Germany, were checked and discreet physical checks of SUBJECT'S residence and place of employment were made and revealed that SUBJECT is residing at 2 Moenchofstrasse, Heidelberg, West Germany, and working at the Physics Institute, University of Heidelberg, 7 Albert Ueberlestrasse, Heidelberg, West Germany, as listed.

The following information was received by phone from L&S Office Marburg, Wednesday, 17 Sept 47, thru Mrs. Steinbacher:

Flügge, Siegfried, Dr.

Date of birth: 16 March 1912

Place of Birth: Dresden, Saxony, Germany

Present address: Marburg/Lahn, Wilhelm Roser Str. 33 A

Present employment: as professor at University of Marburg (ordentlicher Professor)

Special Field: Nuclear Physics (Struktur dor Materie)

Background information:

from 1918 - 1921: attended elementary school, Dresden

" 1921 - 1929: " high school (Gymnasium) in Dresden

" 1929 - 1930: attended Technical High School, Dresden.

" 1930 - 1933: at University in Göttingen

" 1933 Doctor of Physics at University of Göttingen.

" 1933 - 1935: worked at University of Frankfurt as Scientific Assistant.

" 1935 - 1937: lectured at University of Leipzig

1937 to Berlin

" 1937 - 1942: worked in chemical department of the Kaiser-Wilhelm-Institute in Berlin, Dahlem.

" 1942 - 1944: assistant at the Institute of Scientific Research of the Reichspost, Berlin

" 1940 - 1944: lectured at the University of Berlin

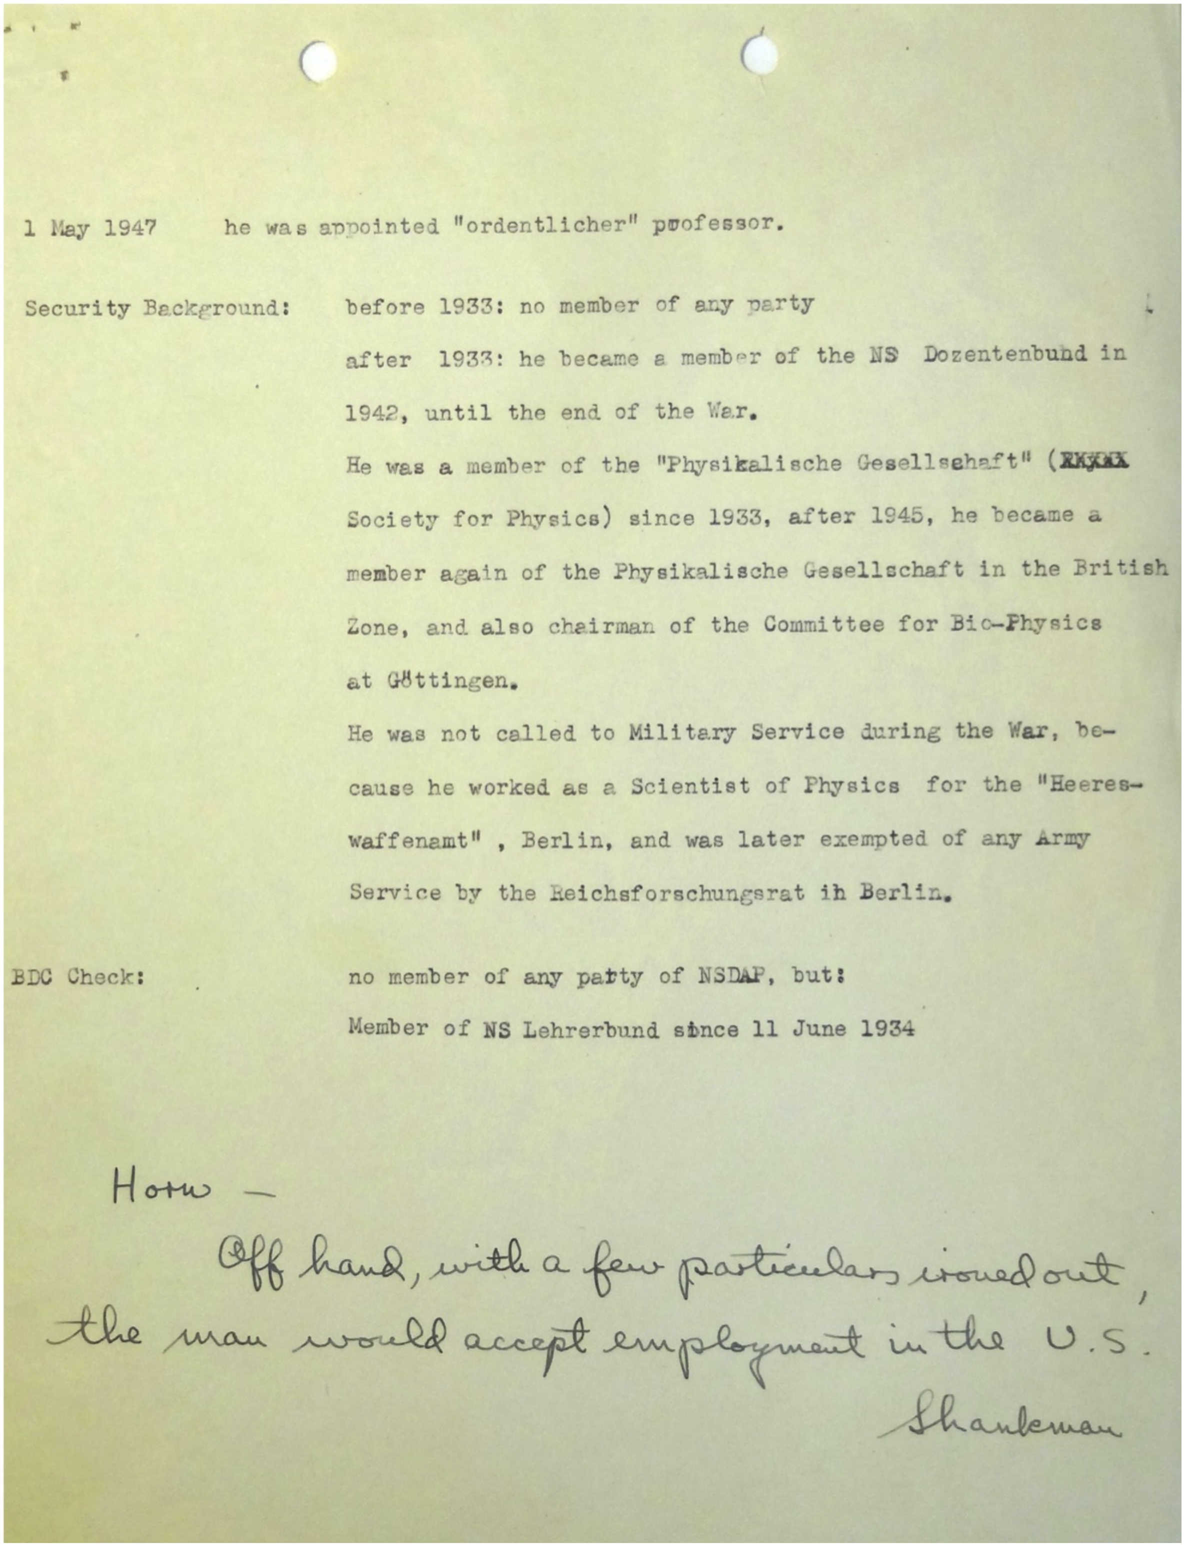
" 1944 appointed professor (ausserordentlicher) at the University of Königsberg.

After the surrender, he went to Göttingen, where he was employed as Professor for History of Physical Science from 1945 - 1947.

Figure D.987: During the war, Flügge worked for the Reichspost, Heereswaffenamt (also listed as University of Berlin since Erich Schumann was at both), Kaiser Wilhelm Institutes, Reichsforschungsrat, and University of Königsberg in East Prussia (said to have fission reactors, pp. 3928, 4578) [NARA RG 319, Entry A1-134B, Box 202, Folder XE196681 Siegfried Fluegge]. He also apparently worked at St. Georgen an der Gusen (p. 3882), another suspected nuclear facility.

DECLASSIFIED
Authority NND007017

NARA RG 319, Entry A1-134B, Box 202, Folder XE196681 Siegfried Fluegge



1 May 1947 he was appointed "ordentlicher" professor.

Security Background: before 1933: no member of any party

after 1933: he became a member of the NS Dozentenbund in 1942, until the end of the War.

He was a member of the "Physikalische Gesellschaft" (Society for Physics) since 1933, after 1945, he became a member again of the Physikalische Gesellschaft in the British Zone, and also chairman of the Committee for Bio-Physics at Göttingen.

He was not called to Military Service during the War, because he worked as a Scientist of Physics for the "Heereswaffenamt", Berlin, and was later exempted of any Army Service by the Reichsforschungsrat in Berlin.

BDC Check: no member of any party of NSDAP, but:

Member of NS Lehrerbund since 11 June 1934

Horn —

Off hand, with a few particulars ironed out, the man would accept employment in the U.S.

Shankman

SECRET

Memorandum to Colonel L. E. Seeman

from D. C. G. Gattiker

German scientists:

With reference to the points you raised with me the other day Welsh gives me the following information:

1) GROTH is definitely in Hamburg.

2) FLUEGGE is still at Marburg. His removal by the U. S. authorities to the University of Chicago would be acceptable to the British.

3) The list of scientists submitted by Welsh was intended to include scientists in the British and U. S. zones only: FISCHER and FUNFER, both believed to be in the French zone, were included in the list in error, although the exact whereabouts of FUNFER is notcertain.

1. Subject is listed on JIOA Special (hot) List (see letter, this headquarters, file D-219210, dated 21 September 1948 and letter, this headquarters, file D-247540, dated 5 October 1948).

2. As outlined in above referenced letters, it has become increasingly important that CIC be aware of every movement and activity of persons residing in the U.S. Zone or the U.S. Sector of BERLIN, who are listed on the JIOA Special (hot) List. Every effort to prevent subject from leaving his area of residence without this organization's knowledge must be made. The following are the minimum requirements:

a. The placing of the subject on intermittent mail and telephone watch list. Done

b. The obtaining of subject's schedule of daily habits (regarding time he goes to work, to lunch, etc.), including addresses frequented and persons contacted. Recording of this schedule is necessary to definitely ascertain subject's location at any time.

c. Description and, where possible, pictures of subject's residence and place of business or employment.

d. Names and descriptions of persons occupying or frequenting subject's residence or place of business. (For use as informants.)

e. All available background information on subject.

3. It is desired that a report on the above requirements and your comments regarding the use of the persons described in sub-paragraph d, above, be forwarded to this headquarters by 10 February 1949.

1. The attached Agent Report is forwarded in compliance with the request made by your Headquarters in Top Secret letter, Subject and File as above, dated 7 December 1948.

2. In view of the impossibility of maintaining a continued surveillance of the SUBJECT due to his habits, the nature of his neighborhood, and the location of his dwelling, it is planned to check his activities mainly through his maid, DOENGES. As is indicated in the inclosed report, it is impossible for a stranger to be in the neighborhood for any length of time without exciting suspicion.

3. This office has been informed by Military Government, Land Hesse, through Sub-Region Wiesbaden, that on one of his trips to WIESBADEN (K51/M36), the SUBJECT complained to MG that he was being surveilled, possibly by CIC. In the opinion of this office, the SUBJECT's suspicions do not reflect on the handling Agent, but may be taken as additional proof of the difficulty of the requested surveillance.

Professor Edward Teller, Physics Dept.
University of Chicago

[See document photo on p. 4996.

In 1947, Edward Teller was arguably the leading theoretical physicist of the U.S. nuclear weapons program, since most of the other prominent physicists from the Manhattan Project returned to civilian projects after the war. Throughout the 1940s, Teller was obsessed with creating a working fusion (hydrogen or H) bomb that would be much more powerful than the Manhattan Project's fission bombs. In 1946, a panel of other U.S. physicists concluded that Teller's proposed "classical Super" design for an H bomb was unlikely to work and that they did not know how to improve upon it, so in 1947 Teller would have been especially desperate for advanced nuclear weapons design solutions.

Siegfried Flügge was arguably the leading theoretical physicist of the wartime German nuclear weapons program, although apart from two very early and introductory publications (p. 3366), that was far from public knowledge at that time (or even today).

Some German-speaking scientists who had already settled in the United States, such as Hermann Mark and Theodore von Kármán, actively worked to bring many other German-speaking scientists to the United States after the war. However, I am not aware of other examples of Edward Teller actively recruiting German-speaking scientists from Europe after the war.

Thus this letter shows an extraordinary degree of interest and a singular focus. The leading physicist of the U.S. nuclear weapons program was "very desirous to obtain the services" of the leading physicist of the wartime German nuclear weapons program, who could "be of marked assistance in carrying out" an unspecified physics program "of interest and importance to the national security."

If the United States had discovered, sometime after the war, that Germany had actually had an advanced nuclear weapons program, it would have needed a particular type of person to help interrogate people who were most closely associated with that program and who could provide the most detailed technical information about it. Specifically, the United States would have needed someone (the fewer people the better, for security reasons) who:

- Was a physicist with an intimate knowledge of nuclear weapons designs from the Manhattan Project. (Many potential candidates, such as Theodore von Kármán and Samuel Goudsmit, did not have that knowledge, so this criterion rules them out.)
- Was fluent in German, including very technical German.
- Was extremely close to the U.S. military, and could be trusted to strongly advocate for its interests and to religiously keep its secrets.

There would have been a number of possible candidates for that position (see p. 1549), but those best matching the above three qualifications probably would have been Edward Teller, Hans Bethe, J. Robert Oppenheimer, and John von Neumann. Of those four, after the war only Teller was still truly focused on nuclear weapons designs. Teller would have been the ideal physicist to help interrogate top scientists from the German nuclear program such as Flügge, or top administrators from the program such as Hans Kammler (if he was indeed in U.S. custody), in order to learn as many technical details as possible about the German program's weapons designs, production methods, and results.

Flügge did eventually visit the United States in 1949–1950 and 1953. It is probably no coincidence that those were critical periods for the development of the country's first (cryogenic) H-bomb and its first dry (lithium deuteride) H-bomb, respectively. It seems virtually certain that even before those visits, while he was in Europe, Flügge was also interrogated in detail by U.S. scientists (perhaps Teller himself) and intelligence officials; otherwise Teller would not have known to make this specific request.

Can the details of Flügge's U.S. visits, work, and interrogations be located in archives and released?

As shown on pp. 4997–5003 and in a number of other declassified documents in that same file [NARA RG 330, Entry A1-1B, Box 43, Folder Flügge, Siegfried], when not in the United States, Flügge was placed on the Top Secret JIOA K "hot list," and very closely and constantly monitored for at least a decade after the war. The U.S. official who issued those orders was none other than Lt. Col. George R. Eckman, who had been the Executive Officer of the Alsos Mission [p. 3333 and https://www.ikn.army.mil/apps/MIHOF/biographies/Eckman,%20George.pdf]!

Importantly, these files on Flügge (pp. 4998–4999) also prove that this leading physicist of the German nuclear weapons program worked with the:

- Reichspost (Post Office).
- Heereswaffenamt (Army Ordnance Office).
- Kaiser Wilhelm Institutes.
- Reichsforschungsrat (Reich Research Council).
- University of Königsberg in East Prussia (said to have fission reactors, pp. 3928–3929, 4578–4579).
- He also apparently worked in Austria at St. Georgen an der Gusen (p. 3882), another suspected nuclear facility.

This appears to demonstrate high-level scientific coordination of the nuclear activities among many different organizations throughout the Reich.

How much did the United States know about the German nuclear weapons program's structure (e.g., that Flügge was its leading physicist) and accomplishments (e.g., that it had successfully developed fission bombs and had conducted advanced work on H-bomb designs, lithium deuteride, fusion boosting, etc.) prior to Teller's request? How much did it ultimately learn?

Teller's highly specific and urgent request, presumably based on his own or other classified post-war U.S. intelligence on the wartime German nuclear program, strongly suggests that Flügge was involved not only in the design of German fission bombs (see p. 3366 and Section D.8), but also in the design of German H-bombs (Section D.9).

Although the Soviet Union detonated its first known fission bomb in August 1949, Flügge was kept on the JIOA K "hot list" and closely monitored by the United States until at least the end of 1954. Even the documents mentioning the U.S. surveillance of Flügge (with no military or scientific details) were classified Top Secret, which seems extraordinary. Moreover, those files were finally downgraded to Confidential in January 1957. All of that is further evidence that Flügge had detailed knowledge of not just fission bombs but also H-bombs, which the Soviet Union did not fully perfect until November 1955 (RDS-37). The United States kept Flügge on a very tight leash, and even classified any mention of that leash as Top Secret, until the Soviet H-bomb program had reached a level of technological maturity at which it no longer would have needed Flügge's knowledge about H-bomb design.

Georg Stetter and his fellow Austrian nuclear scientists were also deeply involved in the wartime German H-bomb program (pp. 4330–4345). Just as they did with Flügge, the United States kept Stetter under very close supervision until the 1950s, presumably until he too would no longer have been helpful for the Soviet H-bomb program (pp. 4788–4800). And like Flügge, some members of Stetter's team were brought to the United States after the war to work temporarily or permanently.]

PROCUREMENT OF SERVICES OF W. GROTH FROM THE AIR FORCES

I spoke with Col. Harris, Hdqrs. ARDC, 5 West Baltimore, Baltimore, Mayland, this morning concerning the transfer of W. Groth to an Atomic Energy Commission contractor. Harris has been unable to track down any information on whether Groth is actually being brought into this country or not. They have not had any official notification of his coming. He did indicate, however, that should Groth be brought in by the Air Forces they would be willing to release him to us.

G. H. Morrison. How Adolf Hitler Lost the Atomic Bomb. *The Argus* (Melbourne). 6 October 1945, p. 2. https://trove.nla.gov.au/newspaper/article/12145557/631795

When Hitler learned that two German scientists had at last discovered a method by which it would ultimately be feasible to split uranium atoms when and as required, he imagined that Germany would soon hold a weapon whose mere possession would force her enemies to capitulate unconditionally. Hence his mysterious reference in the first days of the war to "a secret weapon" which, he said, he hesitated to use because of its deadliness. [...]

Again and again, Goebbels proclaimed the coming of the secret weapon that was to give Nazi Germany immediate and decisive victory. Over and over again Goebbels urged that "time was on the side of Germany." Just how far German atomic research had gone we were unable to discover. But it was quite certain the Germans were on the right track. [...]

On the laboratory scale U 235 was isolated for the first time in Germany in 1940. Even that, however, was far from being the end of the job of unravelling the skein of theoretical enigmas. Each problem solved raised some new problem. But German scientists stuck frantically to the task; and, as Professor Westphal, principal of the Berlin Technical High School, has since revealed, the Germans had solved the last laboratory problem in atom-splitting by 1944. That was about the time Goebbels began to assure his compatriots that the secret weapon would soon be in use.

[George H. Morrison (U.S., 1921–2004), an analytical chemist, worked on uranium purification and enrichment for the Manhattan Project: https://paw.princeton.edu/memorial/george-h-morrison-48

What exactly did Wilhelm Westphal do in Germany during the war and in the U.S. after the war?]

Dieter Hoffmann and Mark Walker, eds. 2007. *Physiker zwischen Autonomie und Anpassung.* Weinheim: Wiley. p. 340.

Ein Brief von Rudolf Ladenburg an Max von Laue, unmittelbar nach Erhalt dieses Artikels verfasst, führt uns zu einer weiteren Pointe:

"Otto Hahn's Artikel in der Göttinger Universitätszeitung bringt die Entlassung deutscher Professoren mit dem amerikanischen Angebot Professoren nach USA einzuladen in Zusammenhang. Wissen Sie von Kollegen, die erst entlassen + nun nach USA abgereist sind? Ich weiss nur, daß Westphal in USA ist + dass Joos hierher Anfang Juni abgereist ist [. . .] Westphal war, soweit ich weiss, nie abgesetzt + Joos ist nach kurzer Zeit wieder eingesetzt worden. In seinem Fall war die Absetzung, wie ich gehört habe, durch eine (unentschuldbare) Namensverwechslung verursacht."93)

A letter from Rudolf Ladenburg to Max von Laue, written immediately after receipt of this article, leads us to another point:

"Otto Hahn's article in the Göttingen University newspaper connects the dismissal of German professors with American offers to invite professors to the USA. Do you know of any colleagues who were first dismissed + have now left for USA? I only know that Westphal is in USA + that Joos left here at the beginning of June [...] Westphal, as far as I know, was never dismissed + Joos was reinstated after a short time. In his case, the removal, as I have heard, was caused by an (inexcusable) confusion of names."93)

D.14.9 Other Intelligence Services

[There is evidence that other U.S. investigators, as well as intelligence services from other countries, found information about the German nuclear program.

For U.S. involvement in a postwar shipment of five tons of zirconium that apparently came from the wartime German nuclear program, and that indicates a deeper U.S. understanding of the German nuclear program, see p. 4146.]

Ernest K. Lindley, Chief of Washington Bureau of *Newsweek*. Men and Secret Weapon for 1944 Invasion. *The World's News* (Sydney). 5 February 1944, p. 3.
https://trove.nla.gov.au/newspaper/page/14771447

Rumors concerning Germany's "secret weapon" continue to trickle through neutral capitals.

Recently a United Press despatch from Lisbon attributed to travellers arriving from the Reich the statement that the weapon is an explosive based on the release of atomic energy.

According to this report, small atomic bombs of tremendous explosive force would be dropped by "super-stratosphere" planes.

In both London and Washington, there are several degrees of reaction to the "secret weapon" talk.

- That it is partly propaganda, chiefly for German internal consumption, partly "nerve warfare" against the Allies.
- That the Germans may have something of nuisance value, but probably not in sufficient quantity to do much damage.
- That the weapon, even if dangerous, can be knocked out of enemy hands by such preventive measures as the bombing of the so-called Rocket Coast of Northern France.
- That the threat is serious enough to require every precaution possible and preparation for severe counter-action, such as air-borne gas attacks.

Bombing the "Rocket Coast" would not, for example, interfere with the use of an atomic bomb dropped from high-flying planes.

If the Germans have been able not only to perfect a super explosive but to produce it in quantity, it would be logical to expect them to use it on Britain when they think the invasion armies are about ready to jump off, hoping to disorganise the assault on Europe and stave off defeat in 1944.

Churchill, as his published comments indicate, regards reports of the "secret weapon" with respect, but not with alarm.

Other informed sources are braced for a vengeful, hurtful attack on Britain.

[By the end of the war, Ernest Lindley or his colleagues at *Newsweek* seem to have found high-ranking Allied officials who corroborated this early report. See p. 5022.]

Nazis' Atom Bomb Plans: Britain Ready a Year Ago. ***Daily Telegraph and Morning Post.*** **11 August 1945.**

Britain prepared for the possibility of an atomic bomb attack on this country by Germany in August, 1944.

It can now be disclosed that details of the expected effect of such a bomb were revealed in a highly secret memorandum which was sent that summer to the chiefs of Scotland Yard, chief constables of provincial forces and senior officials of the defence services.

An elaborate scheme was drawn up by the Ministry of Home Security for prompt and adequate measures to cope with the widespread devastation and heavy casualties expected if the Germans succeeded in launching atomic bombs on this country.

Reports received from our agents on the Continent early last year indicated that German scientists were experimenting with an atomic bomb in Norway. According to these reports the bomb was launched by catapult, and had an explosive radius of more than two miles.

In view of our own progress in devising an atomic bomb, the Government gave the reports serious consideration. Thousands of men and women of the police and defence services were held in readiness for several months until reliable agents in Germany reported that the bomb had been tested and proved a failure.

[Allied intelligence reports confirmed that Germany was developing an atomic bomb. A blast radius of over 2 miles or over 3200 meters corresponds to an explosive energy of approximately $(3200/85.5)^3 \approx 50{,}000$ tons of TNT, definitely nuclear and over twice the explosive energy of the first U.S. fission bombs.

Allied intelligence also confirmed that there was at least one attempted test of the German atomic bomb. It was reported to have been a failure and to have been associated with Norway (as the development and/or test location?). Was that the same failed atomic bomb test that Werner Grothmann mentioned in the North Sea in late 1943 (p. 4436)? The German nuclear program was producing heavy water at several sites in Norway (pp. 4027–4041), so were there other important aspects of the program in Norway? Dwight Eisenhower mentioned some sort of mysterious nuclear work at Trondheim that is otherwise unknown in publicly available documents (p. 5034). See also p. 4404.

The catapult launch suggests that the bomb may have been designed to be carried on a V-1 cruise missile, which was launched by catapult, or by some other aircraft or rocket that had been designed or modified to be launched by catapult. The Sänger-Bredt Silbervogel space plane would have been launched by catapult, and some versions of the A-9 rocket were designed to be launched by catapult. V-1 launch catapults were installed on German submarines in 1944 in order to attack Allied targets from offshore (pp. 5618–5627). There were major German submarine bases at Trondheim and other locations in Norway. And there were plans to arm the V-1 with a nuclear warhead (e.g, pp. 4896–4897). Could that have been the connection among these several mysterious pieces of intelligence?

Allied fears that the German bomb was nearly ready for deployment heightened in summer and autumn 1944. The Royal Air Force went to extreme lengths to bomb what appears to have been a German fission reactor and fuel reprocessing complex near Königsberg during the period 26–30 August 1944 (pp. 3928–3929). The first successful German nuclear test may have occurred in October 1944 (p. 4390).]

Big Projectile Reported New Hitler Weapon. ***Los Angeles Times.*** **30 September 1944. p. 3.**

SOMEWHERE IN FRANCE, Sept. 23 (Delayed.) (AP)—American 3rd Army troops have obtained information indicating that a 14-ton projectile with an explosive radius of three kilometers—almost two miles—is scheduled as the third in Hitler's series of vengeance weapons.

V-1 is the robot bomb launched from a platform.

V-2 is the long-range rocket fired from a carrier plane, for which the Germans are reported using the Heinkel 111.

V-3, so far as is known here, has not yet been used against either England or the attacking Allied armies.

Information disclosed the projectile is just short of 60 feet in length, is five feet five inches in diameter and weighs 14 tons at the take-off. Propelled by a mixture of liquid air and alcohol, it is shot into the air vertically, then is controlled by radio.

[Germany had many secret weapons in development, and the "V" number would simply indicate the order in which they happened to be publicly announced. The V-1 cruise missile or "robot bomb" had been fired at London since June 1944 and was well known by the time of this article. However, the existence of the V-2 or A-4 rocket was not publicly known when this article was released. V-2 or A-4 rocket attacks on Allied countries began on 8 September 1944 but were not publicly admitted by Germany until 8 November 1944, and by the United Kingdom until 10 November 1944. The aircraft-fired rocket referred to as "V-2" in this article was not the large A-4 rocket that ultimately gained the V-2 name, but rather a different weapon. It was likely the air-launched version of the V-1, which was indeed fired from Heinkel He 111 carrier planes (p. 1841). Alternatively, it might have been some other large, long-range air-to-ground missile, perhaps similar to the RASCAL liquid-propellant rocket that Walter Dornberger began creating (or recreating?) in the United States in 1946.

The V-3 rocket specifications given in the article closely match those of the A-4 rocket that became the real V-2. The diameter was indeed five feet five inches (1.65 meters), the launch weight was indeed 14 tons, the propellant was indeed liquid oxygen ("liquid air") and alcohol, and the rocket was indeed controlled by radio. The one specification that does not match is the stated length of "just short of 60 feet," or approximately 18 meters. The actual A-4 rocket length was approximately 14 meters. This could simply be a mistake in the Allied intelligence or reporting, or it could indicate that 18-meter-long extended versions of the A-4 rocket were being developed or built. The 14-meter A-4 rocket could carry a 1-ton payload of conventional explosives to a maximum range of approximately 350 km. An 18-meter extended version of the A-4 rocket (very similar to the postwar

Soviet SS-2 or R-2 missile that was produced using captured German technology) would have been able to accommodate more propellant, and therefore would have been able to carry a significantly heavier payload, such as a nuclear bomb.

A blast radius of 3000 meters corresponds to an explosive energy of approximately $(3000/85.5)^3 \approx$ 40,000 tons of TNT, definitely nuclear and approximately twice the explosive energy of the first U.S. fission bombs. This suggests that Germany had been developing and was close to deploying a nuclear bomb, and that its large rockets had been intended from the beginning to be delivery systems for that bomb, not merely for conventional explosives.

What exactly did the Third Army discover that formed the basis of this article? Where was "somewhere in France"?

Note that the AP report was delayed for a full week by Allied censors. What details did the censors not allow to be included?

29 May 1945 [...]

LORD VANSITTART

had the following Notice on the Paper: To ask His Majesty's Government whether they will take the initiative in proposing to the Allied Governments the inclusion in the terms imposed upon Germany of an Article providing that a permanent Inter-Allied Committee of Scientists should be established to examine and control, and if necessary to prohibit the use by Germany of, any scientific discovery or invention considered dangerous to the safety of mankind; and to move for Papers.

The noble Lord said: My Lords, I venture to think that this Motion speaks for itself. I would suggest that the Prime Minister's last war review speaks for it even more loudly. In the last war the ingenious barbarians sprang gas upon us. That was a prelude. There was an insufficient answer to that. In this war we have had the V1 and the V2. There was only a still more insufficient answer to the V1, and the V2 found no answer at all, or rather it would be fairer to say that the answer was the same as for V3, the multiple long-range artillery described by the Prime Minister which was destined to endow us with five shells per minute. The remedy found was the old-fashioned one of conquering the sites—that is to say, the answer of infantry and not of science. Even that remedy will not always be available, because ranges increase and sites recede. Indeed, the ranges, in a very short while, may be almost unlimited. Even with short ranges we were very nearly too late. If the V1 and the V2 had been brought into action one year sooner they would probably have made an end of this island, and if they had been brought in some years sooner, that is at the beginning of the war, they might well have meant the end of civilization. Therefore, in dealing with a nation that is periodically homicidal, I think no precaution is excessive.

All precautions are indispensable, because without them I think the end might well be the end of an American fairy story which we read when we were very young. No doubt that story was written with an inkling of Reno because they lived happy ever after for quite a little while. I say that because destructive science has got out of hand. German science, like German religion, German economics, German pedagogy, has been very largely militarized and unless we keep a firm hand on it we shall very likely have the V10 in less than ten years. It is not my purpose to paint lurid pictures of cities dissolved by pressing a button, though I suppose that is now within the bounds of possibility. We have had one lesson and it will be our own fault if we have another. [...]

What exactly does all this involve? It involves a good deal, and I submit that a good deal is a good deal better than another raw deal. It involves control of all German laboratories, both industrial and university. That in turn involves the use of an extensive and intensive intelligence service which must be drawn from all the Allies. [...]

30 May 1945 [...]

LORD BRABAZON OF TARA

[...] The V2 was a very different machine altogether, and I want to draw attention to some of the possibilities of the V2 before we forget it altogether. Your Lordships must remember that this propelling power is entirely in its infancy. This projectile goes up forty or fifty miles in its flight. There is no limit at all to the range it can go to because the resistance is so small at those heights. I want your Lordships to remember that although the charge was only about a ton in the case of the V2, in the future the effect of the power of explosives is going to be very much bigger than that which we have to-day. The noble Lord who is to reply is a physicist and I should like him to tell us, if he can, what are the possibilities of explosives of an atomic type, because there are absolutely frightening possibilities. Consequently this weapon is one which is bound to be developed. It is the physicist's dream or nightmare that he can produce these terrible explosives. [...]

I can well imagine some people, with mischief in their hearts, planning what they can do. And what can they do: They can rope off a few miles of their own hilly country, they can sink shafts, nominally mining shafts, they can make the parts of this instrument all over their country, assemble them in the mine, and be all ready for a really efficient V2 attack upon their selected enemy. I want you Lordships to remember this, that you will see no apparent Army, you will see no apparent Air Force, you will see no apparent Navy, but they will have the power latent to launch an attack on the great cities of their enemies and the power to devastate them the moment they declare war. Before Armies can possibly assembled, let alone march, the great cities of the enemy will be destroyed. I hope you will not think for a moment that I am wrong when I say that these weapons, with the new power of the explosives which are possible and with the new accuracy of direction, are not only things which can be directed against this county. They can be directed against America and if the resources in manufacturing power of a great country like America are destroyed, as they could be in twenty years' time, we must look upon the fact that we are tied up to America and if she goes we go. Consequently this power of attack, which might be developed quietly in any part of the world, is a danger we must face. [...]

THE EARL OF DARNLEY

[...] This method of warfare may possibly in the future not only destroy humanity but also destroy the globe on which humanity resides. That sounds fantastic but from the information I have been able to get I believe it is not as fantastic as it sounds. The atomic bomb, so the Press tells us, was in a state of three-quarters preparation at the end of the war and may possibly in a generation accomplish even this.

But before discussing what must be the final fatuity of mankind, it is necessary to look a little, as the noble Lord has done, into the future of the flying bomb and the rocket. As he told us so ably and humorously, it only needs a little imagination to see what might happen from the enlargement and perfection of these two missiles. He has told us that the war of the future may last only a few minutes, and as it is now the fashion to make war without any warning the whole thing would be over before anybody is even aware that it has taken place. The first man to touch the trigger will achieve possibly the complete paralysis of his adversary by methods against which there can be no possible defence. Navies and Armies and Air Forces will be completely useless and even the other defences of Press and propaganda will be similarly completely useless. The fighters of the future will be a band of troglodytic alchemists living in catacombs in hidden valleys who will deal out inhuman death to millions and destruction to a world whose beauties and whose interests they have long since given up the art of appreciating. The machinations of these people will remove the last vestige of the so-called romance and chivalry from the original war which the noble Lord so amusingly described.

And then as to the atomic bomb. I am not speaking as an expert, I am merely passing on what I have seen described in the Press, as others of your Lordships have seen it, and perhaps the noble Lord who is going to answer will be able to give me some further information upon it. It was stated in the Press that a bomb as big as a man's hand was ready, or almost ready, for use at the end of the war, and that it could have destroyed the whole of a city as large as London. When this atomic bomb is added to these brainless horrors of metal and explosives, which we have heard about to-day, I believe—and again I ask for information from the noble Lord who is going to reply—that it may possibly be a fact that the release of the cohesive particles of the atom, which at present can only be released through intensive bombardment by great electric force, may cause such a violent reaction that the force engendered may be sufficient to release the coherence in the atoms contiguous to the explosion. If this is the case, every atom in the world might disintegrate and the whole globe disappear. Is this, then, the frightful possibility envisaged by the marriage of force and science and their use as a method of settling human disputes?

[Although the theoretical possibility of atomic bombs had been publicly known for many years, in May 1945 the Manhattan Project had not yet produced an operational atomic bomb. The fact that the United States (with British assistance) was trying to produce an atomic bomb was highly classified and probably unknown to the members of the House of Lords, and they certainly would not have publicly discussed that program if they had known of it.

The repeated references by the members appear to be to German atomic bombs. They even stated that "a bomb [with a fission pit] as big as a man's hand was ready, or almost ready, for use at the end of the war, and that it could have destroyed the whole of a city as large as London," and they repeatedly pointed out the viability of German rockets as a delivery system for such a bomb. They spoke of devastating attacks against numerous British and American cities.

Although the members attributed that information to "the Press," media mentions of atomic bombs were heavily censored until August 1945, and there do not appear to have been any newspaper articles that provided this detailed information by May 1945.

The most straightforward explanation is that these members of the House of Lords had received information from wartime and early postwar Allied investigations of German programs to develop atomic bombs and advanced rockets to carry them. Can any relevant information be located among the archived papers of these members?]

Germany Calls on Allies to Turn the Other Cheek. *Toronto Daily Star*. 30 June 1945 p. 6. https://news.google.com/newspapers?id=O7E7AAAAIBAJ&sjid=KisMAAAAIBAJ&pg=719,18615434

London, June 30—(BUP)—The Germans came within six months of splitting the atom and possibly destroying the world in the process, Herbert Agar, special assistant to the U.S. ambassador, said in a speech last night.

"If the war had gone on another six months, it was quite possible that this planet would have ceased to exist, because it was probable that someone would have learned to break the atom without controlling it," Agar said.

"There was a danger that the Germans would learn how to split it first, and our scientists gave the date as Aug. 6 of this year. I sincerely believe that in a very few years human beings will know how to destroy the human race."

[In June 1945, Agar appeared to suggest that Germany planned its first nuclear attack for 6 August 1945. If that information was correct, the planned date may have been determined both by the production schedule of the weapon and its delivery system and also by the historical significance of that date for Germans. On 6 August 1870 Germany (still in the process of uniting under Prussia) won decisive battles against France, and on 6 August 1914 Germany launched its first U-boats to fight World War I. Later, 6 August 1945 turned out to be the actual date that the United States launched its first nuclear attack, on Hiroshima. Was that simply an extraordinary coincidence, or was the Hiroshima date chosen in part to send a political message to anyone who knew about the earlier German plans? See also:

G. Verner Edlund to Leslie Groves. 2 July 1945. Cable 44165. [NARA RG 77, Entry UD-22A, Box 160, Folder APR 45–Dec. '45]

From: US Military Attaché, London, England
To: War Department
Nr: 44165 2 July 1945

To MILID from Edlund for Davis to Groves for Smith serial number 44165. TOP SECRET.

London papers 30 June mention speech here by Commander Herbert Agar, Special Assistant to American Ambassador to the effect that someone would have learned TA [tubealloy—nuclear technology] without controlling it if war had continued another six months, danger that Germans would have learned first and our scientists gave the date as 6 August. Will interview subject and transmit clippings and report forthwith.

End

ACTION: Gen Groves

Monthly Intelligence Summary. April–June 1945. [NARA RG 77, Entry UD-22A, Box 168, Folder 202.3-1 LONDON OFFICE: Combined Intell Rpts.]

XII CENSORSHIP.

The period covered by this report has been marked by an increase in the problem of keeping newspapers in the U.K. from printing stories undesirable from a TA standpoint. An increasing tendency on the part of both the press and the censorship authorities to excuse stories on grounds of previous publication has been noted. A system is now in effect in U.S. whereby stories on TA, which are submitted to Censorship, are passed on to editors with a note asking that they not be published. Admiral THOMPSON, Chief Press Censor of the Ministry of Information, remains firm in his opposition to sending a circular to editors asking them not to print any reference to TA.

Colonel WARDEN, Chief Press Censor, SHAEF issued a directive to all SHAEF Censors ordering them to stop all TA stories regardless of previous publications.

The most embarrassing incident from the Censorship standpoint occurred when British papers carried a story reporting a speech by Commander AGAR, Special Assistant to the American Ambassador to Great Britain, in which AGAR stated that, “Had the war gone on a little longer, our scientists believed the Germans would have perfected TA.” This story resulted in several inquiries from the Press as to whether they would still be expected to refrain from printing stories on this subject. All such inquiries were answered in the affirmative.

Stories dealing with the sabotage of the heavy water plant at Norsk Hydro (Norway) also appeared in print during the period.

A party of SHAEF correspondents was taken to Norsk Hydro on a facility visit as a result of which fifteen stories were submitted to censorship authorities. These stories were all stopped.

Patrick S. Washburn. 1988. The Office of Censorship’s Attempt to Control Press Coverage of the Atomic Bomb during World War II.
https://files.eric.ed.gov/fulltext/ED295201.pdf

Yet, several days later, another “very bad bust,” as it was labeled by the Office of Censorship, originated in London. Cmdr. Herbert Agar, assistant to the U.S. ambassador to Great Britain, gave an address at an English college on June 29 that made no mention of atom splitting. However, three London newspapers obtained copies of his speech which contained some remarks that were deleted. These included the fact that American scientists estimated the Germans might have been able to split the atom by August 6, and thus if the war had lasted another six months, the Germans may have dominated the world.

The London newspapers rushed Agar’s written comments about atom splitting into print without checking with the government to see if they should be used, and then every American wire service filed stories. Since these were based solely on the newspaper stories, the English censor could not stop them because of prior publication. Agar was severely reprimanded by both the Navy and the American ambassador for being careless, but the Office of Censorship refused to try to get the wire services to suppress copy that had been approved by a foreign censor. However, it did discourage attempts by the United Press and others to further develop Agar’s remarks.

Charles A. Crowley to W. F. Heimlich. 31 August 1945. Headquarters United States Air Forces in Europe (Main). Berlin Intelligence Party. German V-1 and V-2 Personnel. [AFHRA C5094 frames 0957–0958]

1. In view of the fact that the wants of USAFE on V-1 and V-2 personnel have been satisfied, I am inclosing information on those men whose evacuation we have recommended. My memory of the conversation which we had a few weeks ago is to the effect that USFET was still anxious to either exploit or to know the exact location of these individuals. The list follows:

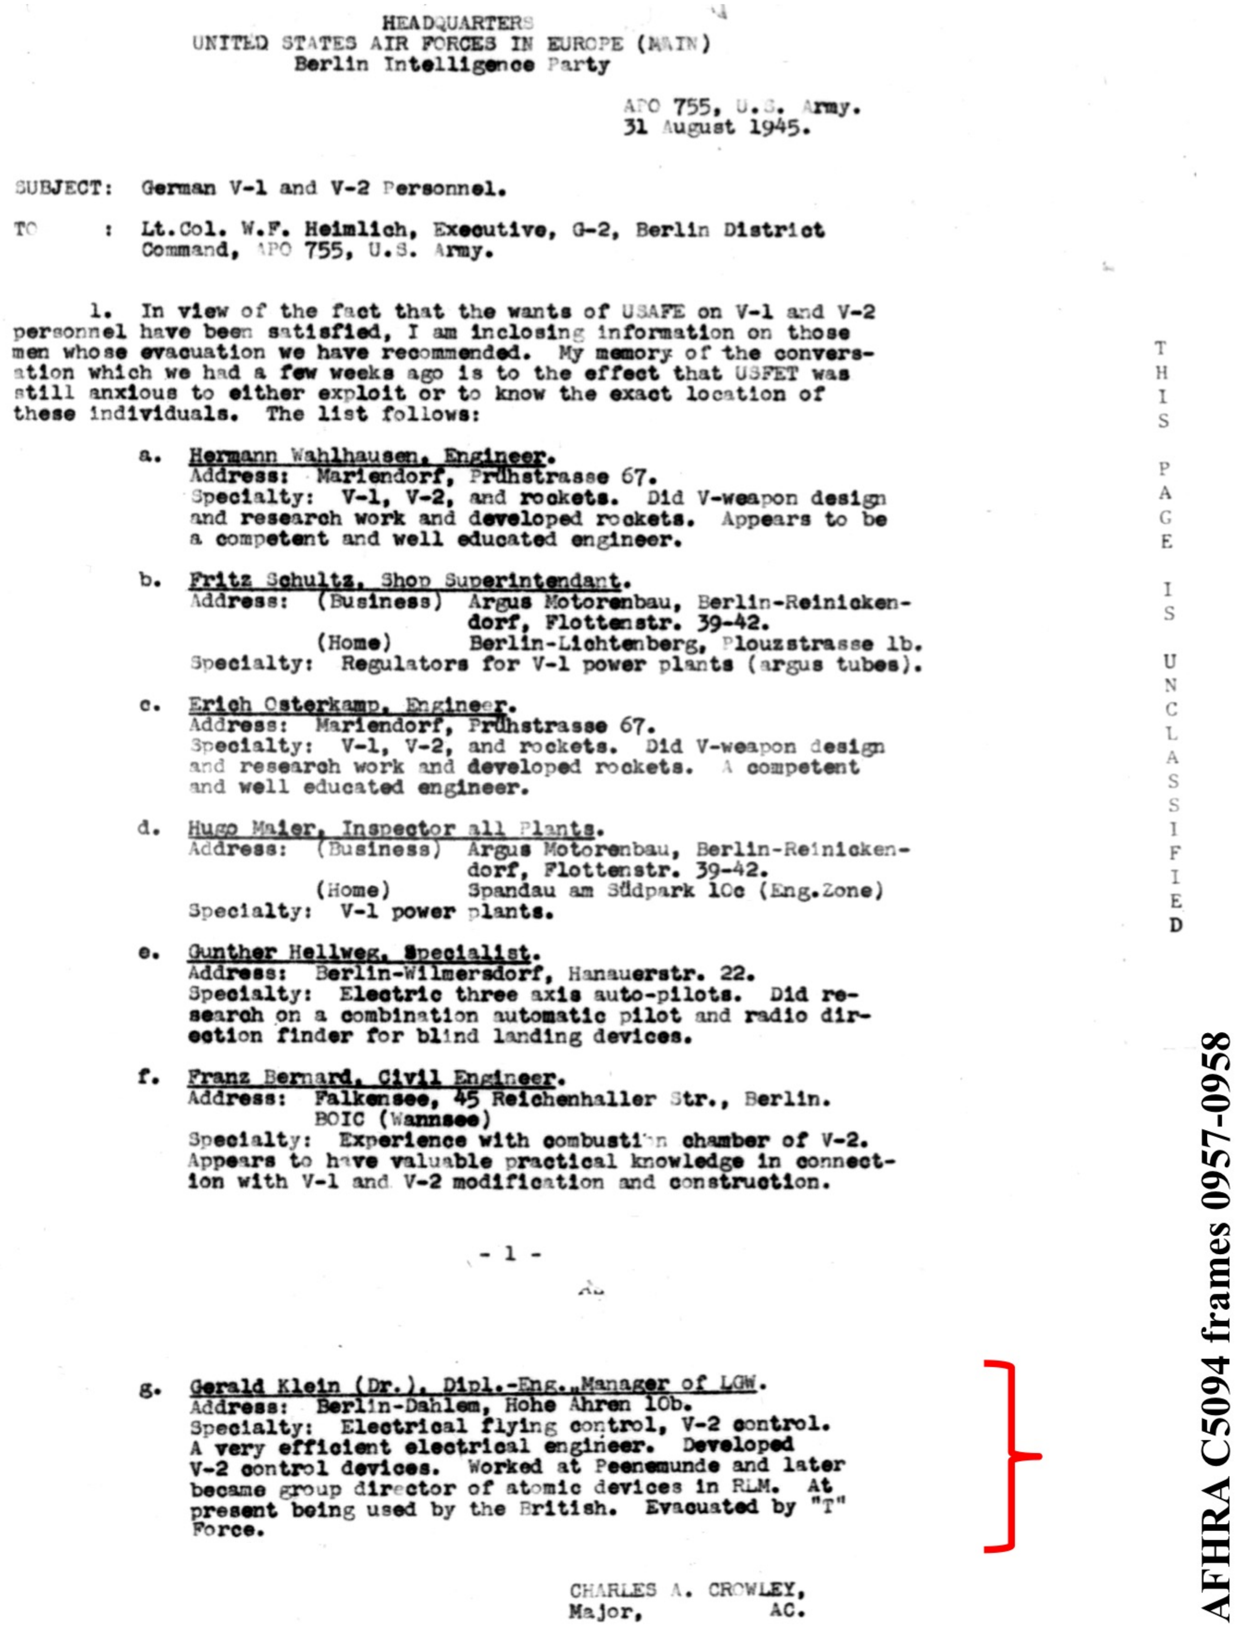
[...] g. Gerald Klein (Dr.), Dipl.-Eng., Manager of LGW.
Address: Berlin-Dahlem, Hohe Ähren 10b.
Specialty: Electrical flying control, V-2 control. A very efficient electrical engineer. Developed V-2 control devices. Worked at Peenemünde and later became group director of atomic devices in RLM. At present being used by the British. Evacuated by "T" Force.

[See document photo on p. 5020.

Dr. Gerald Klein was listed as the manager of "LGW," which was the Luftgerätewerk Hakenfelde A.G., part of the huge Siemens electrical company. If wartime Germany never had atomic devices or even serious plans to make them, as maintained by official histories, why did the RLM or Reichsluftfahrtministerium (Ministry of Aviation) have an entire group dedicated to atomic devices, of which Dr. Klein was the director? Note that Dr. Klein was evacuated by T-Force and "used by the British" after the war. Where are the reports on his interrogations? Where are the reports on his postwar work for the United Kingdom, or perhaps for other countries after that?

The Halstead Exploitation Centre is an example of a case where there seems to have been an especially large overlap between the interrogation of German-speaking scientists and collection of German-language reports on one hand, and the postwar development of British nuclear weapons on the other hand. See pp. 2127–2129 and 4166–4169. Just exactly what role did German-speaking scientists and information play in the British nuclear program?

The U.S. Army Air Forces officers writing and reading this memo seemed to casually understand what it meant that the Reichsluftfahrtministerium had an entire group on atomic devices, with no further explanation required in this memo. They also appeared to know about Dr. Klein from American interrogations of him. Where are the U.S. reports on American interrogations of Dr. Klein? Where are the U.S. reports explaining exactly what the atomic device group of the Reichsluftfahrtministerium was, what it accomplished during the war, and how it related to other nuclear-related work during the Third Reich?]



HEADQUARTERS
UNITED STATES AIR FORCES IN EUROPE (MAIN)
Berlin Intelligence Party

APO 755, U.S. Army.
31 August 1945.

SUBJECT: German V-1 and V-2 Personnel.

TO : Lt.Col. W.F. Heimlich, Executive, G-2, Berlin District Command, APO 755, U.S. Army.

1. In view of the fact that the wants of USAFE on V-1 and V-2 personnel have been satisfied, I am inclosing information on those men whose evacuation we have recommended. My memory of the conversation which we had a few weeks ago is to the effect that USFET was still anxious to either exploit or to know the exact location of these individuals. The list follows:

a. Hermann Wahlhausen, Engineer.
Address: Mariendorf, Prühstrasse 67.
Specialty: V-1, V-2, and rockets. Did V-weapon design and research work and developed rockets. Appears to be a competent and well educated engineer.

b. Fritz Schultz, Shop Superintendant.
Address: (Business) Argus Motorenbau, Berlin-Reinickendorf, Flottenstr. 39-42.
(Home) Berlin-Lichtenberg, Plouzstrasse 1b.
Specialty: Regulators for V-1 power plants (argus tubes).

c. Erich Osterkamp, Engineer.
Address: Mariendorf, Prühstrasse 67.
Specialty: V-1, V-2, and rockets. Did V-weapon design and research work and developed rockets. A competent and well educated engineer.

d. Hugo Maier, Inspector all Plants.
Address: (Business) Argus Motorenbau, Berlin-Reinickendorf, Flottenstr. 39-42.
(Home) Spandau am Südpark 10c (Eng.Zone)
Specialty: V-1 power plants.

e. Gunther Hellweg, Specialist.
Address: Berlin-Wilmersdorf, Hanauerstr. 22.
Specialty: Electric three axis auto-pilots. Did research on a combination automatic pilot and radio direction finder for blind landing devices.

f. Franz Bernard, Civil Engineer.
Address: Falkensee, 45 Reichenhaller Str., Berlin.
BOIC (Wannsee)
Specialty: Experience with combustion chamber of V-2. Appears to have valuable practical knowledge in connection with V-1 and V-2 modification and construction.

- 1 -

g. Gerald Klein (Dr.), Dipl.-Eng., Manager of LGW.
Address: Berlin-Dahlem, Hohe Ahren 10b.
Specialty: Electrical flying control, V-2 control. A very efficient electrical engineer. Developed V-2 control devices. Worked at Peenemunde and later became group director of atomic devices in RLM. At present being used by the British. Evacuated by "T" Force.

Nazis Really Had Atom Bomb Almost Ready. *Baltimore Sun.* 8 August 1945, p. 4.

London, Aug. 7 (AP)—Allied sabotage and bombing of experimental stations and plants along the Baltic coast and in southern Norway upset a German timetable to use atomic bombs against Britain last spring, an authoritative informant said today.

"But Nazi scientists had been carrying out experiments along this line for many years and if the war had not ended when it did they likely would have been able to launch attacks," said the informant, who throughout the war maintained contact with underground sources inside Germany.

He said the German super weapon was labeled the V-3 and was planned to follow the softening up work done by the V-1 and V-2.

[This AP story was also carried by other newspapers, for example:
Nazis Planned to Use Atomic Bombs. *Daily Colonist* (Victoria, Canada). 8 August 1945, p. 8.
https://ia800207.us.archive.org/0/items/dailycolonist0845uvic_5/dailycolonist0845uvic_5.pdf]

Future of the Atomic Bomb: Power for Peace or Chaos. *U.S. News.* 17 August 1945, pp. 20-23. www.usnews.com/cmsmedia/94/76/07545cb1465e8d8f022bea2bfc5d/19450817-future-of-the-atomic-bomb-power-for-peace-or-chaos.pdf

The Germans had planned to use the atomic bomb in the warhead of a V-type winged torpedo such as they fired upon England across the Channel. With such a bomb, they might have devastated England. [...]

At the moment, the only defense that military men can think of is to destroy the source of production for atomic bombs. High officials recognize that, if such a weapon were put into the hands of a madman like Hitler, civilization could be destroyed or held in pawn at will.

Awesome Force of Atom Bomb Loosed to Hasten Jap Surrender. *Newsweek.* 13 August 1945, p. 30.

On Sunday morning, August 5 (Washington time), an American airplane flew over Hiroshima, a Japanese army base on the Inland Sea. It dropped a single, small bomb. [...]

Thus the Allied nations had won what the President called "The Battle of the Laboratories" against the Axis. [...]

Metal of the Millennium: German scientists nearly succeeded in solving it. Since the surrender of the Nazi armies, Allied officers have revealed that Germany would have been able to strike with atomic bombs by January 1945, if the invasion had not come six months before. The highest Allied officials knew that such explosives could have won the war for the Axis.

The United States had begun research on them in late 1939. [...]

[This is an astounding public admission that the German nuclear weapons program existed, was actually ahead of the U.S. nuclear program, and drove the timetable for the Allied invasion of Europe during the war. See p. 5010. See also p. 5031 for a very similar admission from General George Marshall, the Chief of Staff of the U.S. Army, in his final public report on the war. That same fact was confirmed by a formerly Top Secret U.S. CIC document on p. 4411, paragraph 15. See also the written statement of Col. George Woods on p. 5073.

What is the true history of the German programs for developing nuclear weapons as well as methods to deliver them to Allied targets? What is the true history of Allied knowledge about those programs, both during and after the war? Where is all of the corresponding evidence stored now?]

Press release, Office of War Information, Franklin-2994, NB-3297, Technical Industrial Intelligence Committee. 25 August 1945. [NARA RG 40, Entry 75, Box 62 (Old 158); NARA RG 208, Entry 198, Box 1042]

Germany's inner war secrets ranged from experiments with the atomic bomb, anti-radar devices, and piloted rocket missiles that they expected to cross the Atlantic in 17 minutes, to butter made from coal, the Office of War Information reported today. [...]

CIOS teams combed Germany for Germany's hidden secrets on weapons, oil production, raw materials, synthetics, new engineering and chemical processes, inventions, patents, finance, economics, and German machinations in the political field.

Already more than 2,000 visits to German "intelligence targets" have been made by CIOS and 3,000 preliminary assessment reports have filtered through military channels to Washington, where they are made available to appropriate agencies. The agencies are authorized to translate the findings into projects useful to the allied cause and for post-war purposes.

Many of the German secrets, at the time CIOS uncovered them were considered of great potential value in the war against Japan and many of them were being adopted for use in the Pacific when the war ended. However, they are also of real value in the long-range control of Germany and also will facilitate technological advances in many industrial fields in peacetime, OWI reported on the basis of information provided by military authorities.

The secrets, it is conservatively estimated, would have saved the Allies many millions of dollars for research and scientific development, if the war had continued to the end of 1945 or longer. They indicate that German invention was far ahead of her capacity to translate theory into industry. The rapid advances of the Allied armies prevented her from putting into practice many of the technological advances evolved in the laboratories of her scientists. These same secrets, in some cases may shortly make some American technical processes obsolete and outmoded.

While German Government files yielded many of the secrets, the intelligence teams, which began to go into action on the heels of General Eisenhower's troops, soon after D-Day, often found vital clues through casual conversation with individuals, through close observation of physical facilities of war plants, in interviews with technical personnel and through meticulous and thorough search for hidden documents. [...]

Some of the more startling of the secrets that may be disclosed at this time, show that not only had Germans made significant progress in the development of an atomic bomb and in the production of "heavy water" but they:

1. Had contemplated a piloted missile with a possible range of 3,000 miles. The designer envisaged commercial applications for trans-Atlantic passenger crossing in 17 minutes.

2. Were working on a formula for new war gases that they hoped would prove more deadly than any chemical agent yet developed.

3. Had specifications and construction details for naval vessels of advanced design, including submarines with high underwater speeds and apparatus for sustained underwater operations.

4. Had developed a system of radar camouflage consisting of anti-radar coverings and coatings to be employed on submarines and other weapons.

5. Had highly advanced jet engine, rocket assisted take-off and aero-dynamics designs.

6. Had found new uses for many staples, as for example, coal. From coal the Germans were making a synthetic butter as well as alcohol of both beverage and industrial types, aviation lubricants, soap, and gasoline.

7. Had designs for various secret types of guns and gun sights, novel gear and transmission construction and air-cooled diesel engines.

Other German war secrets ranged from records on the location of German capital in neutral countries, and the status and composition of German cartels, to specifications of long-range rocket developments that scientists describe as “sensational.” In addition to the missile that they expected to have a range of 3,000 miles, the Germans had plans for V-type weapons much more advanced than those which they directed against the British Isles last year. [...]

The numerous German medical and pharmaceutical developments included the production of a “froth” clothing compound. This was designed to insulate and protect aviators lost in arctic waters.

Although many of the synthetics devised by the Germans are pronounced inferior to American products, a number of others are highly advanced. Processes used in their synthetic rubber industry, for example, are being made available to United States war manufacturers.

Similarly, synthetic gasoline and lubricants provide important keys for United States industry; some of the German methods already have been made available to United States produces, and will result in improved products for peacetime use.

Gasoline from coal, eventually to cost little more than the standard petroleum product of today, is also a possibility based on a German war formula. Technological improvements that may result from adaptation of the techniques in United States plants, scientists say, may make this and many other products envisioned by the Germans highly practical from a commercial standpoint.

Designs of long-range German smooth-bore guns that fire rocket-assisted finned projectiles, a “squeeze” gun that obtained higher velocities and longer range through use of a tapered bore, a device for reducing the wear on gun barrels, and data on the substitution of steel cartridge cases for both small and large calibre weapons (thus reducing requirements for copper and other critical materials), are now Allied possessions. Still other German developments range from improved acoustic, magnetic and non-magnetic anti-tank and anti-personnel mines to the use of salt water in electric torpedo propulsion. [...]

CIOS investigations were carried out in the field in two ways. First, Combined Advanced Field Teams, groups of technically qualified men who followed the combat forces, gave a rapid preliminary assessment of the technical value of the targets. More than 200 expert United States and British assessors were continuously in the field during the period of rapid military advance.

Second, following up plans already made and the reports coming back from the assessors, teams of expert scientists and technologists carried out detailed investigations. The number of such visits by July 1945 had exceeded 2,000.

Both the assessments and the investigations were carried out by teams, combining U.S. and British representatives. Government leaders, scientists, industrialists, economists and historians were represented in the groups. The small teams, each made up of experts in a particular field, were attached to the intelligence staff of all the major army commands on the Western Front.

Some of the industrial fields covered were: aeronautics, automotive production, building materials, chemicals, communications, food, forest products, general industrial equipment, liquid fuels and lubricants, machinery, medical wares, metals and materials, railroad equipment, rubber, safety and technical equipment, shipbuilding, solid fuels, textiles and utilities. [...]

The German processes, it was realized, not only would reduce research work in British and United States laboratories, releasing them for other scientific ventures, but would save millions of man-hours in war production and on the fighting fronts and, additionally, might alleviate shortages of some types of war materials. [...]

[See document photos on p. 5026.

The U.S. Office of War Information publicly stated that Germany had conducted "experiments with the atomic bomb," which is an extraordinary statement that cannot (or at least should not) be ignored.

This Office of War Information press release, as well as any related discussions of reporters with officials, prompted numerous newspaper articles such as the following examples, which stated, "The Germans... had reached the experimental stage with the devastating atomic bomb," "an atomic bomb, on which... the Germans had made considerable progress," and "Not all the secrets have been disclosed."]

James E. Chinn, Nazis Almost Had Rocket for Atlantic Hop. *Washington Post.* 27 August 1945.

God blessed America.

Just before the European war ended the Nazis were experimenting with a piloted rocket missile designed to span the Atlantic in 17 minutes, the Office of War Information revealed yesterday as it unveiled a variety of Germany's inner war secrets.

The Germans also, according to OWI, had reached the experimental stage with the devastating atomic bomb, devices to destroy the sight of the all seeing eyes of radar, and new war gases they hoped would prove more deadly than any chemical agent yet developed. And that's not all.

OFFICE OF WAR INFORMATION

ADVANCE RELEASE:
Not for use by Press or Radio before
7 P.M., EWT, Sunday, August 26, 1945

Germany's inner war secrets ranged from experiments with the atomic bomb, anti-radar devices, and piloted rocket missiles that they expected to cross the Atlantic in 17 minutes, to butter made from coal, the Office of War Information reported today.

How these German war secrets began to be unlocked by American and British experts long before V-E Day was officially revealed today. The announcement included a statement on the scope and value of some of the secrets disclosed. Many of them were being adapted by United States and British technologists for use against the Japanese when the war ended, OWI reported. The thoroughness of the search for German war secrets foreshadows a similar probe for the secrets now locked in Japan, OWI added.

Some of the more startling of the secrets that may be disclosed at this time, show that not only had the Germans made significant progress in the development of an atomic bomb and in the production of "heavy water" but they:

1. Had contemplated a piloted missile with a possible range of 3,000 miles. The designer envisaged commercial applications for trans-Atlantic passenger crossing in 17 minutes.

2. Were working on a formula for new war gases that they hoped would prove more deadly than any chemical agent yet developed.

3. Had specifications and construction details for naval vessels of advanced design, including submarines with high underwater speeds and apparatus for sustained underwater operations.

4. Had developed a system of radar camouflage consisting of anti-radar coverings and coatings to be employed on submarines and other weapons.

5. Had highly advanced jet engine, rocket assisted take-off and aero-dynamics designs.

6. Had found new uses for many staples, as for example, coal. From coal the Germans were making a synthetic butter as well as alcohol of both beverage and industrial types, aviation lubricants, soap, and gasoline.

7. Had designs for various secret types of guns and gun sights, novel gear and transmission construction and air-cooled diesel engines.

Other German war secrets ranged from records on the location of German capital in neutral countries, and the status and composition of German cartels, to specifications of long-range rocket developments that scientists describe as "sensational". In addition to the missile that they expected to have a range of 3,000 miles, the Germans had plans for V-type weapons much more advanced than those which they directed against the British Isles last year.

NARA RG 40,
Entry UD-75, Box 62

Figure D.996: Excerpts from press release, Office of War Information, Franklin-2994, NB-3297, Technical Industrial Intelligence Committee. 25 August 1945 [NARA RG 40, Entry 75, Box 62].

17-Minute Oversea Rocket Plane Among Germany's War Secrets. *New York Times.* 27 August 1945 p. 10.

American and British technicians, closely and quickly following the Allies' military advances across France and Germany, have taken possession of a wealth of information about German "secret weapons" on which the enemy counted so much but that he did not have time enough to develop.

Besides an atomic bomb, on which, as has been made known, the Germans had made considerable progress, German scientists and engineers had developed a defense against radar and experimented on piloted rocket missiles that it was thought would be capable of crossing the Atlantic in seventeen minutes. These and many other German war secrets were disclosed today by the Office of War Information in reporting on the operations of a combined American and British intelligence organization that made daring forays on targets containing vital war information. [...]

They concentrated on the "targets" believed to be richest in vital information on weapons, oil production, raw materials, synthetics, new engineering and chemical processes, inventions, patents and machinations in finance, economics and politics.

More than 2,000 missions to such "targets" have already been made, and the information obtained was estimated by the receiving authorities as being worth "millions of dollars" in research and scientific development. The findings indicated, the OWI reported, that "German invention was far ahead of her capacity to translate theory into industry.

The rapid advances of the Allied armies prevented her from putting into practice many of the technological advances evolved in the laboratories of her scientists," the OWI said. It added that some of the unlocked secrets might soon make some American technical processes "obsolete and outmoded."

Some Secrets Unrevealed

Not all the secrets have been disclosed, but the most startling ones were said to pertain to the development of the atomic bomb and the production of "heavy water," used in one method of making the bomb. The defense against radar was a system of radar camouflage consisting of anti-radar coverings and coatings. It would be employed, presumably, on submarines and other weapons.

The Germans contemplated a piloted missile with a possible range of 3,000 miles. The designer envisioned for it a commercial application for flying passengers across the Atlantic in a little more than a quarter hour.

[Also reported in:

The Times (London). 27 August 1945.

Nazis Had 10,000 mph Atom Plane—In Theory. *Eighth Army News.* 28 August 1945.]

***Interview with Brig. Gen. Thomas J. Betts by Dr. Maclyn Burg, Oral Historian.* 18 October 1973. Dwight D. Eisenhower Library. pp. 277–289, 294–295, 297–298. https://www.eisenhowerlibrary.gov/sites/default/files/research/oral-histories/oral-history-transcripts/betts-thomas.pdf**

BETTS: Well, we got to this office of Stalin's, which was a long, narrow room with a rather small desk at one end. And between the desk and the door was a long, green beige-covered table. And there was Stalin. He came to see us, very pleasantly, and his first remark was, "Well, I'm happy to tell you that I responded to your pleas and have started an offensive to take the pressure off you in the Bulge." [...A]t the onset of the Bulge, Churchill had sent a personal message to Stalin saying, in effect, "We're in dire peril and will you please exert all possible pressure on the eastern front until we solve this Bulge problem." [...I]t took us from the 1st of January to the 14th to get to the Kremlin. [...]

BURG: So he was not alone in the room when you entered.

BETTS: No, he had an interpreter and he had a General [A.I.] Antonov, A-n-t-o-n-o-v[....] Who was the deputy chief of staff. The chief of staff, I think, at that time was—I think it was Malenkov, but I'm not sure. But the story in Russia, in Moscow, at the time was that the way Stalin really ran the war was that he sent the chief of staff out to inspect the armies and the army groups and shoot whatever generals were necessary, and Antonov was the office man who kept the papers going and worked out the policy. Stalin himself, apparently, did not inspect troops. He did not go out to the front. [...]

BURG: [...] Now was Air Marshal Tedder, in effect, presenting the allied case?

BETTS: [...] Tedder then just made the pitch that I described at the beginning here: mainly, that we were hoping that—we were expecting to close the Rhine, of course, in March—and we were hoping that even if the Russians could not put on an offensive at that time, that they would create enough of a disturbance so that the Germans would not reinforce the front. And Stalin shook his head and agreed. He said that they, that he understood, that, in effect, they had already started their offensive, which they had. They had started on the, I think the 13th or 14th, and at that time their armies were well into Poland. They had not reached German soil yet anywhere.

[Stalin and General Antonov were the recipients of the very best Soviet intelligence on the German nuclear weapons program (4481–4493). In particular, by the time of this January 1945 meeting they had already received the November 1944 intelligence report on p. 4481.]

General Thomas J. Betts appears to have played an important role in many world events from the 1920s through at least the 1950s, and he deserves far more study from historians than he has received. For the barest overviews, see:

> https://www.washingtonpost.com/archive/local/1977/05/26/retired-army-officer-served-in-intelligence/aac29316-adc0-469d-b194-c015297f360e/
>
> https://generals.dk/general/Betts/Thomas_Jeffries/USA.html

Since August 1944, General Betts had been the chair of the Combined Intelligence Objectives Subcommittee (CIOS) in charge of investigating and transferring Germany's most advanced technologies. He was also the Assistant Chief of Staff for Intelligence (G-2) at Supreme Headquarters Allied Expeditionary Forces (SHAEF) under Eisenhower. He appears to have been closely connected to the OSS and continued to work for the CIA until at least 1958. Thus he was in ideal positions to receive the best western Allied intelligence on the German nuclear weapons program. Indeed, he wrote some astonishing details about the German program to develop nuclear weapons and delivery vehicles for them (p. 5030) while admitting that some information could not be publicly disclosed, and he concluded that the U.S. Alsos Mission had failed to properly investigate that program (p. 3287).

The fact that someone with the position and knowledge of General Betts was sent all the way to Moscow to meet with Stalin and Antonov in January 1945 is truly extraordinary, and virtually unknown apart from his remarks in this obscure interview. From Betts's description of his mission, the U.S./U.K. and the Soviet Union were desperate to overrun German territory as soon as possible. At the very least, the U.S./U.K. intelligence and the Soviet intelligence on the German nuclear program would have been an unstated yet fundamental motivation for that strategy and for the meeting. Is there any archival evidence that something actually was stated, that the U.S./U.K. and the Soviet Union shared any intelligence on the German program during this January 1945 meeting or in other ways and times?

What more did General Betts learn about wartime German work when he served as the U.S. military attaché in Poland after the war, and in his other postwar positions?]

R. P. Linstead and T. J. Betts. 15 September 1945. ***The Intelligence Exploitation of Germany. Report of Combined Intelligence Objectives Subcommittee.*** **G-2 Division, SHAEF. Ch. 4, pp. 37, 47–51. [AFHRA A5186 electronic version pp. 904–1026]**

Certain items have been omitted because of security considerations. [...]

United States and British specialists have obtained complete information covering all German directed missiles from the pioneer model "A sub-o", which employed oxygen and alcohol fuel in attaining a range of 18 miles, to the latest model of the A-9 which was capable of a 3400 mile per hour speed and a range of 2400 miles. The A-9 was an improved development of the V-2 or A-4, and was equipped with wings thereby enabling it to level off at a height of 70,000 feet. One model of this missile was equipped with a Lorin tube which provided propulsion at the peak of the trajectory, the missile was expected to result in a maximum range of 2400 miles. Other variations of this model were capable of attaining altitudes 60 miles above the earth's surface and speeds in excess of 7300 feet per second. Improved radio controls were developed to supercede the "integrating accelerometer" used in early V-weapons. Some measure of the accuracy which could be achieved with these controls is evidenced by the fact that the radio controlled models were capable of an accuracy of plus-or-minus 150 feet in contrast to a plus-or-minus 50 mile error inherent in the V-2.

German scientists engaged in directed missiles envisaged important commercial applications of the long range missile. Experiments had already been conducted on piloted models. Missiles capable of trans-Atlantic crossings in approximately 40 minutes were found on design boards and scale models were undergoing wind tunnel tests. Amazing performances were considered practical because of the lessened atmospheric resistance and gravitational pull in stratospheric regions. [...]

Of particular significance were the statements, made by German experts in the rocket and controlled missile field, that much of the priority accorded their work by the German High Command was in anticipation of the use of atomic explosives. These authorities stated that KWI had repeatedly assured Hitler that an atomic explosive would be available for use within a comparatively short time. During the last months of work by the Peenemünde staff, V-weapons were designed with much smaller war-heads. Quite possibly this trend was in anticipation of the successful development of a German atomic explosive.

[See pp. 5446–5447 for photos.

This report was written by the CIOS chairs, U.S. General Thomas Jeffries Betts, Deputy G-2 of SHAEF (pp. 3287, 5028–5029), and U.K. Ministry of Supply chief advisor and F.R.S. Professor Reginald Patrick Linstead. Based on specific discoveries by their CIOS investigators, these high-ranking officials reported that "the latest model of the A-9 ... was capable of a 3400 mile per hour speed and a range of 2400 miles," and that "experiments had already been conducted on piloted models." That statement sounds like a description of completed hardware, not a mere drawing board design. What specific hardware and information were discovered that are not discussed in the presently unclassified reports? Can any reports that are still classified be located and released?

The CIOS chairs also reported that Hitler, the German High Command, and the leading experts in the rocket programs had been "repeatedly assured ... that an atomic explosive would be available for use within a comparatively short time." Thus the CIOS chairs contradicted the public statements of the Alsos Mission and confirmed that there was indeed a German program to develop an atomic bomb, and that it was far more than a paper design program—its hardware had passed through sufficient development, production, and testing by the end of the war that it was ready or nearly ready to be used in combat.]

General George C. Marshall. 1 September 1945 (publicly released 10 October 1945). Third and Final Biennial Report to the Secretary of War. In George C. Marshall. 1996. *Biennial Reports of the Chief of Staff of the United States Army to the Secretary of War: 1 July 1939–30 June 1945.* Washington, D.C.: U.S. Government Printing Office. pp. 132, 210. https://history.army.mil/html/books/070/70-57/CMH_Pub_70-57.pdf

Victory in this global war depended on the successful execution of OVERLORD. That must not fail. Yet the Japanese could not be permitted meanwhile to entrench in their stolen empire, and China must not be allowed to fall victim to further Japanese assaults. Allied resources were searched through again and again, and strategy reconsidered in the light of the deficiencies. These conclusions seemed inescapable: France must be invaded in 1944, to shorten the war by facilitating the advance westward of the Soviet forces. At the same time German technological advances such as in the development of atomic explosives made it imperative that we attack before these terrible weapons could be turned against us. In addition, the pressure on the Japanese in the Pacific must not be relaxed. Communications with China must be reopened. Resources were allocated accordingly. The balance was extremely delicate but we had to go ahead. [...]

Between Germany and America in 1914 and again in 1939 stood Great Britain and the USSR, France, Poland, and the other countries of Europe. Because the technique of destruction had not progressed to its present peak, these nations had to be eliminated and the Atlantic Ocean crossed by ships before our factories could be brought within the range of the enemy guns. At the close of the German war in Europe they were just on the outer fringes of the range of fire from an enemy in Europe. Goering stated after his capture that it was a certainty the eastern American cities would have been under rocket bombardment had Germany remained undefeated for two more years. The first attacks would have started much sooner. The technique of war has brought the United States, its homes and factories into the front line of world conflict. They escaped destructive bombardment in the second World War. They would not in a third.

[See also p. 5022 for a very similar public admission.

The same facts were confirmed by a formerly Top Secret U.S. CIC document on p. 4411, paragraph 15.

See also the written statement of Col. George Woods on p. 5073.

George Marshall was the Chief of Staff of the U.S. Army during World War II, responsible for the overall conduct of the war in both Europe and the Pacific. From that lofty position, he received reliable intelligence that:

1. "German technological advances such as in the development of atomic explosives made it imperative that we attack before these terrible weapons could be turned against us," thus necessitating his decision to launch Operation Overlord in early June 1944. The statement and decision suggest a potential timeline:
    (a) The United States received intelligence reports of an advanced German nuclear weapons program no later than late 1943.
    (b) Those intelligence reports indicated that Germany could have a functional nuclear weapon as soon as summer or autumn 1944.

2. “At the close of the German war in Europe,” American cities “were just on the outer fringes of the range of fire from an enemy in Europe.” That statement suggests that:
    (a) No later than April 1945, Germany had developed one or more methods of delivering a payload to the United States: intercontinental jet bombers, intercontinental ballistic missiles, and/or submarine-launched missiles.
    (b) No later than April 1945, Germany had developed a payload so destructive that it justified the enormous expense of delivering it to the United States: presumably a nuclear weapon.

Where did Marshall’s wartime intelligence come from? Where are those reports now?

What did the United States discover after the war that apparently confirmed that intelligence? Where are those reports and any collected materials now?

Marshall’s statements suggest that there were profound reasons behind the ways that Germany and the Allies prosecuted the war that have been omitted from history books ever since.

Marshall’s statements also appear to contradict the public conclusions of the Alsos Mission.]

George C. Marshall. Text of Marshall’s Address Warning of Peril in Loss of Concept of World Responsibility. *New York Times* 30 October 1945 p. 6.

In the current emotionalism of the hour we turn for relief from positive action to new theories, new discoveries—the supersonic rocket, of atomic power or explosion. If these remarkable products of our science are merely to turn us from action to inaction on one plea, one theory or another, they may well have a more tragic influence on the destiny of the United States than the most pessimistic fear they will have on civilization. I have been considering the military ramifications of atomic explosion for more than two years, since my job placed me in the middle of the grim race toward this scientific power. I think I have—if only because of my head-start—spent much more time than most Americans thinking about such bombs and what they will mean to military operations as well as to civilization at large.

I cannot escape the conclusion that the possibilities of atomic explosion make it more imperative than ever before that the United States keep itself militarily strong—and use this strength to promote cooperative world order.

No one can foresee unerringly into the future but it is not hard to predict that supersonic atomic rockets will have a profound influence on any war that ever again has to be fought. But, rather than decrease the necessity for our preparation, both in manpower and materiel, this terrible new weapon will tremendously increase it.

The present public apathy regarding our military obligations for the future comes as no surprise to me. [...]

Eisenhower to See Bomb: He Tells California Group He Will Watch Tests in Pacific. *New York Times.* 23 February 1946 p. 14.

Gen. Dwight D. Eisenhower, Army Chief of Staff, will witness the atomic bomb tests in the Pacific in May[...]

There was no thought of using the atomic bomb on Germany, General Eisenhower said.

"My main concern was that the Germans did not get the atomic bomb to use on us," he asserted.

Dwight D. Eisenhower. 1948. *Crusade in Europe.* Ch. 13–14, pp. 229, 258–260.

Alarming Intelligence reports concerning the progress of the Germans in developing new long-range weapons of great destructive capacity also indicated the advisability of attacking [launching D-Day] early.

From time to time during the spring [1944] months staff officers from Washington arrived at my headquarters to give me the latest calculations concerning German progress in the development of new weapons, including as possibilities bacteriological and atomic weapons. These reports were highly secret and were invariably delivered to me by word of mouth. I was told that American scientists were making progress in these two important types and that as a result of their own experience they were able to make shrewd guesses concerning some of the details of similar German activity. All of this information was supplemented by the periodic reports of Intelligence agencies in London. In addition, aerial photographs were scrutinized with the greatest care in order to discover new installations that would apparently be useful only in some new kind of warfare.

The finest scientific brains in both Britain and America were called upon to help us in evaluation and in making estimates of probabilities. Our only effective counteraction, during the preparatory months of 1944, was by bombing. We sent intermittent raids against every spot in Europe where the scientists believed that the Germans were attempting either to manufacture new types of weapons or where they were building launching facilities along the coast.

During this long period the calculations of the Intelligence agencies were necessarily based upon very meager information and as a consequence they shifted from time to time in their estimates of German progress. Nevertheless, before we launched the invasion, Intelligence experts were able to give us remarkably accurate estimates of the existence, characteristics, and capabilities of the new German weapons.

[...]

On June 12, 1944, the first flying bomb, known as V-1, reached London. The V-1 [...] contained a large amount of explosive which detonated upon contact, and the blast effect was terrific. The first V-2 was not used until early August. [...]

The V-2 bomb was particularly destructive when it fell directly into a structure of some kind. Owing to its speed, it penetrated deeply into the ground and its great explosive effect was exerted directly upward. As a consequence, when it fell into open spaces it was relatively ineffective, but so great was its explosive charge when it hit a building that destruction was almost complete.

The development and employment of these weapons were undoubtedly greatly delayed by our spring bombing campaign against the places were we suspected they were under manufacture. Peenemünde, in Germany, was known to be one of the largest of the German experimental plants and periodically we sent large formations of bombers to attack that area. There were other places indicated to us as suspicious. One was Trondheim, in Norway, where we thought that the Germans were engaged in atomic development. We also bombed the suspected launching sites along the coast of northwestern Europe, where our reconnaissance photography showed numerous facilities and installations that could not be interpreted in terms of any known weapon. These areas were continuously hammered.

The effect of the new German weapons was very noticeable upon morale. [...]

It seemed likely that, if the German had succeeded in perfecting and using these new weapons six months earlier than he did, our invasion of Europe would have proved exceedingly difficult, perhaps impossible. I feel sure that if he had succeeded in using these weapons over a six-month period, and particularly if he had made the Portsmouth-Southampton area one of his principal targets, Overlord might have been written off.

[Eisenhower's statements seem to agree with Marshall's statements about the very real and very urgent nuclear danger from Germany.

According to Eisenhower, U.S. intelligence information about the German nuclear program was so secret that it was only given to him in oral presentations, not in writing. That can help explain the absence of surviving documents in U.S. archives. Just how much did top U.S. intelligence officials know about the German nuclear program, and how did they know it? The time period that Eisenhower described was in early-mid 1944, long before the Alsos Mission, which in any event reported negative findings.

What German nuclear weapons development was being conducted at Trondheim? According to official histories, the only significant nuclear-related work in Norway was heavy water production in the Vemork area (pp. 4027–4041), but that was hundreds of kilometers to the south of Trondheim, so it seems unlikely that Eisenhower confused the two locations. For another report of German nuclear weapons development in Norway, see p. 5011. For two other sources that may be related, see pp. 4436 and 4404.]

Army To Use V-2 Bombs To Test Radar As Atom-Rocket Defense. *New York Times.* 1 March 1946 p. 1.

WASHINGTON, Feb. 28—The Army Air Forces disclosed today that it was seeking a means of protecting the United States against possible future atomic bombardment by experimenting with techniques for radar detection of captured German V-2 rockets.

Brig. Gen. William L. Richardson, chief of the Air Staff's Guided Missiles Division, explained that the idea was to devise a means of detecting and "tracing" by radar the enemy rockets as they came whizzing through the stratosphere at 3,000 miles an hour. [...]

General Richardson said that it was important that a means be found "as quickly as possible" to defend the United States against "a sudden enemy rocket attack."

He stated that the Air Forces had been working on rocket defense since 1943, and also stressed that, through the recently activated First Experimental Guided Missiles Group, it was conducting "extensive research" in offensive uses of rockets.

[General Richardson's desperation to find a means "as quickly as possible" to defend against "a sudden enemy rocket attack" by nuclear-armed German rockets suggests that some other nation already had that capability. Did he know that Germany had already developed that capability, prompting him to worry that German engineers would confer that capability on the Soviet Union?

The next article strongly suggests that General Richardson did indeed know that wartime Germany had developed, or at least nearly finished developing, both nuclear weapons and intercontinental rockets capable of carrying them.]

Reveal Nazis Planned Rocket to Blast N.Y. at 6000 MPH. *Indianapolis Times.* 2 August 1947, p. 4. https://newspapers.library.in.gov/?a=d&d=IPT19470802.1.4

A-9 Was Designed to Employ Booster Weighing 190,000 Pounds for Acceleration

By Science Service

WASHINGTON, Aug. 2—The Germans planned a bomb to cross the Atlantic and blast New York. It was a rocket to be started on its long journey by another rocket which detached itself when its job was done.

This was revealed today by Brig. Gen. William L. Richardson of the U.S. Army Air Forces.

Gen. Richardson, chief of the A.A.F. Guided Missiles and Air Defense Division, spoke as a guest of Watson Davis, director of Science Service, on "Adventures in Science," heard over the Columbia network.

The Germans, he said, developed several rockets known as the "A" series. The V-2, used against London, was one of these. Although it was the only one of this series to be used operationally in the last war, it is not hard to visualize what might have been in store for the Allies had the Germans been given sufficient time to complete developments.

Acid Used in Fuel

Each of the “A” series was developed primarily for research, with the exception of the A-4, later known as the V-2. The A-10 was the end result toward which this whole program was directed. This is the weapon which the Germans expected to use in bombing New York.

The A-10 was described by him as a booster rocket placed behind the A-9, giving it two-step co-operation to secure ranges of 3000 miles. The A-9 was much like the A-4, more familiarly called the V-2, with wings added to give increased range and using acid as an oxidizer in its fuel.

The A-10 was never actually constructed. However, all design studies and computations had been completed. It appears that it could have been built and used if the Germans had been given another year of development and production.

Speed Put at 6000 M. P. H.

The total weight of the A-10 was to have been 190,000 pounds. The weapon was nearly 12 feet in diameter and 25 feet long. The 29,000-pound A-9 was to have been accelerated to a speed of 2500 miles per hour by the use of the A-10 as a launching rocket, which detached itself and would drop free after serving its purpose.

It was the A-9 that would reach the target. Its rocket motor would be turned on when the A-10 dropped. This would increase its speed to about 6000 miles an hour. It would have carried a warhead of about 2000 pounds. This is a payload of only 1 per cent of the starting weight of the weapon, but there is evidence to believe, he stated, that the Germans intended to utilize an atomic warhead which would have made this weapon extremely deadly.

[The same article was also published as:

> Nazis Planned Bomb to Blast New York. *Brooklyn Daily Eagle.* 2 August 1947, p. 3. https://bklyn.newspapers.com/image/52866650/

General William L. Richardson would have been a highly knowledgeable and very sober source for this information. For more information on him, see:

> https://www.af.mil/About-Us/Biographies/Display/Article/105809/major-general-william-l-richardson/

> https://media.defense.gov/2020/Apr/29/2002290975/-1/-1/0/200429-F-XX123-2007.JPG

As General Richardson would have known very well, it would take many years of large-scale work to go from the paper design of an intercontinental rocket to an operational and mass-produced system. Likewise it would have taken many years of work to go from the paper design of a nuclear weapon to a deployable nuclear warhead suitable for launching on the rocket. He told Science Service that Germany would have soon possessed both intercontinental rockets and nuclear warheads for them if the war had not ended when it did. Therefore he must have had considerable evidence that production and testing of intercontinental rockets and nuclear warheads were in the final stages when the war ended.

What evidence did General Richardson have, and where is that evidence stored now?]

Charlotte Knight. 1946. German Rocketeers: German Rockets and Guided Missiles Almost Won the War for the Nazis. *AAF Review* (July) 29:6:24–26, 48.

That the Allies won the war in Europe by a terrifyingly narrow margin is a fact now accepted by almost all military leaders who have seen at first hand Germany's progress in the guided missiles field. Just how narrow that margin really was will probably be a matter of considerable debate for a long time to come, but many guided missile experts who should know whereof they speak say that it was relatively small.

It was too close for comfort, and simply serves to underline even more emphatically the substantial edge the Nazis had in this field. Most Allied rocket experts will now concede that edge to have been at least a 10-year lead in the research and development of guided missiles. [...]

At war's end, in spite of her defeat, Germany's scientists and technicians had nevertheless left behind them at Peenemunde, Brunswick, Wiener Nieustadt and elsewhere the signposts of future air wars. From the captured results—some in production lines, some in stages of near-completion, and others on paper—we have since learned much that is enlightening, much that is disquieting. [...]

With the hindsight we now have as a result of our discoveries, several things become clear. One is that the Nazis' oft-repeated threats concerning the "secret weapons" they would shortly direct against the Allies were far from being purely "propaganda." Hitler had boasted that England and the whole world would soon feel their effect. Examination of Germany's missiles at war's end left very little doubt that Der Fuehrer had come uncomfortably close to making good his boast.

Also understandable now on the basis of our present knowledge is Germany's almost suicidal last-ditch stand after Allied forces had crossed the Rhine in overwhelming numbers. Assuming that the Nazis were completely whipped, the Allied populace could not understand why they would not give up and put an end to senseless, wholesale slaughter. But German commanders, it now appears, were aware that if they could hold out for just a short time longer they could very well effect at least a stalemate, if not a short-cut victory, on the European battlefront.

It is now also fairly generally known that the atomic bomb race was close—again, closer than we care to think about. And paralleling the Nazis' research on atomic explosives was their accelerated development of the V-2 program. Linking these two projects together makes credible another theory which is current among Allied guided missile groups: namely, that it was the intention of Nazi technicians to put some sort of atomic device in the warhead of the V-2.

This, they point out, would then have made the V-2s economical beyond question. One of the facts which has puzzled observers is that the V-2, with its small-sized warhead permitting only one ton of conventional explosives, did not justify the tremendous cost of each missile. The damage achieved—actually less than that of the V-1 which was many times cheaper and took only 800 man-hours to make—did not begin to compensate for the 12,950 man-hours required for the manufacture of every V-2. But if, as they now believe it had been originally planned, even a few of these supersonic V-2s could have carried atomic warheads, there is little doubt that they could have wiped our invasion ports off the map and reduced England to the shambles that are Nagasaki and Hiroshima.

It is thought that the only reason the Germans did resort to their uneconomical use of the V-2s with ordinary explosives is the obvious one that the atomic warhead devices simply were not yet ready, and Nazi military leaders, with their backs against the wall, were forced to throw at the Allies any weapon they had available, regardless of cost. Actually, however, the terrorizing effect of these 3,500 mph missiles—against which there was absolutely no defense—on London and Antwerp that winter of 1944–45 must certainly have made the Nazis feel that the V-2s had a psychological value alone far in excess of their actual dollars and cents cost for amount of damage inflicted.

Allied bombings of the Nazi heavy-water plants in Norway quite obviously retarded her atomic development, as did also the consistent sabotage on the part of many Norwegian scientists. But it is still a matter of scientific conjecture just how many weeks—or days—it might have taken Germany to be ready with her atomic devices for the V-2s.

And continue this same subject of Hitlerian threats, the Nazi claim that Germany had rockets which could bombard the US was not too far removed from actual achievement. Long-range missiles were in the design stage when Allied troops moved into Germany. Larger than the V-2s, these winged rockets, carrying smaller rockets which would take off on their own at a specific point, attain speeds up to 5,800 mph, and finish their trajectories in a long glide, were predicted to be capable of ranges up to 3,000 miles.

[...] Even now, more than a year after V-E Day it is still frightening to imagine what *might have* happened had we not halted Germany when we did. We now know that it was later than we thought. It is not enough to concede that the call was close unless, in that closeness, we have learned one of the war's most valuable lessons.

[This article was based on Donald Putt's March 1946 presentation (see p. 5472), as well as other information from him and from other Allied inspectors. Published in the official U.S. *Army Air Forces Review*, it stated that:

- German scientists had "at least a 10-year lead" over Allied countries in the field of guided missiles.
- Hitler's promised new secret weapons were not simply propaganda or paper designs, but missiles that were subjected to "examination... at war's end."
- At the war's end, the German military was fiercely defending territory that held those secret weapons in the expectation that they would be used.
- It was "fairly generally known that the atomic bomb race was... closer than we care to think about," and it was just a matter of scientific conjecture whether it was weeks or days that separated Germany from deploying rocket-launched nuclear weapons at the end of the war.
- These statements officially published by the U.S. Army Air Forces completely contradicted the claims of Samuel Goudsmit and the Alsos Mission that Germany was not even close to having nuclear weapons.

- In fact, this Army Air Forces publication seemingly admitted details that demonstrate the German nuclear program was many years ahead of the U.S. program. At the beginning of May 1945, the United States was still trying to complete its first fission bomb, and that weapon was so cumbersome that it would need to be delivered by a large plane. According to the Army Air Forces, by that time Germany apparently had multiple nuclear weapons ("rockets with nuclear warheads"), they were small enough to deliver via rockets, and Germany had developed suitable rockets with which they were integrated and on the brink of deployment. The United States would not reach that level of technology for over a decade—in the late 1950s—and even then only with large amounts of assistance from German-speaking scientists.

- "Almost all military leaders" accepted "that the Allies won the war in Europe by a terrifyingly narrow margin." This conclusion by contemporary observers best positioned to know all the facts is quite different than the conventional historical view that has been propagated for 75+ years.

- For many more references to nuclear-armed rockets that were intended to attack Allied targets during the war, see the list of documents on p. 5821.

Charlotte Knight, the author of this article, was a staff journalist who had been working full-time for the U.S. Army Air Forces for several years. She had flown around the world covering events during World War II, and she was the only woman to witness the Operation Crossroads fission bomb tests at Bikini Atoll from the air in 1946. Thus she would have written this article in a very sober fashion, without any embellishment, and exactly as Donald Putt and the Army Air Forces wanted it. For more information on Knight, see:

> Utah Woman Tells of Work with Air Force. *Deseret News* (Salt Lake City, Utah) 17 June 1947, p. 20. https://news.google.com/newspapers?nid=336&dat=19470617&id=F9s0AAAAIBAJ&sjid=kXcDAAAAIBAJ&pg=5662,5995342

Other journalists repeated much of this information in various publications from summer 1946 through 1947. See for example:

> Nazis Worked on Plane to Bomb U.S. *Hartford Courant* 15 July 1946, p. 1.
>
> Hitler Planned Supersonic Bomber to Hit New York. *Los Angeles Times* 15 July 1946, p. 2.
>
> List of Terror Weapons of Nazis Revealed by AAF. *Plattsburgh Press-Republican* (Plattsburgh, New York) 15 July 1946, p. 1.
>
> Nazi Scientists Worked on 136 Secret Weapons. *Times Record* (Troy, New York) 15 July 1946, p. 3.
>
> Transatlantic Roller Coaster Designed to Bomb U.S.A. *Popular Science* October 1947. https://neverwasmag.com/2018/09/wonder-weapons-of-the-third-reich/transatlantic-roller-coaster-designed-to-bomb-usa/

For more information on German and Allied threats and counter-threats to use nuclear, chemical, and biological weapons of mass destruction during the final years of the war, see pp. 2632–2651.]

Heinrich Himmler's chief adjutant Werner Grothmann on nuclear technology transfer to the United States [Krotzky 2002]. For a discussion of the background and reliability of this source, see pp. 3396–3397.

[S. 32] Die zweite Schwierigkeit bestand darin, dass die Zünder für die Waffe nicht so funktionierten, wie man sich das ursprünglich dachte. Die haben mit allem möglichen experimentiert. Es war, glaube ich, erst im Herbst 1944, dass jemand bei Diebner eine praktikable Lösung fand, die aber immer noch sehr aufwendig war. Und ungefähr zur selben Zeit hat dann bei uns jemand in Zusammenarbeit mit..., glaube ich, und noch ein Unternehmen war beteiligt, oder dort ein Experte, mit Infrarot-Zündern einigen Erfolg. Wir nannten, die Dinger damals Ultrarot-Zünder.

[p. 32] The second problem was that the fuse for the weapon was not working as originally intended. They experimented with all kinds of things. I believe it was first in the autumn of 1944 that someone with Diebner found a viable solution, which was still very elaborate. And about the same time, someone with us [SS] who worked in collaboration with ..., I believe, and another company was involved, or there was an expert, with infrared detonators some success. We called the things then infrared igniters.

[S. 45] Die Zünderentwicklung muß für alle Beteiligten eine richtige Nervensache gewesen sein. Ich bin ja kein Technik-Sachverständiger gewesen, aber im Laufe der Zeit bekam man doch etwas mit. Deshalb kann ich wenigstens sagen, dass Himmler wiederholt Fehlschläge gemeldet worden sind. Dabei hatte man ja wirklich die erste Garnitur von Experten damit beauftragt und außerdem ist an verschiedenen speziellen Zündern für die Atombombe gearbeitet worden. Wenn ich jetzt überlege, was mir dazu noch einfällt, ist es die Ultra-Rot-Sache. An Zündern die auf dieser Basis funktionieren sollten, ist nach meiner Erinnerung von ganz wenigen Leuten bei einer Optik-Firma in Zusammenarbeit mit einem Elektro-Unternehmen gearbeitet worden. Den Auftrag haben wir aber nicht vergeben, so weit ich weiß, der ist wahrscheinlich von Ohnesorge weitergegeben worden. Dieser Zünder soll noch kurz vor Kriegsende als Laborgerät für die ersten Funktionsprüfungen vorbereitet worden sein, mehr weiß ich dazu nicht. [...]

[p. 45] The ignition development must have been a real problem for everyone involved. I was not a technical expert, but in the course of time one learned something about it. That is why I can at least say that Himmler had repeatedly received reports of failed tests. Therefore the first set of experts had been commissioned, and out of that a number of special detonators for the atomic bomb had been worked on. If I think what else I can remember now, then it is the infrared thing. According to my memory, a very small number of people at an optics company, cooperating with an electrical company, worked on detonators that were supposed to function on this basis. We did not give the assignment, however, as far as I know, it was probably passed on by Ohnesorge. This detonator is said to have been prepared shortly before the end of the war as a laboratory device for the first functional tests, more I do not know. [...]

Dann gab es Vorschläge, das Atom-Sprengmaterial mit einem ganz unkonventionellen Zünder auszulösen. Der Vorschlag ist bei dem Treffen bei Innsbruck schon bekannt gewesen. Man muß sich das so vorstellen: es war die Rede davon, dass man für die Zündung sehr viel Energie benötigt, um das Material zu zünden. Da hatte ein Ingenieur von einer Technischen Hochschule in anderem Zusammenhang vorgeschlagen, so eine Art Radarstrahlen einzusetzen, weil man die wohl auf ganz kurze Entfernung sehr gut bündeln konnte und weil die Energie enthalten würden oder selbst Energie sind. Das weiß ich nicht genauer.[18] Jetzt gab es ja das Problem, dass wir im Frühjahre von den Physikern ganz klar hörten, die Entwicklung der Bombe ist auf gutem Weg, also das heißt erst mal, das Sprengmaterial wird man für die notwendigen Versuche erzeugen können und dann muß man sehen, wie viel davon für die richtige Bombe, erzeugt werden kann. Ohnesorge machte da mächtig Druck mit dem Argument, wenn wir die Bombe mit so viel Aufwand hinbekommen und dann fehlt der Zünder, ist der Krieg trotzdem verloren. Das war auch Himmlers Ansicht. Wir konnten den Krieg nicht mehr anders gewinnen als mit einer durchschlagenden Waffe. Deshalb sind ja solche Forschungsaufträge auch sofort weitergegeben worden und man hat auch mit einzelnen Firmen darüber gesprochen, dass die ihre besten Leute an diese Sache setzen sollten. Rausgekommen ist nach meiner Kenntnis auch bei dem Zünder nichts.

Then there were proposals to trigger the nuclear explosive material with a completely unconventional detonator. The proposal was already known at the meeting near Innsbruck. You have to imagine it like this: there was talk about the fact that you need a lot of energy to ignite the material. In another context, an engineer from a technical university had suggested to use some kind of radar beams, because they could be focused very well at a very short distance and because they would contain energy or are energy themselves. I do not know that more exactly.[18] Now there was the problem that in the early years we heard quite clearly from the physicists that the development of the bomb is well on the way, so that means first of all that the explosive material will be able to be produced for the necessary tests and then we must see how much of it can be produced for the real bomb. Ohnesorge put on a lot of pressure, arguing that if we could make the bomb with so much effort and then the fuse was missing, the war would still be lost. That was also Himmler's view. We could no longer win the war any other way than with a breakthrough weapon. That is why such research contracts were passed on immediately, and they also talked to individual companies about putting their best people to work on this. As far as I know, nothing came of that [particular] detonator.

---

[18] [Grothmann was not a scientist; his nonscientific description here seems to be referring to the use of a compact betatron as a neutron initiator. Grothmann would not be expected to understand the physics details of betatrons, but they use an electron beam and a magnetic field, as does a cavity magnetron for radar, with which Grothmann was probably much more familiar. Thus Grothmann was describing "a completely unconventional" device that used an electron beam and magnetic field to "focus" a "beam" over a "very short distance" "to trigger the nuclear explosive material." A betatron mounted on the outside of a fission implosion bomb could fire a high-energy electron beam toward the center of the bomb at the moment of implosion. The energy of the electrons would be converted to gamma rays via the bremsstrahlung process. Gamma rays absorbed by some ^{235}U or ^{239}Pu nuclei could release neutrons, which could initiate a fission chain reaction in the rest of the ^{235}U or ^{239}Pu fuel. The United States successfully demonstrated a betatron neutron initiator in a fission bomb on 1 June 1952 in the George test of Operation Tumbler-Snapper [https://nuclearweaponarchive.org/Usa/Tests/Tumblers.html].

In March 1945, Ivan Ilyichev reported that this method was one of the neutron initiators used in German atomic bombs (p. 4487: "Bomb ignition": "Ahead of this, before the explosion, the uranium sphere is irradiated with gamma-rays, the energy of which does not exceed 6 million electron volts, which many times increases its explosive qualities."). Compact, light-weight 6- and 7-MeV betatrons ideally suited for this particular application were manufactured during the war by Siemens-Reiniger Werke in Erlangen (pp. 3088–3089, 3957–3970).]

Dann gab es einen Vorschlag, der kam aus Österreich und war sehr gut begründet. Der schien ganz pfiffig. Mir war er nur als Netzzünder bekannt geworden. Im Versuch funktionierte er aber nur wie ich hörte, wenn die Position bestimmter Zünderteile ganz genau, also wirklich millimetergenau eingehalten werden konnte. Gab es eine winzige Lageveränderung war alles umsonst. Den konnte man natürlich so nicht einsetzen. Diebner hat übrigens selbst Zünder-Experimente angeregt, aber erst im Herbst 44 bekam man ein einigermaßen funktionierendes Ding hin.

[S. 34] Für das hier verbürge ich mich aber: Aus unseren Forschungs- und Entwicklungslabors in Thüringen sind Teile des Materials verbracht worden, aber nicht alles. Warum das so geschah, weiß ich nicht. Zumindest das wenige radioaktive Material für die erste Bombe und einen Teil des Zündmechanismus sollen dann die Amerikaner mitgenommen haben. Die von den Amerikanern erbeuteten Prototyp-Teile für unsere erste richtige Atombombe sind sofort von ihnen zum “Adlerhorst” gebracht worden. Ab da weiß ich nichts mehr dazu. Es gibt noch vielleicht, noch jemanden, der das bestätigen kann.

[S. 40] Die Sieger haben die Beute mitgenommen und spater der Öffentlichkeit ihre glänzende Rüstung vorgeführt. Bei Flugzeugen war das so, bei der U-Boot-Technik, in der Chemie und auch so manchen unserer tüchtigen Atomphysiker haben sie dann für sich arbeiten lassen, genauso wie die Raketenleute.

Then there was a proposal from Austria, which was justified very well. It seemed quite clever. I only knew it was called network ignition. In the experiment, however, it only worked as I heard, if the position of certain detonators was very exact, that is, precise to the millimeter. If there was a tiny change of location, all was in vain. Of course you could not use it that way. By the way, Diebner himself suggested detonator experiments, but it was not until autumn 44 that a well-functioning thing was discovered.

[p. 34] For this, however, I can vouch myself: Parts of the material had been removed from our research and development laboratories in Thuringia, but not everything. Why this happened, I do not know. The Americans are supposed to have taken at least the small amount of radioactive material for the first bomb and a part of the ignition mechanism. The prototype parts for our first real atomic bomb that were captured by the Americans were immediately taken to the “Eagle’s Nest.” I do not know any more about it, there may be someone who can confirm it.

[p. 40] The winners took the booty and later presented their shining armaments to the public. That was true for airplanes, with submarine technology, in chemistry, and with many of our capable nuclear physicists, who worked for them [Allied countries], just like the rocket people.

[In the first four quoted paragraphs, Grothmann told how German and Austrian engineers invented and tested several different detonation timing systems to allow the spherical implosion bomb (which he described elsewhere) to create a detonation with "millimeter-exact" accuracy across all of the ignition points around the bomb. As examples, he recounted a sophisticated optical method using infrared signaling to the detonators, and another system called "network ignition," likely an electrical network of exploding bridgewire detonators. Erich Schumann appears to have referred to exploding bridgewire detonators in his description of German implosion bombs (p. 4241).

Adlerhorst or Eagle's Nest was located near Bad Nauheim, and should not be confused with the better known Eagle's Nest or Kehlsteinhaus near Berchtesgaden. Adlerhorst was captured by the U.S. Army on 30 March 1945, and subsequently was used by the Allies as "Operation Dustbin" to imprison and interrogate high-value German intelligence targets, including Albert Speer, Wernher von Braun, and many others.

If the United States captured German atomic bomb components and immediately took them to Adlerhorst, those components could have been captured no earlier than April 1945. Since the United States could have taken the components to many other sites that were equally or more secure, Grothmann's statement that they were taken to Adlerhorst suggests that those components were shown to high-value German detainees so that they could not deny the existence of the German nuclear program. Furthermore, that would suggest that the United States had not captured a satisfactory amount of information about the nuclear program, and was desperate to learn more from the detainees. Is it possible to locate and declassify any U.S. records on what German atomic bomb components were found, or what the United States learned from German detainees?

If precisely timed implosion detonators or other sophisticated nuclear weapons components were captured in Europe in April–May 1945 or on the U-234 or other surrendered German submarines, those components may have been used to make final improvements to the U.S. fission bombs before they were detonated in New Mexico and Japan (p. 4880).

See p. 4992 for a very incomplete list of some German and Austrian nuclear-related scientists and engineers who temporarily visited or permanently moved to the United States or United Kingdom after the war, just as Grothmann said.]

From Office of Strategic Services Shepardson to Amzon. 10 September 1945. [NARA RG 226, Entry A1-134, Box 219, Folder 1371: OUT AZUSA Nov. '43 Sept. '45]

Any information gained concerning German scientists on AZUSA send only to Lt. Col. Horace K. Calvert care U. S. Embassy, London, and do not pass to G-2 USFET. This also applies other fields. Send copies Washington.

H. W. Dix to Francis J. Smith. 13 September 1945. Office of Strategic Services memo AA-217. [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-3 GERMANY: US Wartime Positive Int. (Nov. 44–June 45)]

Cable from our German office reads in accordance with the two following paragraphs:

> 1. Referring further our recent exchange cables RE handling Azusa material, General Sibert who has just returned here from Washington has informed us (A) that when in Washington he was given full information concerning this subject and all matters pertaining to it including U.S. policy (B) that he was designated as coordinator all such information in this theater and (C) that we are to disseminate all our information this subject to him and no one else in theater.
>
> 2. As OSS Germany is under direction command USFET, we consider General Sibert's instructions this subject as an order which we cannot ignore. If you disapprove we suggest as only solution that you approach War Department Washington with request that Sibert's instructions be altered.

This is different than our instructions to our office in Germany. The instructions we forwarded were from your office.

Please advise which way you desire our office in Germany to handle

> (a) the information about the search for German scientists
>
> (b) all information on this topic.

From Office of Strategic Services Shepardson to Berlin via Amzon. 14 September 1945. [NARA RG 226, Entry A1-134, Box 219, Folder 1371: OUT AZUSA Nov. '43 Sept. '45]

WASH 6437. AZUSA. To 110 Berlin from 154 and Dix. Information: Wisner Amzon.

RE BERL 1059 (IN 23766), please see WASH 3567 to Wisner. Our work on this subject is to correlate and cooperate with specially appointed general who has charge of the whole AZUSA situation and has overall responsibility.

In order that he may make decisions we pass our information to him, and thereby proceed as he may direct.

On present sub feature of AZUSA about assisting locating German scientists, special general asked to have the information sent only to Calvert, London Embassy, or to Washington.

RE your AMZO 4437 (IN 240370); our WASH 1167 and WASH 3567 were special general's instructions until he could talk with Sibert here. This now done and all AZUSA information obtained by OSS in ETO and applicable in ETO situations now to be coordinated only between you or Wisner Sibert and Calvert and advising OSS Washington of resulting decisions or information. This insures desired maximum security with fewest number persons involved. Copies of any reports to be sent OSS Washington without delay and showing action taken.

This subject so tight at this time we are playing very close with special general.

Phrase "other fields" from your BERL #2417 interpreted here as within scope AZUSA matters only and not applicable to all technical matters. WASH 3567 repeated the words "other fields" thereby trying to eliminate misunderstanding. This answers AMZO 3917.

[See document photo on p. 5048. Do these OSS cables show that the U.S. started to really appreciate the extent of the wartime German nuclear program by September 1945, and took steps to limit that knowledge to the "fewest number persons"? Is that why Zinsser's report of a German atomic bomb test was upgraded from Secret to Top Secret in early October 1945 (p. 4422)? Who was the "special general"—Leslie Groves or someone else?]

Captain Hugh T. Cunningham, Strategic Services Unit, to Brigadier General Edwin L. Sibert, U.S. Army, 6 May 1946. Subject: German Atomic Research [NARA RG 226, Entry A1-215, Box 6, Folder WN26150–26164]

1. One of our reliable sources is in contact with a certain Chef-Chemiker Sallie, at present employed in a chemical industry in Constance, who claims to be able to give detailed information on German atomic research as of February 1945. Sallie was in Berlin when the Russians blew up the Treasury Building in which the documents on German atomic research were stored, and claims to know exactly what documents thereby fell into the hands of the Russians.

2. If this man is of interest for further exploitation we can instruct our source accordingly.

WAR DEPARTMENT
WAR DEPARTMENT GENERAL STAFF
MILITARY INTELLIGENCE DIVISION G-2
WASHINGTON

25 October 1945

SUBJECT: Collection of Intelligence on Nuclear Physics.

To: The Assistant Chief of Staff, G-2, U. S. Forces, European Theater, APO 757, c/o Postmaster, New York, New York

1. The questions raised on your recent visit regarding the responsibility of G-2, USFET, to gather information on nuclear physics and what agencies are authorized to send field intelligence investigators on nuclear physics into the theater are answered as follows:

a. The responsibility for the gathering of intelligence in the European Theater (Chart, War Department Administrative Boundaries, Appendix B, 25 April 1945) is considered the duty of G-2, USFET. The Chief of the Manhattan Engineer District desires, however, that all information on nuclear physics obtained byyour office be channelized to the representatives of his office who are designated as advisory and liaison officers to USFET Headquarters. The dissemination of information on atomic energy within USFET Headquarters must be restricted to as few persons as is practicable for its proper handling.

b. Since the dissolution of ALSOS, there is no agency that is authorized to send investigators into the field on nuclear physics, except those persons specifically designated by the office of the Chief of the Manhattan Engineer District. This policy is necessary because of certain directives of the Secretary of War and of certain international commitments of the United States.

2. On matters concerning this subject it is requested that, where appropriate, coordination be effected between your office and the Military Attache of the respective countries within the European Theater. In this connection the essential elements of information for the countries within the European Theater will be sent to G-2, USFET, and the Military Attache to the country involved.

3. Instructions regarding the responsibility of G-2, USFET, in the general field of scientific military intelligence collection, other than nuclear physics, are being covered in a separate letter.

4. A copy of this letter is being furnished all Military Attaches in the European Theater for their information and guidance.

THE MAKING OF AN EXACT COPY OF THIS MESSAGE IS FORBIDDEN

NARA RG 77, Entry UD-22A, Box 160, Folder Apr 45—Dec. '45

Figure D.1001: After the war, OSS agent Moe Berg was sent on a mission by "Eugene" (probably a code name for a high-ranking person in the OSS or Manhattan Engineer District, or possibly Eugene Wigner?) to determine which German-speaking nuclear scientists had been recruited or captured by the Soviet Union ("Boris"). The "material from Hildesheim" included German uranium from Stassfurt [NARA RG 77, Entry UD-22A, Box 160, Folder Apr 45–Dec. '45].

Moe Berg. 1952. Handwritten notes. [Princeton University Library, Special Collections, Moe Berg Papers (C1413), Box 20, Folder 3—Loose Notes: Central Intelligence Agency.]

[See excerpts on pp. 5052–5063.

Moe Berg's 1952 notes reveal how extensively the postwar Soviet nuclear weapons program depended on scientists, companies, and resources from the wartime German nuclear weapons program.

Berg's notes appear to draw heavily upon a 1951 version of a CIA document, National Intelligence Survey (NIS) 26 (U.S.S.R.), Chapter VII, Section 73 (Atomic Energy). I have not been able to find that version, but a later 1955 version is available at:

https://www.cia.gov/readingroom/document/0000198124

https://www.cia.gov/readingroom/docs/DOC_0000198124.pdf

However, that 1955 version omits most of the information in pp. 5052–5063, probably because it was "old news" by then.

See pp. 3468–3471 for excerpts from the 1955 version that discuss postwar Soviet use of uranium sources from the wartime German nuclear weapons program.

If Moe Berg and his CIA colleagues knew this much about the highly secretive Soviet nuclear weapons program during the early Cold War, how much did Berg and his OSS colleagues know about the highly secretive German nuclear weapons program during World War II?

Among many other relevant details in Berg's notes, notice that:

Leftover wartime factories in Neustadt an der Orla, East Germany, were perfectly set up to make high-quality nickel membrane filters for gaseous diffusion uranium enrichment plants (pp. 5052, 5055–5057). Manufacturing the filters was so difficult that even years after the war, Soviet plants could not make comparable items. What exactly did these German factories do during the war? Did wartime Germany build gaseous diffusion uranium enrichment plants (Section D.4.4)?

Ludwig Bewilogua (p. 5059) was extremely important for the postwar Soviet fission reactor program. What exactly did he do during the war? Note that another postwar U.S. intelligence report stated that Bewilogua was a "wartime expert on uranium piles" (p. 3991).

Wartime plants at I.G. Farben's Bitterfeld site were able to produce enough calcium for most of the huge postwar Soviet nuclear weapons program (pp. 5052, 5054). Calcium is used for key steps in purifying uranium metal (pp. 4132–4136). How much nuclear-weapons-related work did those plants do during the war? During the war, the Bitterfeld facility also produced heavy water (p. 4050), graphite (p. 4110), aluminum (p. 4128), and perhaps other potentially nuclear-related materials.

Czech manufacturers such as Skoda and Brünner were making significant contributions to the postwar Soviet nuclear weapons program (p. 5053), just as they apparently had for the wartime German nuclear weapons program (e.g., p. 4914).

Several Swiss factories were manufacturing and selling nuclear-related components to the postwar Soviet nuclear weapons program (p. 5053). Did they do the same for the wartime German program?]

in research on barrier material justified
this development. The U.S. tried out three
methods for sep. of the fissionable isotope
of U, namely: thermal diffusion
electromagnetic separation
gaseous diffusion

* thermal diffusion method: produced some
enriched feed material for the electromagnetic
separation plant * discontinued & its
plant dismantled.

* electromagnetic separation method: was
used to prepare the original weapon grade
U-235 → this plant since diverted to other uses

* at present: only the gaseous diffusion
method is used in the U.S. for the prod. of U-235

* in gaseous diffusion process, the gas =
uranium hexafluoride diffuses through a
porous barrier with an enrichment of the light
isotope on the low-pressure side. The enrichment
per stage is very slight, & approximately
4,000 stages are req'd to get U-235 of weapon
quality — requires many millions of sq. ft

of barrier, the efficiency of which determines
the production* → the K-25 plant @ Oak Ridge
is the largest + most complex single
industrial plant in the world, but the prod.
of a suitable barrier in suff. quantity proved
to be the most important & most difficult*
problem to solve in bldg such a plant.
→ 1947 a successful barrier was being
tested @ the KURNAKOV Inst. of Gen. & Inorg.
Chem. under the Moscow Acad. of Sc. – by
mid-1948, USSR had started prod. of the
fine nickel wire mesh needed as backing
for their barrier. This wire mesh is extremely
difficult to produce, & only a few firms
in the Soviet zone of Germany & apparently
none in USSR, could make this product.
The fine nickel wire is drawn thru diamond
dies & woven in special looms – @ first, the
thread count was 250 per inch – later reduced
to 210 per inch when it was found impossible
to get a sufficient quantity of the fine mesh.

Princeton University Library, Special Collections, Moe Berg Papers (C1413), Box 20, Folder 3–Loose Notes: Central Intelligence Agency

Figure D.1006: Moe Berg's 1952 notes reveal how extensively the postwar Soviet nuclear weapons program depended on scientists, companies, and resources from the wartime German nuclear weapons program [Princeton University Library, Special Collections, Moe Berg Papers (C1413), Box 20, Folder 3—Loose Notes: Central Intelligence Agency].

agusa

A HILTON HOTEL WASHINGTON · D.C.

- in 1949, prod: of fine wire mesh was behind
the quota for that year — but in 1950 an in-
creased quota was substantially exceeded:
* getting the steel combs for the looms, &
the thousands of diamond dies needed for
drawing the wire appeared: chief difficulty
* Samples of the mesh made for the SOVIETS
have been secured & tested & indicate: USSR
may have a barrier equal in performance
to that originally used by U.S. — from prod.
rate of the wire mesh, estimated: beg's
mid-1951, USSR may have enuf barrier
to produce weapon-grade U-235 in
substantial quantities * @ first, the rate
of prod. will be only a small fraction of
the K-25 plant, but a large increase in
prod. facilities shld be reached / end of
1952
* in the U-235 program, less reason to believe:
USSR are attempting to duplicate U.S. practice
than in the pile program & possibly the bomb
design * much more evid. of extensive

H. S. Lowenhaupt

(Joachimsthal Mines)

1. Cable No. 70986, 6 September 1946, from Major P. O. Langguth, states with a very high evaluation the following:

a. General Svoboda and Bocek, Czech Minister of National Defense and Chief of Staff, visited the mines on 13 August 1946 upon the termination of a three-day conference in Prague. The conference was attended by over two hundred "Reds." Soviet engineers have reported that deposits are sufficient for Russian demands. Plans have been drafted to employ 4,500 miners from Pribram. Russia has promised to supply increased foodstuffs and luxuries. Russian mineralogists (living at Hotels Pupp and Imperial in Karlsbad) claim discoveries of new and richer deposits in the Joachimsthal area. These will be exploited only by the Russians. A request by the Czechs to have the concentration plant in their territory was denied by the Russians. As in the past all ore will go to Dresden (presumably for either transmittal or concentration).

To McNarney from Joint Intelligence Committee

Under authority in WAR 92817 the Joint Intelligence Commitee hereby modifies list therein to include the following:

> Applied and theoretical nuclear physics, including design and operation of devices for producing highly energetic particles, and isotope separation.
>
> Control of guided missiles and homing devices (air and water).
>
> All asdic (sonar) devices.
>
> All proximity fuzes.
>
> Extremely potent chemicals producing physiological effects.
>
> Cold weather operations including guided missile launching.

[These lists come from people who would definitely have known what they were talking about. They were classified Top Secret and sent directly from the U.S. Joint Chiefs of Staff to General Joseph T. McNarney, who at the time was both the military governor of the U.S.-occupied zone of Germany and also the commander in chief of the U.S. Forces of Occupation in Europe. Others who received the lists (and probably helped to create them) included General Leslie Groves, who was still in charge of all U.S. nuclear work and intelligence on foreign nuclear work. These lists were written over a year after the end of the war in Europe, after the U.S. had had time to investigate wartime German R&D in detail. Coming from that authoritative position, these lists appear to show that:

- All of these German programs (including nuclear and biological warfare) actually existed; otherwise the Joint Chiefs would not have included them in such a carefully chosen high-priority list, putting them on the same level as well documented programs such as sarin and soman.
- German work in these areas was so advanced that the United States was determined both to obtain that German work for itself and also to try to prevent other countries (other than the United Kingdom) from obtaining it.

What was the “method of causing temporary blindness by ultraviolet rays”?]

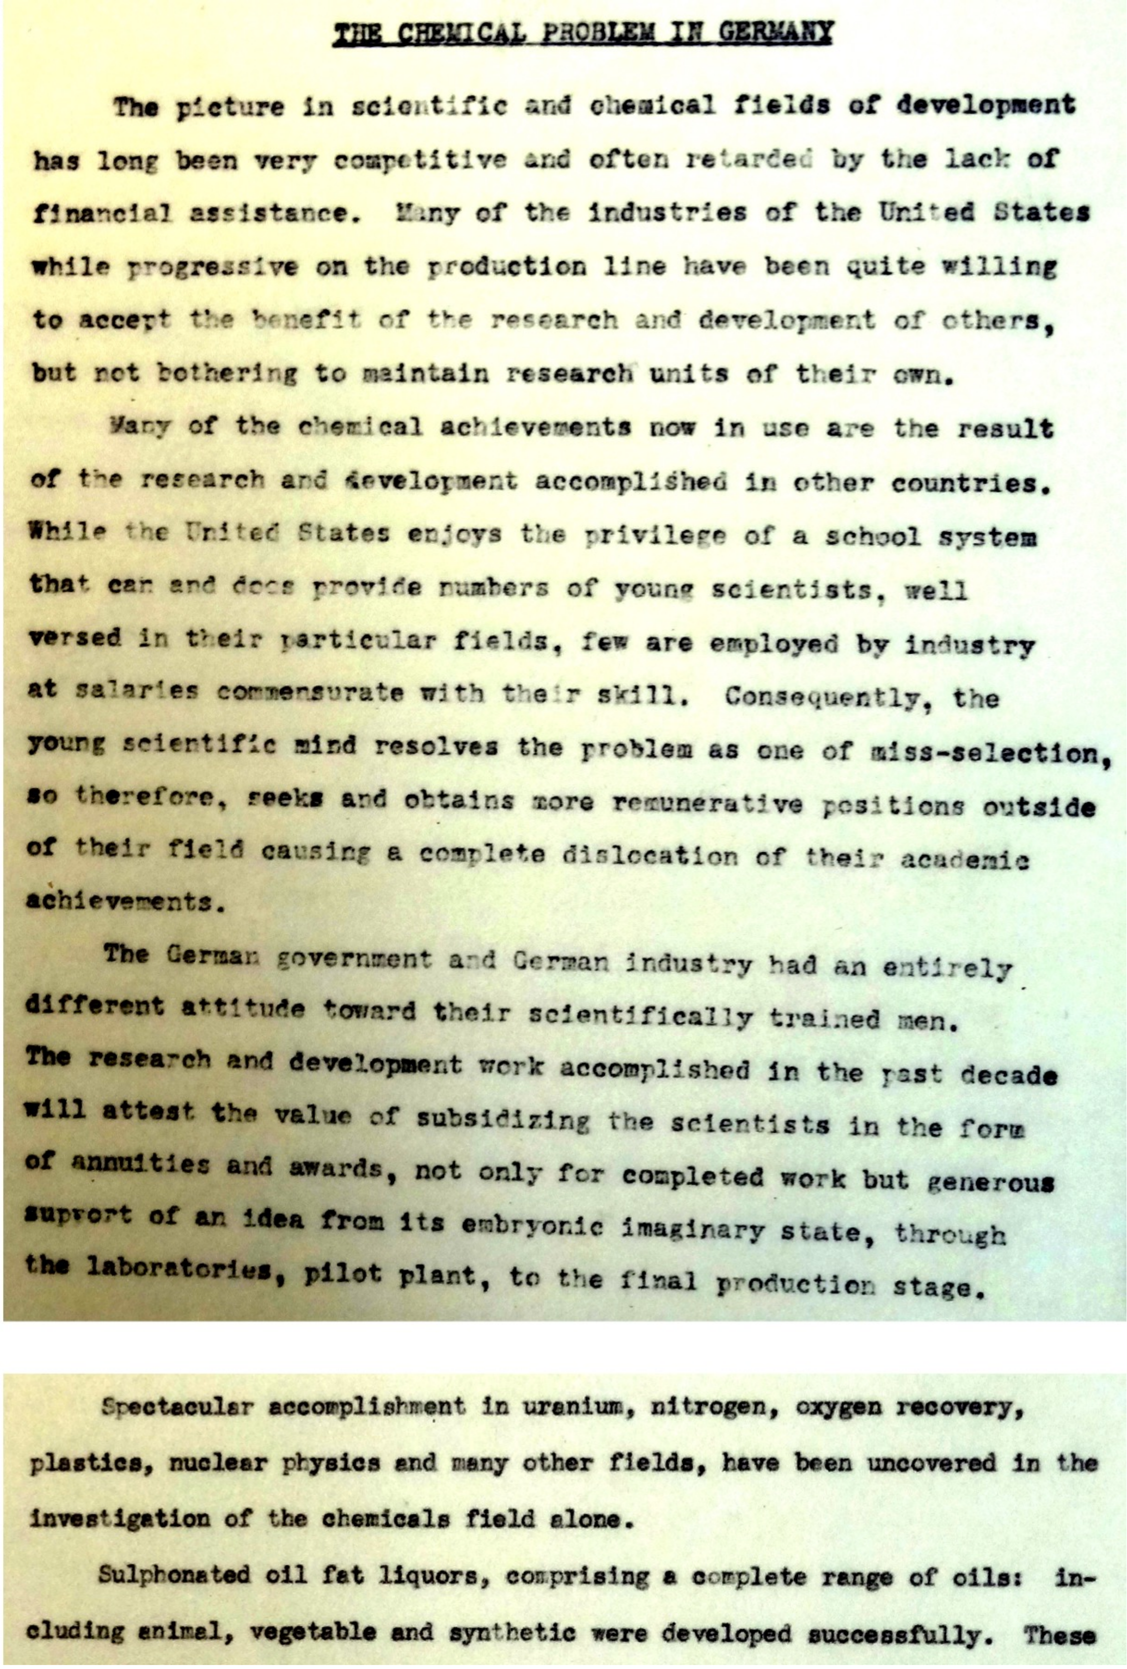
Press Releases, The Chemical Problem in Germany



THE CHEMICAL PROBLEM IN GERMANY

The picture in scientific and chemical fields of development has long been very competitive and often retarded by the lack of financial assistance. Many of the industries of the United States while progressive on the production line have been quite willing to accept the benefit of the research and development of others, but not bothering to maintain research units of their own.

Many of the chemical achievements now in use are the result of the research and development accomplished in other countries. While the United States enjoys the privilege of a school system that can and does provide numbers of young scientists, well versed in their particular fields, few are employed by industry at salaries commensurate with their skill. Consequently, the young scientific mind resolves the problem as one of miss-selection, so therefore, seeks and obtains more remunerative positions outside of their field causing a complete dislocation of their academic achievements.

The German government and German industry had an entirely different attitude toward their scientifically trained men. The research and development work accomplished in the past decade will attest the value of subsidizing the scientists in the form of annuities and awards, not only for completed work but generous support of an idea from its embryonic imaginary state, through the laboratories, pilot plant, to the final production stage.

Spectacular accomplishment in uranium, nitrogen, oxygen recovery, plastics, nuclear physics and many other fields, have been uncovered in the investigation of the chemicals field alone.

Sulphonated oil fat liquors, comprising a complete range of oils: including animal, vegetable and synthetic were developed successfully. These

Joint Intelligence Staff,
The Joint Chiefs of Staff,
Washington 25, D.C.

Dear Mr. Webb:

Thank you for bringing to my attention the letter from Mr. C. W. Hansell and also the information concerning Dr. Walter Bothe and the cyclotron in Heidelberg.

I have taken this matter up with the proper authorities and you may assure Mr. Hansell that the appropriate investigations have been conducted in Germany by competent investigators in the field of nuclear physics.

You may further advise Mr. Hansell that reports of this nature are not being declassified at the present time. However, every effort is being made to make public as rapidly as the military situation permits all scientific information that may be of interest to scientists.

Very truly yours,

V. Bush,
Director.

Col Shuler

WAR DEPARTMENT
P. O. Box 2610
WASHINGTON, D. C.

REFER TO FILE No. ______

Gen.-Sum Rpts-TA

10 September 1946

SUBJECT: Status of Nuclear Energy Situation in Germany.

TO: Colonel W. R. Shuler

A. Introduction

1. The following is a brief summary of the present situation in Germany and adjacent territories of informative and intelligence interest on the subject of nuclear energy as developed by the undersigned officer during his tour of duty (27 July to 2 September 1946) at USFET Frankfurt a/M.

2. The mission of the undersigned, as discussed with various members of the MED, was briefly as follows:

a. To evaluate and take necessary action on intelligence matters relating to nuclear energy at USFET Hqs., in accordance with the wishes of Brig. Gen. Edwin L. Sibert, AC of S G-2.

b. To check on the location and activities in the American Zone of the better German scientists qualified in nuclear physics.

c. To inventory specialized laboratory equipment usable in nuclear research.

d. To investigate and uncover any additional supplies of uranium materials.

32.60

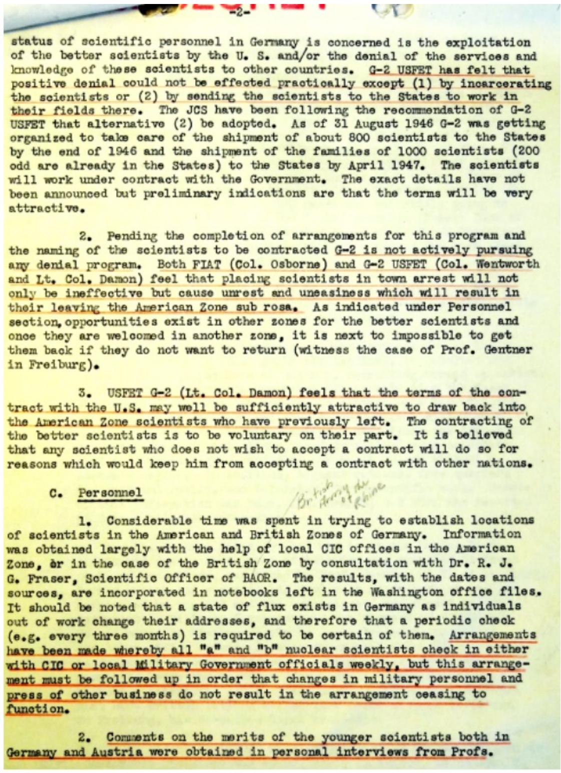
3. While on this mission, the undersigned worked in close cooperation with Lt. Col. J. C. Damon, Chief, Technical Intelligence Section, Operations Branch, G-2, and with Col. R. D. Wentworth, Chief, Operations Branch, G-2, who are cognizant of the information contained in this report.

4. The information summarized herein was developed by study of intelligence reports emanating from various intelligence agencies in the theater, by interviews with German scientists (Memos on which conversations have been submitted to the Washington Office) and visits to and discussions with field officers of the Counter Intelligence Corps, Military Government, FIAT (Field Intelligence Agency Technical) G-2 USF Austria, and SSU (Strategic Services Unit).

B. Denial Program

1. The most important problem facing USFET as far as the

TOP SECRET



-2-

status of scientific personnel in Germany is concerned is the exploitation of the better scientists by the U. S. and/or the denial of the services and knowledge of these scientists to other countries. G-2 USFET has felt that positive denial could not be effected practically except (1) by incarcerating the scientists or (2) by sending the scientists to the States to work in their fields there. The JCS have been following the recommendation of G-2 USFET that alternative (2) be adopted. As of 31 August 1946 G-2 was getting organized to take care of the shipment of about 800 scientists to the States by the end of 1946 and the shipment of the families of 1000 scientists (200 odd are already in the States) to the States by April 1947. The scientists will work under contract with the Government. The exact details have not been announced but preliminary indications are that the terms will be very attractive.

2. Pending the completion of arrangements for this program and the naming of the scientists to be contracted G-2 is not actively pursuing any denial program. Both FIAT (Col. Osborne) and G-2 USFET (Col. Wentworth and Lt. Col. Damon) feel that placing scientists in town arrest will not only be ineffective but cause unrest and uneasiness which will result in their leaving the American Zone sub rosa. As indicated under Personnel section, opportunities exist in other zones for the better scientists and once they are welcomed in another zone, it is next to impossible to get them back if they do not want to return (witness the case of Prof. Gentner in Freiburg).

3. USFET G-2 (Lt. Col. Damon) feels that the terms of the contract with the U.S. may well be sufficiently attractive to draw back into the American Zone scientists who have previously left. The contracting of the better scientists is to be voluntary on their part. It is believed that any scientist who does not wish to accept a contract will do so for reasons which would keep him from accepting a contract with other nations.

C. Personnel

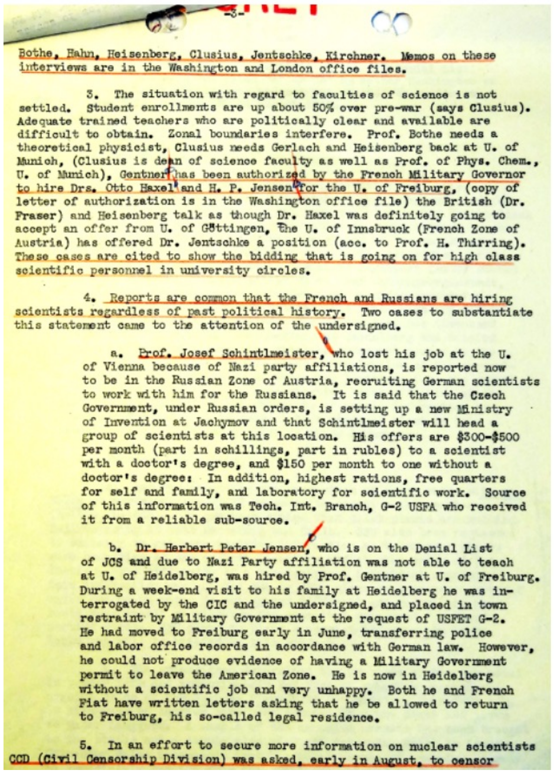
British Army of the Rhine

1. Considerable time was spent in trying to establish locations of scientists in the American and British Zones of Germany. Information was obtained largely with the help of local CIC offices in the American Zone, or in the case of the British Zone by consultation with Dr. R. J. G. Fraser, Scientific Officer of BAOR. The results, with the dates and sources, are incorporated in notebooks left in the Washington office files. It should be noted that a state of flux exists in Germany as individuals out of work change their addresses, and therefore that a periodic check (e.g. every three months) is required to be certain of them. Arrangements have been made whereby all "a" and "b" nuclear scientists check in either with CIC or local Military Government officials weekly, but this arrangement must be followed up in order that changes in military personnel and press of other business do not result in the arrangement ceasing to function.

2. Comments on the merits of the younger scientists both in Germany and Austria were obtained in personal interviews from Profs.

DECLASSIFIED
Authority 917017

NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)



-3-

Bothe, Hahn, Heisenberg, Clusius, Jentschke, Kirchner. Memos on these interviews are in the Washington and London office files.

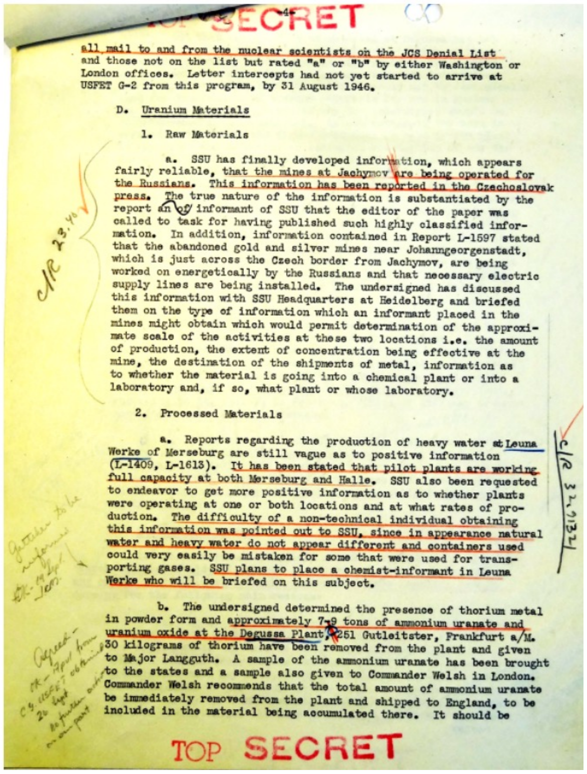
3. The situation with regard to faculties of science is not settled. Student enrollments are up about 50% over pre-war (says Clusius). Adequate trained teachers who are politically clear and available are difficult to obtain. Zonal boundaries interfere. Prof. Bothe needs a theoretical physicist, Clusius needs Gerlach and Heisenberg back at U. of Munich, (Clusius is dean of science faculty as well as Prof. of Phys. Chem., U. of Munich), Gentner has been authorized by the French Military Governor to hire Drs. Otto Haxel and H. P. Jensen for the U. of Freiburg, (copy of letter of authorization is in the Washington office file) the British (Dr. Fraser) and Heisenberg talk as though Dr. Haxel was definitely going to accept an offer from U. of Göttingen, the U. of Innsbruck (French Zone of Austria) has offered Dr. Jentschke a position (acc. to Prof. H. Thirring). These cases are cited to show the bidding that is going on for high class scientific personnel in university circles.

4. Reports are common that the French and Russians are hiring scientists regardless of past political history. Two cases to substantiate this statement came to the attention of the undersigned.

a. Prof. Josef Schintlmeister, who lost his job at the U. of Vienna because of Nazi party affiliations, is reported now to be in the Russian Zone of Austria, recruiting German scientists to work with him for the Russians. It is said that the Czech Government, under Russian orders, is setting up a new Ministry of Invention at Jachymov and that Schintlmeister will head a group of scientists at this location. His offers are \$300-\$500 per month (part in schillings, part in rubles) to a scientist with a doctor's degree, and \$150 per month to one without a doctor's degree: In addition, highest rations, free quarters for self and family, and laboratory for scientific work. Source of this information was Tech. Int. Branch, G-2 USFA who received it from a reliable sub-source.

b. Dr. Herbert Peter Jensen, who is on the Denial List of JCS and due to Nazi Party affiliation was not able to teach at U. of Heidelberg, was hired by Prof. Gentner at U. of Freiburg. During a week-end visit to his family at Heidelberg he was interrogated by the CIC and the undersigned, and placed in town restraint by Military Government at the request of USFET G-2. He had moved to Freiburg early in June, transferring police and labor office records in accordance with German law. However, he could not produce evidence of having a Military Government permit to leave the American Zone. He is now in Heidelberg without a scientific job and very unhappy. Both he and French Fiat have written letters asking that he be allowed to return to Freiburg, his so-called legal residence.

5. In an effort to secure more information on nuclear scientists CCD (Civil Censorship Division) was asked, early in August, to censor



-4-

SECRET

all mail to and from the nuclear scientists on the JCS Denial List and those not on the list but rated "a" or "b" by either Washington or London offices. Letter intercepts had not yet started to arrive at USFET G-2 from this program, by 31 August 1946.

D. Uranium Materials

1. Raw Materials

CIR 23.40

a. SSU has finally developed information, which appears fairly reliable, that the mines at Jachymov are being operated for the Russians. This information has been reported in the Czechoslovak press. The true nature of the information is substantiated by the report of an informant of SSU that the editor of the paper was called to task for having published such highly classified information. In addition, information contained in Report L-1597 stated that the abandoned gold and silver mines near Johanngeorgenstadt, which is just across the Czech border from Jachymov, are being worked on energetically by the Russians and that necessary electric supply lines are being installed. The undersigned has discussed this information with SSU Headquarters at Heidelberg and briefed them on the type of information which an informant placed in the mines might obtain which would permit determination of the approximate scale of the activities at these two locations i.e. the amount of production, the extent of concentration being effective at the mine, the destination of the shipments of metal, information as to whether the material is going into a chemical plant or into a laboratory and, if so, what plant or whose laboratory.

2. Processed Materials

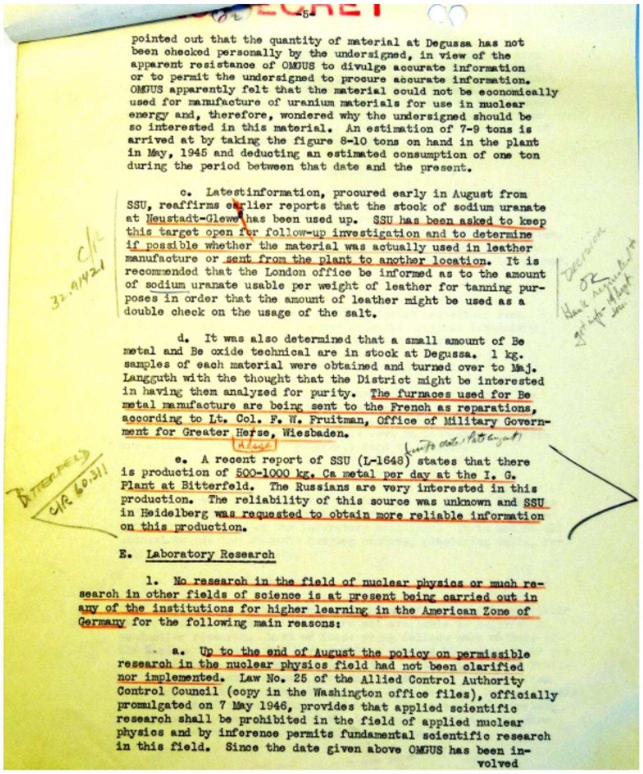
a. Reports regarding the production of heavy water at Leuna Werke of Merseburg are still vague as to positive information (L-1409, L-1613). It has been stated that pilot plants are working full capacity at both Merseburg and Halle. SSU also been requested to endeavor to get more positive information as to whether plants were operating at one or both locations and at what rates of production. The difficulty of a non-technical individual obtaining this information was pointed out to SSU, since in appearance natural water and heavy water do not appear different and containers used could very easily be mistaken for some that were used for transporting gases. SSU plans to place a chemist-informant in Leuna Werke who will be briefed on this subject.

C/R 32.9132

b. The undersigned determined the presence of thorium metal in powder form and approximately 7-9 tons of ammonium uranate and uranium oxide at the Degussa Plant, 251 Gutleitster, Frankfurt a/M. 30 kilograms of thorium have been removed from the plant and given to Major Langguth. A sample of the ammonium uranate has been brought to the states and a sample also given to Commander Welsh in London. Commander Welsh recommends that the total amount of ammonium uranate be immediately removed from the plant and shipped to England, to be included in the material being accumulated there. It should be

TOP SECRET

Figure D.1018: Canfield Hadlock to W. R. Shuler. 10 September 1946. Subject: Status of Nuclear Energy Situation in Germany [NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)].



-5-

pointed out that the quantity of material at Degussa has not been checked personally by the undersigned, in view of the apparent resistance of OMGUS to divulge accurate information or to permit the undersigned to procure accurate information. OMGUS apparently felt that the material could not be economically used for manufacture of uranium materials for use in nuclear energy and, therefore, wondered why the undersigned should be so interested in this material. An estimation of 7-9 tons is arrived at by taking the figure 8-10 tons on hand in the plant in May, 1945 and deducting an estimated consumption of one ton during the period between that date and the present.

c. Latestinformation, procured early in August from SSU, reaffirms earlier reports that the stock of sodium uranate at Neustadt-Glewe has been used up. SSU has been asked to keep this target open for follow-up investigation and to determine if possible whether the material was actually used in leather manufacture or sent from the plant to another location. It is recommended that the London office be informed as to the amount of sodium uranate usable per weight of leather for tanning purposes in order that the amount of leather might be used as a double check on the usage of the salt.

C/R 32.91421

Decision OK Hank requested to get info – 14 Sept

d. It was also determined that a small amount of Be metal and Be oxide technical are in stock at Degussa. 1 kg. samples of each material were obtained and turned over to Maj. Langguth with the thought that the District might be interested in having them analyzed for purity. The furnaces used for Be metal manufacture are being sent to the French as reparations, according to Lt. Col. F. W. Fruitman, Office of Military Government for Greater Herse, Wiesbaden.

Hesse

Info to date / Part August

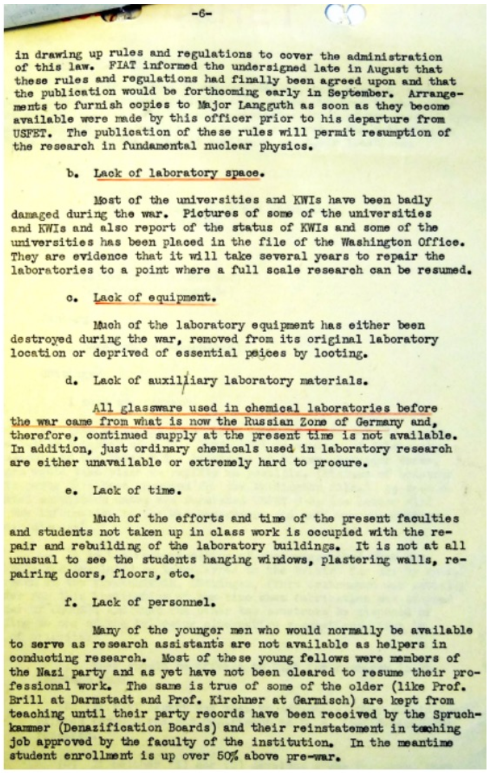
e. A recent report of SSU (L-1648) states that there is production of 500-1000 kg. Ca metal per day at the I. G. Plant at Bitterfeld. The Russians are very interested in this production. The reliability of this source was unknown and SSU in Heidelberg was requested to obtain more reliable information on this production.

Bitterfeld C/R 60.311

E. Laboratory Research

1. No research in the field of nuclear physics or much research in other fields of science is at present being carried out in any of the institutions for higher learning in the American Zone of Germany for the following main reasons:

a. Up to the end of August the policy on permissible research in the nuclear physics field had not been clarified nor implemented. Law No. 25 of the Allied Control Authority Control Council (copy in the Washington office files), officially promulgated on 7 May 1946, provides that applied scientific research shall be prohibited in the field of applied nuclear physics and by inference permits fundamental scientific research in this field. Since the date given above OMGUS has been involved



-6-

in drawing up rules and regulations to cover the administration of this law. FIAT informed the undersigned late in August that these rules and regulations had finally been agreed upon and that the publication would be forthcoming early in September. Arrangements to furnish copies to Major Langguth as soon as they become available were made by this officer prior to his departure from USFET. The publication of these rules will permit resumption of the research in fundamental nuclear physics.

b. Lack of laboratory space.

Most of the universities and KWIs have been badly damaged during the war. Pictures of some of the universities and KWIs and also report of the status of KWIs and some of the universities has been placed in the file of the Washington Office. They are evidence that it will take several years to repair the laboratories to a point where a full scale research can be resumed.

c. Lack of equipment.

Much of the laboratory equipment has either been destroyed during the war, removed from its original laboratory location or deprived of essential peices by looting.

d. Lack of auxilliary laboratory materials.

All glassware used in chemical laboratories before the war came from what is now the Russian Zone of Germany and, therefore, continued supply at the present time is not available. In addition, just ordinary chemicals used in laboratory research are either unavailable or extremely hard to procure.

e. Lack of time.

Much of the efforts and time of the present faculties and students not taken up in class work is occupied with the repair and rebuilding of the laboratory buildings. It is not at all unusual to see the students hanging windows, plastering walls, repairing doors, floors, etc.

f. Lack of personnel.

Many of the younger men who would normally be available to serve as research assistants are not available as helpers in conducting research. Most of these young fellows were members of the Nazi party and as yet have not been cleared to resume their professional work. The same is true of some of the older (like Prof. Brill at Darmstadt and Prof. Kirchner at Garmisch) are kept from teaching until their party records have been received by the Spruchkammer (Denazification Boards) and their reinstatement in teching job approved by the faculty of the institution. In the meantime student enrollment is up over 50% above pre-war.

F. Laboratory Equipment

1. In letter dated 12 August 1946 Lt. Col. Edgar P. Dean transmitted to the Washington Office information obtained by the undersigned on the locations and operating characteristics of the special types of laboratory equipment usable for nuclear research. The following is a tabular summary of the types of equipment and their locations:

Heidelberg

- 1 cyclotron
- 1 betatron (disassembled and incomplete)
- 1 van de Graaf machine

Erlangen

- 1 betatron (disassembled)
- 2 betatrons (incomplete)

Hamburg

- 1 betatron (disassembled)

Göttingen

- 1 mass spectograph.

2. Late in August 1946 OMGUS informed USFET G-2, in answer to the latter's letter of 9 July 1946, that resumption of fabrication and assembly of the three 6 Mev betatrons at Siemens-Reiniger Werke, Erlangen would take place as rapidly as possible. (Picture of betatron and its parts have been procured for the Washington file.) As soon as estimated completion dates are furnished USFET G-2, the latter will cable the information to the War Department and make recommendations on their disposal.

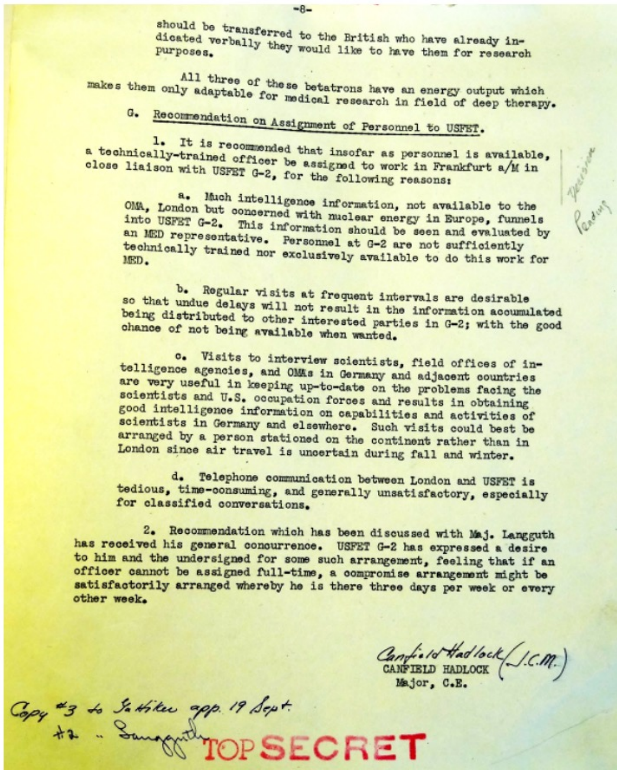
3. It is the recommendation of the undersigned that the first betatron completed be transferred to the British for use by Prof. Kopfermann in the Frauenklinik, Göttingen, (This instrument was actually on order for this institution at the time when fabrication was stopped by order of OMGUS); and that the other two betatrons be disposed of according to one of the following alternative suggestions given in order of priority:

(1) They should be offered to FIAT for research in the American Zone.

(2) If FIAT cannot use them to advantage, they should be offered through the War Department to U. S. institutions for research.

(3) If neither (1) nor (2) develops a use for them, they

Decision Ask Fields
to Fields 24 Aug



-8-

should be transferred to the British who have already indicated verbally they would like to have them for research purposes.

All three of these betatrons have an energy output which makes them only adaptable for medical research in field of deep therapy.

G. Recommendation on Assignment of Personnel to USFET.

1. It is recommended that insofar as personnel is available, a technically-trained officer be assigned to work in Frankfurt a/M in close liaison with USFET G-2, for the following reasons:

Decision Pending

a. Much intelligence information, not available to the OMA, London but concerned with nuclear energy in Europe, funnels into USFET G-2. This information should be seen and evaluated by an MED representative. Personnel at G-2 are not sufficiently technically trained nor exclusively available to do this work for MED.

b. Regular visits at frequent intervals are desirable so that undue delays will not result in the information accumulated being distributed to other interested parties in G-2; with the good chance of not being available when wanted.

c. Visits to interview scientists, field offices of intelligence agencies, and OMAs in Germany and adjacent countries are very useful in keeping up-to-date on the problems facing the scientists and U.S. occupation forces and results in obtaining good intelligence information on capabilities and activities of scientists in Germany and elsewhere. Such visits could best be arranged by a person stationed on the continent rather than in London since air travel is uncertain during fall and winter.

d. Telephone communication between London and USFET is tedious, time-consuming, and generally unsatisfactory, especially for classified conversations.

2. Recommendation which has been discussed with Maj. Langguth has received his general concurrence. USFET G-2 has expressed a desire to him and the undersigned for some such arrangement, feeling that if an officer cannot be assigned full-time, a compromise arrangement might be satisfactorily arranged whereby he is there three days per week or every other week.

GERMAN SUPERSONIC SPEED ROCKET. This large anti-aircraft rocket called "Rheintochter" was under final development at the end of the war—a forerunner of future "push-button warfare." It was remotely controlled by radio and carried a 330-lb. explosive charge activated by a proximity fuse. [...]

Germany's Plans for the "A-9" with Atomic Bomb

The range of the V-2 was only something over 200 miles but this was sufficient to reach all intended targets at that time. The German scientists, however, had not stopped with the V-2. During 1945 they had already built at Peenemünde (in the hands of the Russians since that time) several "A-9's". This was a winged V-2, either manned or unmanned, and intended for a range of around 3,000 miles with the aid of a large auxiliary launching rocket. Together the launching rocket and the A-9 weighed 110 tons, as compared with 13½ tons for the V-2. After the auxiliary launching rocket had accomplished its purpose and dropped off, the A-9 was designed to continue under its own power wholly outside the earth's atmosphere at an altitude of approximately 150 miles, and at an estimated speed of 5,800 miles per hour. This obviously would mean an Atlantic crossing in well under an hour's time, and a launching ramp had already been constructed in Normandy prior to the Allied invasion.

In captured scientific German documents there are diagrams of the city of New York showing anticipated areas of destruction to be expected after perfection of such a weapon to carry an atomic war head, and it is well known that the Germans originally had hoped to have their atomic bomb developments completed by the end of 1944. The Germans had many other advanced developments in guided missiles, but the V-2 was an actual accomplishment and its further development for long range was just a matter of time. Meanwhile all the allied nations have recourse to the captured German documents describing their future plans for these weapons and many of the former German scientists responsible for these developments are known to be continuing their work in each of the allied countries. Adequate defense against such weapons as the V-2 and the A-9 will require highly ingenious and supersonic defensive weapons, and no country can afford to forego the necessary expense for basic and applied research to that end.

[See document photos on p. 5073. Woods was not merely speculating in the above text; he was writing from a position of very well-informed authority. He was a colonel in the Air Technical Services Command (ATSC)/Air Materiel Command (AMC), serving as an intelligence officer in Europe during World War II and helping to collect and analyze captured German research after the war (probably working for Donald Putt). After writing this book, he went on to become Assistant to the Undersecretary of the Air Force 1947–1950.

See for example: George B. Woods, Former Assistant to Air Undersecretary. *Evening Star* (Washington, D.C.), 5 March 1954, p. A-12. https://chroniclingamerica.loc.gov/lccn/sn83045462/1954-03-05/ed-1/seq-12/

For similar statements from other sources, see pp. 4411 (paragraph 15), 4638, 5022, 5031, 4832, and 5821.]

D.14.10 Fritz Lang and the Leak That Almost Revealed Everything

[The famous German film director Fritz Lang (1890–1976, p. 1971) moved to the United States in 1933 and continued making movies there.[19] In 1946, Lang directed the film *Cloak and Dagger* for the Warner Bros. studio. *Cloak and Dagger* presented a fictionalized story of how during World War II, OSS and European resistance members investigated and combatted the German nuclear weapons program. As scripted and filmed, the movie ended with a visually impressive and highly expensive sequence in which U.S. forces bomb several German nuclear weapons factories and visit another one in person. However, before the film was released, that entire sequence was censored and apparently destroyed, leaving a short final film that focuses on personal melodrama and avoids any mention or depiction of German nuclear weapons factories.

Although *Cloak and Dagger* was fiction, Lang's story descriptions and the script versions included an extraordinary number of details that agree stunningly well with real information about the German nuclear weapons program (as presented elsewhere in this appendix) which was not publicly known in late 1945/early 1946 when the film was being written and shot, including for example:

- The German program completed construction of fission bombs (e.g., pp. 4182, 4436, 4635, 4666–4667, 4903).
- Germany successfully tested the bombs (e.g., Sections D.10, D.11, D.12).
- Germany was developing vehicles to deliver those bombs to Allied targets (e.g., Appendix E).
- Even in the final weeks of the war, Germany could have dramatically changed the war by using those weapons (e.g., pp. 4572–4681, 4703–4712, 4766, 5022–5039, 5072–5073).
- The German nuclear weapons program was divided among a number of sites in German-controlled territory (e.g., pp. 3671–3677, 4400–4403).
- Many of those sites were underground facilities (e.g., pp. 3874–3920, 4176–4182, 4400–4403, 4504–4519, 4568–4570, 4636, 4962–4970, 4985–4991).
- The German nuclear program used many thousands of slave laborers (e.g., pp. 3874–3920, 4176–4182, 4400–4403, 4440–4477, 4636, 4974).
- Many of the slave laborers actually lived underground full-time, instead of in nearby camps on the surface (e.g., pp. 3874–3922, 4400–4403, 4504–4510, 4974).
- Most of the slave laborers were killed by the end of the war (e.g., pp. 3874–3920, 4440–4570).
- At least one of the major sites was near Grünbach (in the 12 June 1946 final script by Ring Lardner Jr. and Albert Maltz), which is next to Johanngeorgenstadt in the uranium-rich Erzgebirge mountains of Saxony (e.g., pp. 3416, 3424, 3426–3428, 3433–3437, 3456, 3468–3469, 3708, 4922).[20]
- At least one of the major sites was in the vicinity of Linz, Austria (Bad Hall in the final script) (pp. 3874–3920, 4962–4970).

---

[19] Bogdanovich 1967; Eisenschitz and Bertetto 1994; Eisner 1977; Jenkins 1981; McGilligan 1997.

[20] Some versions of the *Cloak and Dagger* script mistakenly indicated that Grünbach was in Bavaria. It is near the Bavaria-Saxony border but on the Saxony side.

- At least one of the major sites was in the Netherlands (Kaptein in the final script) (e.g., pp. 4314–4316, 4832–4852).
- At least one of the major sites was in southern Bavaria (Bad Tölz in the final script) (e.g., pp. 3473, 3871–3873).
- At least one of the major sites was in Czech territory (e.g., pp. 3749, 3689–3782, 3979–4022, 4914–4922, 4974–4984, 5503–5566, 5696), specifically near Bodenbach (pp. 3987–3998) in the 24 November 1945 screenplay outline by John Larkin and Boris Ingster.
- At least one of the major sites was on the Baltic coast in the outline (e.g., Section D.10).
- At least one of the major sites was a few tens of kilometers south of the Baltic coast of Germany in the outline (e.g., pp. 3694, 4176–4182, 4679).
- OSS had a major program to investigate the progress of German nuclear weapons development (Azusa, e.g., pp. 3747–3749, 4400–4403, 4670, 5044–5048).
- U.S. intelligence and European resistance members informed senior U.S. government officials about the advanced state of the German nuclear program (e.g., pp. 4703–4707, 4832–4852, 5012, 5022, 5031, 5072–5073).
- U.S. intelligence and European resistance members informed the U.S. government about some of the major sites of the German nuclear program, and those were targeted by Allied bombing raids (e.g., pp. 3334, 3617, 3928, 3979, 4068, 4411, 4679, 5199).
- Allied forces rushed to some of the remaining German nuclear sites at the end of the war and found that those sites had already been abandoned (e.g., Section D.14.7).
- German nuclear scientists and their technologies were establishing nuclear weapons programs in other countries after the war (e.g, Section 8.9).

It is theoretically possible it was just a sheer coincidence that the *Cloak and Dagger* scripts bore so many similarities to the real German nuclear weapons program. Yet because of the number, the level of detail, and the then-classified nature of those similarities, a pure coincidence seems highly unlikely. It is far more probable that Fritz Lang received information about the real German nuclear weapons program from one or more sources:

- Advisors who were in or had close ties to western Allied intelligence, such as Michael Burke (OSS), Andries Deinum (OSS/Dutch resistance), Corey Ford (OSS), Alastair MacBain (OSS), Milton Sperling (WWII intelligence and Jack Warner's nephew-in-law), an unnamed Los Alamos scientist who was an advisor for the film, etc.
- Friends who were members of or had close ties to members of wartime German rocket-related programs (including their intended nuclear payloads), such as Willy Ley, Hermann Oberth, any members of a whole generation of German-speaking rocket engineers that grew up inspired by Lang's *Frau im Mond* (1929), or other German-speaking scientists.[21]
- Writers, advisors, or friends who may potentially have had ties to Soviet, French, Spanish, or other European intelligence sources, such as Alvah Bessie, Ben Maddow, John Gates, John Larkin, Boris Ingster, Ring Lardner Jr., Albert Maltz, etc.

---

[21] Herbert Wagner arrived in the United States in May 1945, Wernher von Braun and others arrived in September 1945, and many more members of the wartime German programs came after that.

The decision to censor the final part of *Cloak and Dagger* was delivered to Fritz Lang by Milton Sperling, Jack Warner's nephew-in-law. Although biographies of Lang (see the following pages) speculate that decision originated within the Warner Bros. studio and was made for one reason or another, that seems unlikely. If the studio had had any serious reservations about the scripted ending, they would not have kept essentially that same ending throughout numerous script versions from 1945 and 1946, and they certainly would not have invested the lavish amounts of money, resources, and time that they did to film that ending. And after having already invested so much and receiving what by all accounts was a visually and dramatically spectacular final third of the film, the studio would naturally want to benefit from that. *Cloak and Dagger* released complete with its final third would impress audiences much more and make far more money than *Cloak and Dagger* released with only its more mundane first two-thirds that lead nowhere.

Thus it seems likely that the decision to censor the film originated outside the Warner Bros. studio. Conceivably that decision could have come from almost anywhere within the U.S. government. In practice, major censorship decisions regarding nuclear weapons in general, and knowledge of the wartime German nuclear weapons program in particular, were typically handled by the office of Leslie Groves. There are a number of examples of Groves or his office censoring and reprimanding independent investigators who uncovered evidence that the German nuclear weapons program was more advanced than had been publicly admitted (e.g., pp. 3948, 3970, 4056–4061, 4185, 4187, 4679–4681, 5017–5018, 5393–5396).

The original documents for *Cloak and Dagger* are divided between two archives:

Warner Bros. Archive
University of Southern California
900 West 34th Street, Los Angeles, CA 90089-2211
https://cinema.usc.edu/about/warnerbrosarchives.cfm
wbarchives@cinema.usc.edu

Bibliothèque du film
La Cinémathèque française
51 Rue de Bercy, 75012 Paris

http://www.cineressources.net

If Leslie Groves was involved in the decision to censor the film, documentation of that fact may (or may not) be included in his papers at NARA College Park:

NARA RG 77, Entry UD-22A (General Records), Boxes 160–177. Manhattan Engineer District Foreign Intelligence Section.

NARA RG LRG. Leslie R. Groves Papers, 1941–1970.

Can future researchers identify what sources (if any) provided real information about the German nuclear program for the film?

Can future researchers identify where the orders to censor the ending originated?]

Peter Bogdanovich. 1967. *Fritz Lang in America.* New York: Praeger. pp. 15, 69–71.

[*The following is an edited version of an interview with Mr Lang tape-recorded at his home in Beverly Hills, California, over a period of six days in August–September, 1965.*] [...]

CLOAK and DAGGER (1946)

Did you have much interference on this picture?

Yes and no. [...]

But the most significant thing in *Cloak and Dagger* was the ending. It now ends with the Italian scientist being saved by the Underground: the British airplane lands and the American O.S.S. man (who was built around the characteristics of Oppenheimer) has completed his mission; the plane flies away, the girl waves, he waves, and you know they will see each other again after the war. In the original ending, the Italian scientist dies of a heart attack on the plane and all they have left to go on is an amateur photo of the scientist and his daughter with a very peculiar mountain formation in the background. The U.S. and British secret services get together and they decide, 'That can only be in Bavaria.' So they go there (I *shot* all these things, you know, parachutists, everything) and they find a camouflaged highway and then a big electrified barbed-wire fence. They're very careful but the power has been cut off. They find pill boxes and everything—all deserted—and finally they come to a big cave that is empty. All the machines are gone. (You see, we already knew the Germans had experimented with heavy water to get Atomic power—and we knew there was a plant in Norway—but, remember, Los Alamos was still hush-hush.) Then there was a conversation and they decide, 'Probably the plant is in Argentina now—or somewhere.' A sergeant comes to report that 60,000 slave workers have been found dead underneath the cave. Gary Cooper walks outside and at the entrance of the cave is a parachutist—an American boy chewing on a blade of grass. The sun is shining, birds singing. And Cooper says *something* like: 'This is the Year One of the Atomic Age and God help us if we think we can keep this secret from the world, and keep it for ourselves.' And *this* was why I wanted to make the picture. The whole reel was cut out. I don't think it exists any more.

Do you know why it was cut?

You must ask Warners, I don't know. Maybe because it was after Hiroshima and Nagasaki.

[...] I had the help of two O.S.S. people on the film—Mike Burke and a man named Deinum.

Lotte H. Eisner. 1977. *Fritz Lang.* Oxford: Oxford University Press. pp. 272, 274.

[...] The film as it now exists ends here on this equivocally happy ending. In the original version as filmed, Polda dies in the plane just as he is about to reveal to Jasper the locations of the four main plants where the Nazi atomic bomb is being tested. Unable to finish, he takes a photograph from his pocket just as he dies. It shows him and his daughter in a lake landscape with wooded hill and unusual mountain formation in the background. From this the OSS are able to identify the fourth plant, the only one Polda had not named, as Grünbach in Bavaria.

An operation is mounted. Mysteriously, RAF reconnaissance planes sent in advance encounter no resistance. When Jasper and the task force arrive, they find the secret factory is deserted. Where is the work on the bomb being continued? In Spain? The Argentine?

It was at this point that Jasper made the speech which was for Lang the *raison d'être* of the film:

> God have mercy on us if we ever thought we could really keep science a secret—or even wanted to. God have mercy on us if we think we can wage other wars without destroying ourselves . . . And God have mercy on us if we haven't the sense to keep the world in peace.

Emerging from the cave that leads to the underground factory, Jasper takes a deep breath, then sees a paratrooper tossing pebbles and gazing at the sky. [...]

As usual Lang surrounded himself with experts for the preparation of this film. Two former OSS men gave him advice based on their own cloak-and-dagger experiences during the war—Milton Sperling, the producer, and Mike Burke who had actually had the task of smuggling out of Italy an Italian admiral who had invented an electronic torpedo device which the Allies wanted to prevent the Fascists from having.

Patrick McGilligan. 1997. *Fritz Lang: The Nature of the Beast.* London: Faber and Faber. pp. 333-334, 339–340.

Cloak and Dagger was based on a book by Corey Ford and Alastair MacBain, "the inside story of General Bill Donovan's famous O.S.S,"[....]

Two sets of writers—first Ben Maddow and John Gates, followed by Boris Ingster and John Larkin—had labored on the OSS scenario for several months before Lang was hired in November [1945]. [...]

Lang had just been put in charge when [Ring] Lardner [Jr.] came aboard. Lardner's mission was to accomplish, at improbable speed, a marriage of earlier, unsatisfactory drafts. The screenwriter recalled a series of agreeable meetings with Lang, mostly at the director's house, in which the two hashed over the revisions. [...]

[Albert] Maltz also met with Lang on a regular basis throughout January, but wrote his scenes separately from Lardner, concentrating on punching up the last third of the film. [...]

None of these writers was a reporter, so an expert had to be brought on to authenticate the spy-trappings. Michael Burke was the real thing. A former University of Pennsylvania all-American football player who had been with the OSS, Burke, in one famous exploit, had helped smuggle an anti-Nazi admiral out of Italy. Hired as technical adviser, Burke ventured a few sensible suggestions, and found himself gratefully "adopted" by Lang.

Andries Deinum also added a bit of expertise to the project. A native Dutchman and a friend of Milton Sperling's, Deinum also had OSS experience. At first employed as Sperling's assistant, an intermediary for the producer with Lang, Deinum also found a kinship with the director and was "adopted" by him. In part that was because Deinum was a young man just starting out in the business, in part because he was versed in German language and culture. [...]

Burke and Deinum became frequent dinner guests at Lang's house[....]

The *Cloak and Dagger* script had to be hastily finalized as the first week of photography approached in March 1946. [...]

The final scene in the released version of *Cloak and Dagger* is not the ending Lang preferred—and not the one he filmed. This, too, became a sort point in his memory.

In the last scene as the film stands, Professor Jasper manages to elude death on the ground in Italy. He escapes by boarding a plane with an elderly scientist defector. But this was yet another "happy ending" foisted on Lang. It had been augmented in the original script by an epilogue in which the scientist dies on the plane from a heart attack brought on by the stress of events. A snapshot in his pocket then provides the only clue to the whereabouts of a fascist atom-bomb factory in the Bavarian Alps.

The last scene was intended to be one of Fritz Lang's superclimaxes: the American going back on one final secret errand, determined to destroy the German atomic-bomb factory. [...]

Milton Sperling, Michael Burke, Andries Deinum, Willy Ley, and another adviser on the picture—a scientist from Los Alamos—all tried to talk Lang out of the scene on the principle that nothing of that sort had transpired during the war. Everyone knew the Nazis had fallen short of atomic capacity. Lang, only interested in authenticity when it served his purposes, was adamant. He wanted to make a statement against war and weapons of mass destruction. The producer, still bargaining for long-term goodwill, decided the wise thing to do would be to let the director have his way.

Lang took Gary Cooper and everybody out to Bronson Canyon, where Warner Brothers had built an imitation bomb factory and where for several days they filmed the superclimax—adding thousands upon thousands of dollars in budget costs. Planes flew overhead, paratroopers dropped from the skies, the bomb factory blew up for the cameras.

According to a plot synopsis prepared by the studio publicity department, this is how Lang's version would have ended: "They have come too late. The factory has been thoroughly stripped by the Germans, its equipment probably moved to Spain or Argentina, where the Nazis had a foothold. The picture ends with the lines of the American scientist [Professor Jasper]: 'God have mercy on us if we think we can keep science a secret! God have mercy on us if we think we can wage other wars without destroying ourselves.'"

After showing a rough cut to Warner Brothers executives in late August [1946], however, Sperling decided to drop the expensive and historically dubious sequence.

D.14.11 Allied Intelligence Officials Who Would/Should Have Known

[There are a number of Allied intelligence officials who would/should have known about the German nuclear weapons program, and whose files may reveal useful information if any relevant documents in them could be located, declassified, and released:

> Commander Herbert Agar (1897–1980), assistant to the U.S. ambassador to Great Britain (pp. 5017–5018).
>
> Civilian investigator Jack H. Alberti (??–??), U.S. Navy intelligence.
>
> Colonel Robert S. Allen (1900–1981), U.S. Army.
>
> Dr. Luis Walter Alvarez (1911–1988), Manhattan Engineer District.
>
> General Henry H. Arnold (1886–1950), U.S. Army Air Forces.
>
> Colonel Peter Beasley (1884–1957), U.S. Army Air Forces, Strategic Bombing Survey.
>
> Dr. Hans Bethe (1906–2005), Manhattan Engineer District (p. 5005).
>
> General Thomas J. Betts (1894–1977), Supreme Headquarters Allied Expeditionary Force, Assistant Chief of Staff for intelligence.
>
> General Clayton L. Bissell (1896–1972), U.S. Army Air Forces intelligence.
>
> Dr. Edward L. Bowles (1897–1990), MIT and advisor for General Henry Arnold.
>
> A. E. Britt (??–??), affiliation?
>
> Dr. Vannevar Bush (1890–1974), Director of Office of Scientific Research and Development (OSRD)/National Defense Research Committee (NDRC)
>
> Major Horace K. Calvert (1915–2006), U.S. Army/Manhattan Engineer District intelligence.
>
> Dr. Karl P. Cohen (1913–2012), Manhattan Engineer District.
>
> Dr. James B. Conant (1893–1978), Assistant Director of Office of Scientific Research and Development (OSRD)/National Defense Research Committee (NDRC)
>
> General George Bryan Conrad (1898–1976), Supreme Headquarters Allied Expeditionary Force, Assistant Chief of Staff for intelligence.
>
> Captain George C. Davis (??–??), U.S. Army/Manhattan Engineer District intelligence.
>
> Colonel Howard W. Dix (??–??), Office of Strategic Services.
>
> General William Donovan (1883–1959), Office of Strategic Services Director.

Allen Dulles (1893–1969), Office of Strategic Services senior agent and later Central Intelligence Agency Director.

Colonel George R. Eckman (??–1971), U.S. Army Counter Intelligence Corps and Alsos Mission Executive Office.

G. Verner Edlund (1906–2004), U.S. Army Counter Intelligence Corps.

Major Ernst Englander (??–??), U.S. Army Air Forces.

Dr. Richard Fischer (1910–1991), U.S. Geological Survey (p. 3948).

Dr. Victor H. Fraenckel (1908–1998), Scientific Intelligence Advisory Section (SIAS) for Supreme Headquarters Allied Expeditionary Force (SHAEF); one of Dwight Eisenhower's highest-level science advisors.

Major Robert R. Furman (1915–2008), U.S. Army/Manhattan Engineer District intelligence.

Colonel Dale M. Garvey (1914–2002), U.S. Army Counter Intelligence Corps.

David Gattiker (??–1993), U.K. Atomic Energy Office.

Dr. Samuel Goudsmit (1902–1978), Alsos Mission scientific head. [Did he really not know about the much larger and much more advanced parts of the German nuclear program, or did he just publicly pretend not to know? Many of his files are still classified and not available to scholars. Why?]

General Leslie Groves (1896–1970), U.S. Army/Manhattan Engineer District commanding officer.

Caperton Horsley (1903–1988) , civilian CIOS investigator (pp. 3957–3970).

General John Edwin Hull (1895–1975), U.S. Army.

Justice Robert H. Jackson (1892–1954), U.S. Prosecutor, Nuremberg trials.

Dr. Theodore von Kármán (1881–1963), chief scientific advisor for Henry Arnold and U.S. Army Air Forces.

Colonel John A. Keck (??–??), U.S. Army Ordnance.

Colonel Oscar Koch (1897–1970), U.S. Army intelligence.

General Egmont F. Koenig (1892–1974), U.S. military attaché in Czechoslovakia from January 1946 to May 1947.

Dr. Gerard P. Kuiper (1905–1973, p. 803), Alsos Mission.

Colonel John Lansdale, Jr. (1912–2003), U.S. Army/Manhattan Engineer District intelligence.

General John Magruder (1887–1958), Office of Strategic Services Deputy Director.

General George C. McDonald (1892–1969), U.S. Army Air Forces intelligence.

General Joseph T. McNarney (1893–1972), U.S. Army Air Forces.

Dr. Philip Morrison (1915–2005), Manhattan Engineer District.

Dr. John von Neumann (1903–1957), Manhattan Engineer District (p. 5005).

Dr. Todos M. Odarenko (1900–1975), AT&T Bell Laboratories.

Lt. Colonel John A. O'Mara (19??–19??), U.S. Strategic Air Forces in Europe, Office of the Director of Intelligence.

Dr. J. Robert Oppenheimer (1904–1967), Manhattan Engineer District (p. 5005).

Dr. Richard W. Porter (1913–1996), General Electric rocket programs.

General Donald Putt (1905–1988), U.S. (Army) Air Force.

General William L. Richardson (1901–1973), U.S. (Army) Air Force.

Dr. Howard P. Robertson (1903–1961), Chief of the Scientific Intelligence Advisory Section (SIAS) for Supreme Headquarters Allied Expeditionary Force (SHAEF); Dwight Eisenhower's highest-level science advisor.

Lt. Vladimir L. Rychly (1909–1992), U.S. Navy intelligence and U.S. military attaché in Czechoslovakia

A. J. Saxon (??–??), Manhattan Engineer District.

Whitney Shepardson (1890–1966), Office of Strategic Services.

Colonel W. R. Shuler (??–??), U.S. Army/Manhattan Engineer District intelligence.

General Edwin L. Sibert (1897–1977), U.S. Army intelligence and Central Intelligence Group.

Colonel Leslie E. Simon (1900–1983), U.S. Army.

Major Francis J. Smith, (??–??), U.S. Army/Manhattan Engineer District intelligence.

Dr. Charles P. Smyth (1895–1990), Princeton and Alsos Mission (p. 4788).

General George V. Strong (1880-1946), U.S. Army, commander of the Military Intelligence Corps.

Dr. Edward Teller (1908–2003), Manhattan Engineer District (p. 5005).

Major Edmund Tilley (1892–1966), U.K. military intelligence (pp. 4894–4895).

Dr. Richard C. Tolman (1881–1948), Manhattan Engineer District.

Major H. S. Traynor (??–??), Manhattan Engineer District.

Dr. Major John E. Vance (1905–1975), U.S. Army/Manhattan Engineer District.

Joseph Volpe, Jr. (1914–2002), U.S. Army/Manhattan Engineer District.

Frederic A. C. Wardenburg III (1905–1997), Alsos Mission.

Colonel Lowell P. Weicker (1903–1978), U.S. Strategic Air Forces in Europe, Office of the Director of Intelligence.

Major P. M. Wilson (??–??), Dustbin interrogation center.

Colonel George Bryant Woods (1896–1954), U.S. Air Technical Services Command (ATSC)/Air Materiel Command (AMC) intelligence, and later Assistant to the Undersecretary of the Air Force.

Are there other people who should be included here???

Intelligence sources or agencies for the United States, United Kingdom, France, Soviet Union, and Netherlands have already been mentioned. Was useful information on the German nuclear weapons program handled by intelligence agencies or spy networks in other countries—Norway, Sweden, Denmark, Belgium, Luxembourg, Switzerland, Poland, Czechoslovakia, Hungary, etc.?]

D.15 Analysis of Current Evidence; Recommended Further Work

Based on information from the sources regarding wartime German nuclear work that were quoted in the earlier sections of this appendix, this section analyzes:

D.15.1. Overarching programmatic considerations.

D.15.2. Uranium-235 enrichment methods.

D.15.3. Plutonium-239 or uranium-233 breeding methods.

D.15.4. Test explosions.

D.15.5. Design parameters of the tested devices.

D.15.6. Evidence for other device designs.

D.15.7. Conclusions and recommendations for further historical research in this area.

D.15.1 Overarching Considerations Regarding the German Nuclear Program

This section summarizes the known and extrapolated characteristics, secrecy, timeline, and organization of the wartime German nuclear weapons program. As instructive references, that program is compared to other wartime German programs on revolutionary new weapons technologies, as well as to the wartime U.S. nuclear weapons program.

A. Characteristics of the German Nuclear Program

The conventional historical narrative is that the wartime German nuclear program was very small, poorly funded, and badly misguided both scientifically and politically, and that as a result it never accomplished much.[22] On the other hand, the conventional historical view does recognize that other revolutionary German military programs such as those for rockets, jets, and chemical warfare agents were large and accomplished a great deal.[23] While currently available information on the German nuclear program is very incomplete, the data from the key sources quoted earlier in this appendix does not match the picture of a small and inconsequential program, but rather a large and advanced nuclear program quite comparable to the most successful German programs such as those on rockets, jets, and chemical warfare agents:

1. A large nuclear program would have begun with early theoretical research and proof-of-concept experiments. For example, in order to test their earlier designs and calculations, Wernher von Braun's team began experimenting with rockets in 1932 at Kummersdorf. Hans von Ohain began experimenting with jet engines in 1935 at Göttingen and then at Heinkel. Gerhard Schrader produced the first organophosphate nerve agents in 1936.
    (a) Fritz Houtermans was doing work on nuclear fusion at least as early as 1928 [Atkinson and Houtermans 1929a].
    (b) Rausch von Traubenberg, Arno Brasch and Fritz Lange, and others were conducting laboratory experiments with nuclear fusion reactions from 1933 onward [pp. 4281–4282].
    (c) Ida Noddack correctly predicted nuclear fission of uranium in 1934 [Noddack 1934].
    (d) Otto Hahn and Fritz Strassmann demonstrated and explained nuclear fission of uranium in late 1938 [Hahn and Strassmann 1939].

[23] See for example: Amtmann 1988; Bohr 2013; Butler 1994, 2007; Christensen 2002; Christopher 2013; Cole 2015; Conner 2001; Constant 1980; Cooke and Ingells 1945; Daso 2002; Dornberger 1958, 1994; Dorr 2013; Duffy 2012; Erfurth 2006; Forsyth and Creek 2007; Franz 1985; Friedrich et al. 2017; Gellermann 1986; Gleichmann 2013; Gleichmann and Bock 2009; Griehl 1990, 2004, 2005, 2015; Gröhler 1989; Hager 2008; Harris and Paxman 2002; Heinkel 1956; Hellmold 1999; Herwig and Rode 2000; Hirschel et al. 2004; Hein Hofmann 2008; Hölsken 1994; Huzel 1962; Hyland and Gill 1998; Irving 1965; Jakobs et al. 2009; Jacobsen 2011, 2014; Johnsen 2014; Kaszeta 2020; Kay 2002; King and Kutta 1998; Klee and Merk 1963; Kober 1990; Leyes and Fleming 1999; Lommel 2005; Longden 2009; Masters 1982; Hans-Ulrich Meier 2010; Jürgen Michels 1997; Miranda 2015; Miranda and Mercado 1996; Myhra 1998a, 1998b, 2000a, 2000b, 2001, 2002, 2003; Neufeld 1995; Nowarra 1988; Ordway and Sharpe 1979; Pavelec 2007; Pfingsten 2003; Samuel 2004, 2010; Shepelev and Ottens 2015; Simons 2016; Smith and Creek 1992, 2001; Smith and Kay 2002; Stuhlinger and Ordway 1994a, 1994b; Stüwe 1999, 2014, 2015; Thomas 1946; Trischler 1992a, 1992b; Tucker 2006; Vajda and Dancey 1998.

2. A nuclear program would have first become a major government program shortly before or at the beginning of the war. For example, the Peenemünde rocket center was set up in 1937, Luftwaffe-funded jet programs began in 1939, and organophosphate nerve agents became a major Army-funded program in 1937.
    (a) High-level, coordinated, and secret government meetings regarding nuclear research and development began in April 1939 [Irving 1967, p. 33].
    (b) Government programs for nuclear research and development were formalized in September 1939 [Irving 1967, pp. 38–43].
3. A large nuclear program would have been given the highest priority, just as the rocket, jet, and chemical warfare programs were given high priorities by the government.
    (a) Even Samuel Goudsmit admitted that the nuclear program "had the highest priority among all scientific research projects in Germany" [Goudsmit 1945] (see pp. 3297–3298).
    (b) The nuclear program was personally directed and supported by Heinrich Himmler [Krotzky 2002].
4. A large nuclear program would have been conducted in great secrecy, just as the rocket, jet, and chemical warfare programs were.
    (a) Heinrich Himmler's chief adjutant Werner Grothmann described the entire nuclear weapons program as being kept very secret (see pp. 3396–3397).
    (b) According to Ivan Ilyichev's 23 March 1945 intelligence report: "The regime of secrecy at the test site was at maximum level. Entrance and exit from the territory are by special pass only. SS soldiers have surrounded the area of tests and interrogated any person approaching the area." (See p. 4485).
5. A large nuclear program would have vigorously pursued all possible types of nuclear weapons in parallel, just as the rocket program pursued dozens of different types of missiles, the jet program pursued all possible types of engines and aircraft, and the chemical warfare program pursued hundreds of possible nerve agents and other compounds.
    (a) According to Werner Grothmann, the German nuclear program developed bombs using uranium, bombs using plutonium, bombs that apparently incorporated fusion fuel, at least two types of large bombs for cities, at least two types of small bombs for tactical targets, air-dropped bombs, and bombs that could be delivered via rockets (see pp. 3396–3397).
    (b) As will be discussed on p. 5169, there is other evidence that a wide variety of bomb types were pursued by the German nuclear program.
6. A large nuclear program would have been conducted by a large number of groups distributed throughout German-held territory yet coordinated with each other, just as the rocket, jet, and chemical warfare programs were conducted by numerous distributed but coordinated groups throughout Germany and German-occupied territory. Like the rocket, jet, and chemical warfare programs, a large nuclear program would have had at least half of its operations

outside of Germany, and much of its German operations in areas with high concentrations of military research and development, especially on the Baltic coast, near Berlin, and in Thuringia.

   (a) Within Germany proper, nuclear work was reported at Peenemünde, Rügen, and elsewhere on or near the Baltic coast (including the occupied Danish island of Bornholm just off the Baltic coast); at the Kaiser Wilhelm Institute for Physics, Manfred von Ardenne's laboratory, Auergesellschaft/Oranienburg, Kummersdorf/Gottow, and elsewhere in the greater Berlin area; and at Stadtilm, Ohrdruf, and elsewhere in Thuringia.

   (b) A great deal of work apparently occurred outside the traditional borders of Germany, in Norway, Austria, Czechoslovakia, and Poland.

   (c) Those various activities were not independent, parallel, small-scale efforts, but rather were all funded and coordinated from the highest levels by people such as Abraham Esau and Walther Gerlach, with joint backing from the Army, SS, Reichspost, and other agencies.

7. A large nuclear program would have experienced delays caused by Allied attacks, just as the rocket, jet, and chemical warfare programs did.

   (a) The Allied sabotage and then destruction of the Vemork heavy water plant in Norway is widely regarded as a major setback for the German nuclear program [Bascomb 2016; Dahl 1999; Rhodes 1986, pp. 455–517].

   (b) Other major Allied attacks included the August 1943 bombing of Peenemünde, the 1943–1944 bombings of the Frankfurt Degussa plant, bombings of targets around Berlin, and other attacks.

   (c) The Allied attacks were credited with delaying the German programs [see for example: Arnold 1949, p. 491; Casey 1988, p. 54; Knight 1946; Putt 1946b; Thomas 1946; *Chicago Daily Tribune* 1946-01-26 p. 10; *Daily Express* 1945-08-09; *Daily Mail* 1945-06-14 p. 1; *Daily Mail* 1945-08-09; *Daily Telegraph* 1945-08-09; *NYT* 1945-08-09].

8. A large nuclear program would have conducted the first phase of its experiments in more academic settings, just as the rocket, jet, and chemical warfare programs did. In fact, nuclear work was conducted by:

   (a) Werner Heisenberg and others at the Kaiser Wilhelm Institute for Physics in Berlin.

   (b) Otto Hahn, Fritz Strassmann, and others at the Kaiser Wilhelm Institute for Chemistry in Berlin.

   (c) Josef Mattauch, Alfred Klemm, and others at the Kaiser Wilhelm Institute for Chemistry in Tailfingen.

   (d) Manfred von Ardenne, Fritz Houtermans, and others at von Ardenne's laboratory in Berlin.

   (e) Paul Harteck, Wilhelm Groth, Johannes Jensen, and others at the University of Hamburg.

   (f) Walther Gerlach, Klaus Clusius, and others at the University of Munich.
   (g) Georg Stetter, Josef Schintlmeister, Willibald Jentschke, and others at the University of Vienna.

9. A large nuclear program would then have transferred mass-production based on those results to other locations featuring heavy industry, just as the rocket, jet, and chemical warfare programs did. For the nuclear program, those locations are known or suspected to have included:
   (a) Several Degussa locations.
   (b) Several I.G. Farben locations.
   (c) AEG locations.
   (d) Siemens locations.
   (e) Other industrial locations.

10. A large nuclear program would have shifted to locations that were more remote, more dispersed, and/or underground in order to be more resistant to Allied attacks, as the rocket, jet, and chemical warfare programs did. For the nuclear program, such locations included:
   (a) Underground installations in or near the Lüneburger Heide (pp. 4176–4182 and 4406).
   (b) Numerous underground installations reported around Thuringia [Baranowski 2013; Brunzel 2013; Fäth 1999, 2000; Gleichmann and Dörfer 2011; Mayer and Mehner 2001, 2002, 2004a, 2004b; Mehner 2004; Schambach 2011; Schilling 2010; Seidler and Zeigert 2006; Wichert 1999; Zeigert 2003; CIOS XXXIII-38].
   (c) Underground installations such as Gusen, Bergkristall, and Quarz in Austria [Bouchal and Sachslehner 2013; Joseph Fisher 2017; Haunschmied et al. 2007; Köberl 1993; Perz 2014; Schmitzberger 2004; Sulzer and Brauburger 2014, 2015, 2019a, 2019b].
   (d) The large underground Weser works near Podmokly, as well as other locations in Czechoslovakia, far from Allied bombing (pp. 3979–4022).
   (e) Underground installations in Silesia (pp. 4504–4510).

11. Like the rocket, jet, and chemical warfare programs, a large nuclear program would have used large-scale slave labor, with very poor working conditions and systematic extermination of any surviving slave laborers in order to maintain security. In fact, there was mass slave labor and mass extermination at:
   (a) Underground installations in Thuringia [Baranowski 2013; Brunzel 2013; Fäth 1999, 2000; Gleichmann and Dörfer 2011; Mayer and Mehner 2001, 2002, 2004a, 2004b; Mehner 2004; Schambach 2011; Schilling 2010; Seidler and Zeigert 2006; Wichert 1999; Zeigert 2003; CIOS XXXIII-38].
   (b) Underground installations in Austria [Bouchal and Sachslehner 2013; Joseph Fisher 2017; Haunschmied et al. 2007; Köberl 1993; Perz 2014; Schmitzberger 2004; Sulzer and Brauburger 2014, 2015, 2019a, 2019b].

   (c) Underground installations in Silesia (pp. 4504–4510).

12. A large nuclear program would have been partially under SS control for most of the war (especially in occupied areas outside of Germany), and would have come under complete SS control in the final stages of the war, as the rocket, jet, and chemical warfare programs did.

    (a) Rudolf Mentzel, an SS Oberführer with a Ph.D. in chemistry, was a central figure in the government nuclear program meetings from 1939 onward. He also played a key role in facilitating the scientific leadership transition from Abraham Esau to Walther Gerlach [Irving 1967].

    (b) Werner Grothmann, Heinrich Himmler's aide, said the nuclear program was run by the SS. Other people who were close to Himmler, such as Felix Kersten, Wilhelm Wulff, and Muhammad Amin Al-Husayni, all reported that Himmler had detailed knowledge of the nuclear program.

    (c) Ivan Ilyichev's 23 March 1945 intelligence report described the nuclear weapons tests as being under very tight SS control.

13. Between extreme pressure from the SS and intense bombing from the Allies in the final stages of the war, a large nuclear program would have been racing to perfect its weapons, would have been running late, and would have achieved or been on the verge of achieving its most significant results only at the very end of the war, just as the rocket, jet, and chemical warfare programs did.

    (a) Reportedly the first successful nuclear weapons tests did not occur until the final stage of the war, between October 1944 and March 1945; see Sections D.10–D.12.

    (b) A number of sources reported that military deployment of a nuclear weapon would not have been possible until the very end of the war, or a few months beyond that if the war had continued [see for example: Knight 1946; Putt 1946b; Thomas 1946; *Chicago Daily Tribune* 1946-01-26 p. 10; *Daily Mail* 1945-06-14 p. 1].

14. In the final stages of the war, a large nuclear program would have conducted major tests of prototypes in areas with relatively low populations of Germans but with very high concentrations of high-technology military research, development, and testing, such as on the Baltic coast, in German-occupied central Europe, and in Thuringia, just as the rocket and jet programs did.

    (a) There is some evidence for a nuclear weapons test on the Baltic coast; see Section D.10.

    (b) There is also some evidence for a nuclear weapons test in German-occupied Poland; see Section D.11.

    (c) There is significant evidence for nuclear weapons tests near Ohrdruf in Thuringia; see Section D.12.

15. A large nuclear program would have been prevented by high-level bureaucratic decision making from effectively using its weapons during the final stages of the war, just as the rocket, jet, and chemical warfare programs were.

  (a) As reported by Allen Dulles on 1 April 1945: “In his conversation with Kesselring, latter said to Wolff our situation is desperate, nobody dares tell truth to Fuehrer who surrounded by small group of advisers who still believe in a last specific secret weapon which they call “Verzweiflunge” weapon [die Verzweiflungswaffe or the desperation weapon]. Kesselring believed this weapon can prolong war but not decide it, but might cause terrible blood bath on both sides. Kesselring said if Fuehrer gave him order to use weapon he would surrender his command.” See p. 4670.
  (b) Werner Grothmann said that military use of the German nuclear weapons was debated and ultimately rejected (see p. 4668).

16. At the very end of the war, a large nuclear program would have been seen by German government officials directly in charge of it more as a bargaining chip to be offered to the Allies than a weapon to be used against the Allies, just as the rocket, jet, and chemical warfare programs were.
    (a) Documents in U.S. government archives prove that Hans Kammler, who was most directly in command of the nuclear and other high-technology military programs at the end of the war, made a deal with U.S. officials, avoided war crimes trials, and was taken to the United States for extended interrogations after the war (pp. 4931–4959).
    (b) There is also evidence that Martin Bormann or other German government officials may have tried to offer German nuclear materials to the United States [Hydrick 2016].

17. A large German nuclear program that had occurred in what ultimately became Soviet-occupied areas inside and outside of Germany would have been rapidly taken over, fully exploited, and completed removed by the Soviets at the end of the war and after the war, without much opportunity for western Allied observers to learn about the wartime German program, and would have been largely concealed by Russia ever since, just as happened with the rocket, jet, and chemical warfare programs.
    (a) Soviet forces controlled and could have easily removed any nuclear-program-related personnel, materials, and information from the Baltic coast, greater Berlin area, Thuringia (after the relatively brief U.S. presence there), Poland, Czechoslovakia, Hungary, Bulgarian uranium mine, parts of Austria, northern Norway, and Bornholm island.
    (b) Other than a few highly staged and closely escorted trips, U.S. and U.K. officials were never allowed to inspect those areas, interview German scientists there, or view all of the documents and materials that the Soviets removed from those areas.
    (c) Access to virtually all of this material in Russian archives is still restricted.

18. A large nuclear program would have had a direct impact on subsequent Soviet programs, just as the rocket, jet, and chemical warfare programs did.
    (a) Many dozens of German nuclear scientists played critical roles in all major branches of the postwar Soviet nuclear weapons program, and many of them were even officially recognized with Stalin prizes for their vital contributions. Uranium captured from Germany fueled at least the first two Soviet nuclear reactors, including their plutonium production program.

   (b) The contributions of German scientists, materials, and information appear to have saved the Soviet program many years of work [Albrecht et al. 1992; von Ardenne 1990, 1997; Barkleit 2008; Barwich and Barwich 1970; Boch and Karlsch 2011; Fengler 2014; Fengler and Sachse 2012; Goncharov 1996a, 1996b; Goncharov and Riabev 2001; Graham 1993; Heinemann-Gruder 1992; Holloway 1994; Karlsch 2011; Karlsch and Laufer 2002; Karlsch and Zeman 2016; Kozyrev 2005; Kruglov 2002; Maddrell 2006; Mick 2000; Nagel 2016; Naimark 1995; Oleynikov 2000; Pondrom 2018; Riabev 1998, 2002a, 2002b, 2002c, 2002d; 2006a; 2006b; 2006c; Riehl and Seitz 1993; Siddiqi 2009; Sokolov 1955; Wellerstein and Geist 2017; West 2004; Yudin; Zeman and Karlsch 2008; *News Chronicle* 1945-10-15 p. 1; NYT 1945-10-15 p. 4, 1945-10-31 p. 6, 1946-01-29 p. 1, 1946-11-28 p. 16, 1946-12-06 p. 17, 1947-02-24 p. 1, 1948-05-26 p. 3, 1948-12-28 p. 10b; *Spokane Daily Chronicle* 1948-03-16 p. 6; *Sydney Morning Herald* 1946-04-20 p. 2; *Times* 1945-05-15, 1945-05-18].

   (c) Can the designs of Soviet advanced fission bombs (Joe-2 and beyond) and H-bombs be traced to wartime German work?

19. Any U.S. or U.K. information on a large wartime German nuclear program would have been classified and concealed (even more so than the rocket, jet, and chemical warfare programs were) in order to (i) try to hide that information or western knowledge of that information from the Soviet Union; (ii) make imported German scientists more palatable to the U.S. public and politicians (avoiding questions along the lines of "Why are we hiring scientists this month who were on the verge of nuking us last month?"); (iii) downplay wartime German technological accomplishments; and (iv) play up U.S. wartime and postwar accomplishments to both domestic and foreign audiences.

   (a) Samuel Goudsmit's job as scientific head of the Alsos Mission was to investigate the German nuclear program in great detail and report his findings, yet there is well-documented evidence that completely contradicts his public portrayal of the German program. Goudsmit appears either to have been incredibly incompetent at his assigned job or else to have been deliberately making false public statements about the German program. Here are just a few examples:

      i. Goudsmit testified to the U.S. Senate that the German nuclear scientists "were still a hundred years away from" producing a bomb at the end of the war. Just a fraction of those scientists, completely starting over in the technologically backward Soviet Union, built an atomic bomb in four years.

      ii. Goudsmit stated that "approximately 100 scientists were active on this project," and that many of those "worked only part time on this important research and the rest of the time did routine teaching or administrative work." The list of known German nuclear scientists is much larger, the total number working on the program may well have been far larger still, and the urgency and time commitment that these scientists accorded to their wartime nuclear work is documented in many of their postwar accounts.

      iii. Goudsmit claimed that Erich Schumann was "a second-rate physicist" whose "main interest was the physics of piano strings." It is well documented that Erich Schumann was the Ph.D. thesis advisor of Wernher von Braun, spent years during the war developing, demonstrating, and optimizing highly sophisticated implosion bomb designs, and was directly involved in a number of other groundbreaking military research and development programs [Nagel 2012a].

        iv. Goudsmit characterized Manfred von Ardenne as merely "a clever technician and businessman" who tried to divert government funding away from "the really competent scientists." After the war, von Ardenne was the German nuclear scientist most highly courted by the Soviet Union (presumably based on Soviet intelligence about his wartime nuclear accomplishments in Germany), and he was ultimately awarded a first class Stalin prize for helping the Soviets build their first atomic bombs [Oleynikov 2000].

    (b) A large number of Alsos-related documents from Samuel Goudsmit's files remain classified (see for example pp. 4772–4779).

    (c) Some very important Alsos-related files from the Manhattan Project's Foreign Intelligence Unit also remain classified and unavailable, as shown by the examples on pp. 4812–4827.

    (d) Numerous other files related to the German nuclear program and its scientists have been removed from the U.S. National Archives as evidenced by yellow withdrawal cards (see for example pp. 4994), or never were there yet are referenced in documents that are present.

20. A large German nuclear program would have had a direct impact on subsequent U.S. programs, just as the rocket, jet, and chemical warfare programs did.

    (a) As discussed in Section D.14.5, there is evidence that captured German enriched uranium and implosion bomb detonators may have significantly aided and accelerated the final phase of the wartime U.S. nuclear program. The United States also captured large amounts of unenriched uranium, beryllium, zirconium, and other materials that would have aided the postwar U.S. nuclear program. German-developed rockets, missile silos, jet bombers, cruise missiles, and submarines proved to be the ideal delivery methods for U.S. nuclear weapons after the war, just as they were likely intended to be delivery methods for any nuclear weapons that Germany had been developing during the war.

    (b) More archival research is needed to determine whether postwar nuclear weapons work in the United States was influenced by German nuclear scientists, materials, or information that had been found at the end of the war, especially for lighter and smaller implosion systems, high-voltage fusion neutron initiators, lithium deuteride fusion fuel, the layer cake H-bomb design, two- and three-stage H-bomb designs, and improved U-235 enrichment methods. Evidence such as the U.S. capture and interrogation of Hans Kammler (pp. 4931–4959), Edward Teller's invitation to Siegfried Flügge (p. 4996), files on German fusion research (Section D.9), and redacted or missing files from German scientists (e.g., p. 4994) raise very serious questions that deserve to be thoroughly investigated.

B. Secrecy of the German Nuclear Program

It seems reasonable to expect that any German nuclear weapons program would have had secrecy equal to or greater than that of the German chemical weapons program. The chemical weapons program developed revolutionary nerve agents, operated highly specialized research and manufacturing facilities all over German territory, created and tested dozens of different nerve agents, produced and stockpiled over 12,000 tons of nerve agents, and developed and stockpiled a wide variety of rockets, bombs, and other delivery methods that were specifically designed for those agents.

Despite the enormous size and strategic implications of this German chemical weapons program, Allied intelligence, military forces, and leaders were essentially unaware of the existence of the program and the nerve agents until the war was over [Tucker 2006, pp. 49, 55, 85–86]:

> Because of the elaborate counterintelligence measures designed to protect the secrecy of Tabun and Sarin, the Allies remained unaware of these dramatic developments. A U.S. intelligence report in July 1942 titled "New German Poison Gas" reads as follows: "Disclosures relative to so-called 'Blau Gas' have occurred numerous times in the past and... are no longer seriously regarded. Intelligence reports lend considerable weight that new German agents are not of the nature of so-called nerve gases." In hindsight, this assessment could not have been more wrong. [...]
>
> On May 11, 1943, the British captured a German Army officer in Tunisia. Under interrogation, he revealed that he was a chemist who had done chemical weapons research at Spandau Citadel in Berlin. He described the development of a new warfare agent that was colorless, had little odor, and possessed "astounding properties." Minute doses made the pupils shrink to pinheads and constricted the bronchial tubes, causing an asthmalike shortness of breath, and higher doses were lethal within fifteen minutes. [...]
>
> The British interrogators judged the prisoner's information to be reliable and wrote a ten-page secret report that was sent on July 3, 1943, to Military Intelligence in London and the Chemical Warfare Experimental Establishment at Porton Down. [...] Because of a lack of corroborating evidence, however, British officials had doubts about the veracity of the intelligence report and decided to take no action. [...]
>
> On April 23 [1945], a CIOS chemical weapons team consisting of ten British and nine American and Canadian specialists, led by Commander A. K. Mills of the British Ministry of Aircraft Production, examined the unidentified German munitions. With the cooperation of German chemists from Raubkammer who had been taken into custody, British experts from the Chemical Defence Experimental Establishment at Porton Down analyzed the contents of one of the German 250-kilogram bombs. [...]
>
> According to the scientists' laconic report, "The shells were found to contain a markedly potent and hitherto unknown organophosphorus nerve agent." [...]
>
> The realization that the Germans had secretly developed and produced a new chemical warfare agent of unprecedented power came as a terrible shock to the Allies. Although a few intelligence reports from 1943 and 1944 could be interpreted in retrospect as having referred to a German nerve agent, they had contained no firm evidence or tangible clues about its composition.

Even though in April 1945 the U.S. Alsos Mission captured and interrogated Richard Kuhn, one of the top brains of the nerve agent program, they learned nothing about the program or his role in it, and they let him go. Moreover, even when they found Kuhn again in September 1945 and pressed him for more information, all they learned was that he had been involved in the production of plastics and other basic materials. (See p. 3316.)

One of the main reasons that security in the chemical weapons program was so effective was that knowledge was highly compartmentalized. Despite the huge numbers of scientists and workers involved in the program, each of them knew only enough to do their own job, and no more. In fact, the program was so compartmentalized that Richard Kuhn, who invented many of the nerve agents such as Soman, and Gerhard Schrader, who invented many other of the nerve agents such as Tabun and Sarin, were completely unaware of each other's work [Tucker 2006, pp. 48–49, 62–63]:

> All aspects of life at Dyhernfurth were overshadowed by elaborate security measures. Access to the site was strictly controlled and required passing through a series of heavily guarded perimeters and checkpoints. In addition, the technical details of the Tabun manufacturing process were classified and the "need to know" principle was strictly enforced: factory personnel were informed only about those operations in which they were directly involved. Although IG Farben chemists and engineers were naturally curious about other aspects of the production process, they did not ask their colleagues too many questions for fear of being informed on or suspected of espionage, which could result in interrogation and torture by agents of the Geheime Staatspolizei (abbreviated Gestapo), or secret state police. [...]
>
> German counterintelligence officials also developed elaborate methods to conceal the nerve agent program from foreign intelligence services. Tabun was given a variety of cover names [...], while Sarin was referred to as "Gelan III" or "Trilon 46." Chemical ingredients used in the manufacture of Tabun were also designated with code names to make it harder for enemy spies to track shipments. [...] Whenever an ingredient for Tabun arrived at Dyhernfurth, it was assigned another local code name, making correct identification nearly impossible if the plant and its records were to fall into enemy hands. The code-name system also had the effect of keeping most of the technical staff in the dark about the precise chemical reactions involved in the manufacture of Tabun. [...]
>
> [D]uring the spring of 1944, Richard Kuhn, working at the Kaiser Wilhelm Institute in Heidelberg, made a striking discovery. He was continuing his research for the German Army by screening a wide variety of organophosphorus compounds—some of which he had synthesized himself—for the ability to inhibit cholinesterase. Because of the Nazi obsession with secrecy, his research was "compartmented": he was not put into contact with other scientists in the nerve agent field and was completely unaware of Schrader's work.
>
> When Kuhn replaced the isopropyl alcohol used to make Sarin with a more complex alcohol known as pinacolyl, the resulting substance (which he called Compound 25075) had a camphorlike odor and was roughly twice as potent as Sarin in inhibiting cholinesterase. The War Office code-named this new compound "Soman" [...]

For more information on how such highly compartmented security was the usual practice for secret German weapons programs, and for the example of how Richard Kuhn was unaware of Gerhard Schrader's work, see p. 2584.

An 18 June 1945 Allied report described some of the security measures that were employed in the secret weapons programs [CIOS ER 112]:

> [...] Security Precautions Surrounding Secret Weapons: Plans, designs and other important papers concerning top secret weapons were distributed in four parts by relay teams. Each part was wholly unintelligible without the other three parts. To keep location of plants secret the relay system was used. One courier would take 1/4 of a plan about 100 km. and turn it over to another courier, whose destination was unknown to the first, just as point of origin of the first courier was unknown to the second. This procedure was repeated frequently so that the final courier alone knew the destination of plan.

Another important reason that security in the chemical weapons program was so effective was that most of the labor involved in production was performed by concentration camp inmates, and those inmates either died in the course of their work or were systematically tracked down and killed afterward [Tucker 2006, pp. 70–71]:

> On January 24 [1945], shortly before the first vanguard of Soviet troops reached the Oder River, the Dyhernfurth director, Dr. Albert Palm, gave the order to evacuate all staff members and the 3,000 inmates of the two satellite labor camps. [...]
>
> By the time the forced laborers reached the Gross-Rosen concentration camp, two thirds of the original 3,000 had died or been killed. On February 11, the SS transferred the survivors from Gross-Rosen to Mauthausen concentration camp. [...] Because the Nazis wanted to eliminate all outside witnesses of nerve gas production at Dyhernfurth, the Gestapo tracked down the survivors at Mauthausen and murdered them. [...]

The same German organizations (Army Ordnance Office, SS, I.G. Farben, etc.) that were involved with the chemical weapons program were involved with the nuclear program. If those organizations could conduct a very large, very advanced, and very successful chemical weapons program from the 1930s until the very end of the war without Allied intelligence and the Alsos Mission discovering that, they could have done the same for a nuclear weapons program.

In fact, existing sources of information on the German nuclear weapons program, such as Ivan Ilyichev (see pp. 4481–4485) and Werner Grothmann (see p. 3400), depicted the severe secrecy and security measures of that program. More specifically, they described the nuclear program as having employed both the same extreme compartmentalization of knowledge and the same systematic use and killing of large numbers of concentration camp inmates as are known to have been employed in the chemical weapons program.

In the years after the war, any scientists, military personnel, or political leaders who did have real insight into the nuclear weapons program would have been strongly motivated to permanently conceal their involvement for fear of being tried for war crimes by the Allies or secretly killed by surviving members of the SS. If any of those personnel went to work for Allied governments and revealed any of the information to them, they would have been equally sworn to secrecy by their new employers.

C. Timeline of the German Nuclear Program

The timeline of the wartime German nuclear program may be analyzed by comparing it to the timelines for the early U.S. and Soviet nuclear weapons development programs.

Figure D.1023 shows the timeline of the early U.S. nuclear weapons program, whose history is well documented.[24] The U.S. program was prompted by the famous 2 August 1939 letter from Albert Einstein and Leo Szilard to Franklin Roosevelt, but up until the end of 1941, the program accomplished remarkably little other than some relatively inexpensive academic experiments and some paper feasibility reports written by a succession of different study commissions. The 7 December 1941 Japanese attack on Pearl Harbor was the critical catalyzing event that brought the United States into the war and persuaded it to pursue a large and urgent nuclear weapons program from approximately the beginning of 1942 onward. The features most closely associated with the memory of the Manhattan Project generally happened very late in the war. The Los Alamos laboratory began operating in April 1943, just two years before the end of the war in Europe, and did not begin truly serious work on the implosion bomb design until July 1944, only 10 months before the end of the war in Europe. Sizeable quantities of uranium-235 and plutonium-239 were not available until the summer of 1945, when they were largely consumed by the 16 July Gadget plutonium implosion bomb test in New Mexico, the Little Boy gun-type uranium bomb dropped on Hiroshima on 6 August, and the Fat Man plutonium implosion bomb dropped on Nagasaki on 9 August.

Similarly, Fig. D.1024 shows the timeline of the early Soviet nuclear weapons program, whose history was shrouded in mystery for many decades but is now relatively well documented.[25] Although the Soviet government and its scientists had been interested in the possibility of nuclear weapons for several years, they were not in any position to pursue a serious program until 1945, when the war ended and they swept up as many scientists, materials, and information as possible from the former German nuclear program. Klaus Fuchs, Ted Hall, and other spies in the U.S. program also gave the Soviet government extremely detailed designs for the U.S. nuclear bombs, uranium enrichment plants, and plutonium production plants. According to the published histories, however, it was the 6 and 9 August 1945 U.S. nuclear attacks on Japan that served as the critical catalyzing event that persuaded Joseph Stalin to give his own nuclear program the greatest possible priority, funding, and urgency. The first Soviet fission bomb (RDS-1 or Joe-1), a direct copy of the U.S. Gadget/Fat Man plutonium implosion bomb, was successfully tested on 29 August 1949, and two more refined bombs (RDS-2 and RDS-3, or Joe-2 and Joe-3) were tested on 24 September and 18 October 1951. As with the U.S. program, significant quantities of uranium-235 and plutonium-239 were not available until very late in the Soviet program.

Figure D.1024: Timeline of the early Soviet nuclear weapons program.

The timelines of the U.S. and Soviet programs are remarkably similar, given that they happened at different times, in very different countries, and with different resources:

- The time from the critical catalyzing event to the first atomic bomb detonation was approximately 43.3 months for the U.S. program (7 December 1941 to 16 July 1945), and approximately 48.7 months for the Soviet program (6 and 9 August 1945 to 29 August 1949). If the United States benefitted significantly from information, materials, or personnel from the German program as some of the evidence in Section D.14 suggests, an unaided U.S. program would have required several more months and thus would have been even closer to the duration of the Soviet program.

- A fission reactor is a necessary step for a Pu-239 bomb program (unless a country resorts to accelerator-driven electronuclear breeding on a large scale); a fission reactor is optional (though potentially helpful) for a U-235 bomb program. The United States demonstrated its first fission reactor (Chicago Pile 1, or CP-1) on 2 December 1942, approximately 12 months after its critical catalyzing event. The Soviet Union demonstrated its first fission reactor (F-1) on 25 December 1946, approximately 16.5 months after its critical catalyzing event, or approximately 12 months after it was able to begin setting up its spoils from Germany (including at least 300 tons of German-produced uranium oxide, which fueled both F-1 and the larger second Soviet fission reactor).

- For both the U.S. and Soviet programs, significant quantities of Pu-239 were not available until just weeks prior to the first atomic bomb detonation, with a period of several years being required to build and test the infrastructure and equipment necessary to breed and purify Pu-239, and several months required to actually produce it. (An electronuclear breeding program would also require several years to build and operate enough particle accelerators to produce a sufficient quantity of Pu-239 or U-233 for a bomb.)

- For both the U.S. and Soviet programs, significant quantities of highly enriched U-235 were not available until just weeks or months prior to the first uranium bomb detonation, with a period of several years being required to build and test the infrastructure and equipment necessary to do high-level enrichment, and several months required to actually do the enrichment.

By comparison to the U.S. and Soviet programs, the timeline of the wartime German nuclear program is much less clear and much more controversial. Figure D.1025 shows the “minimalist” scenario for the German timeline, based on the widely held conventional historical view that relatively little of significance was accomplished during the program [Bernstein 2001; Cassidy 1992, 2009; Frank 1993; Goudsmit 1945, Goudsmit 1947; Groves 1962; Hentschel and Hentschel 1996; Hoffmann 2023; Irving 1967; Pash 1969; Powers 1993; Rose 1998; Schaaf 2001; von Schirach 2015; Walker 1989, 1995, 2020, 2024a, 2024b]. The minimalist scenario may or may not be the correct view of the actual historical events, but the basic details claimed for the program and its timeline have remained relatively fixed across a wide range of minimalist authors for 75+ years; thus at least in that sense, one may regard the minimalist scenario as fairly well documented and relatively well understood.

Figure D.1025: Timeline of the German nuclear weapons program, based on the minimalist scenario.

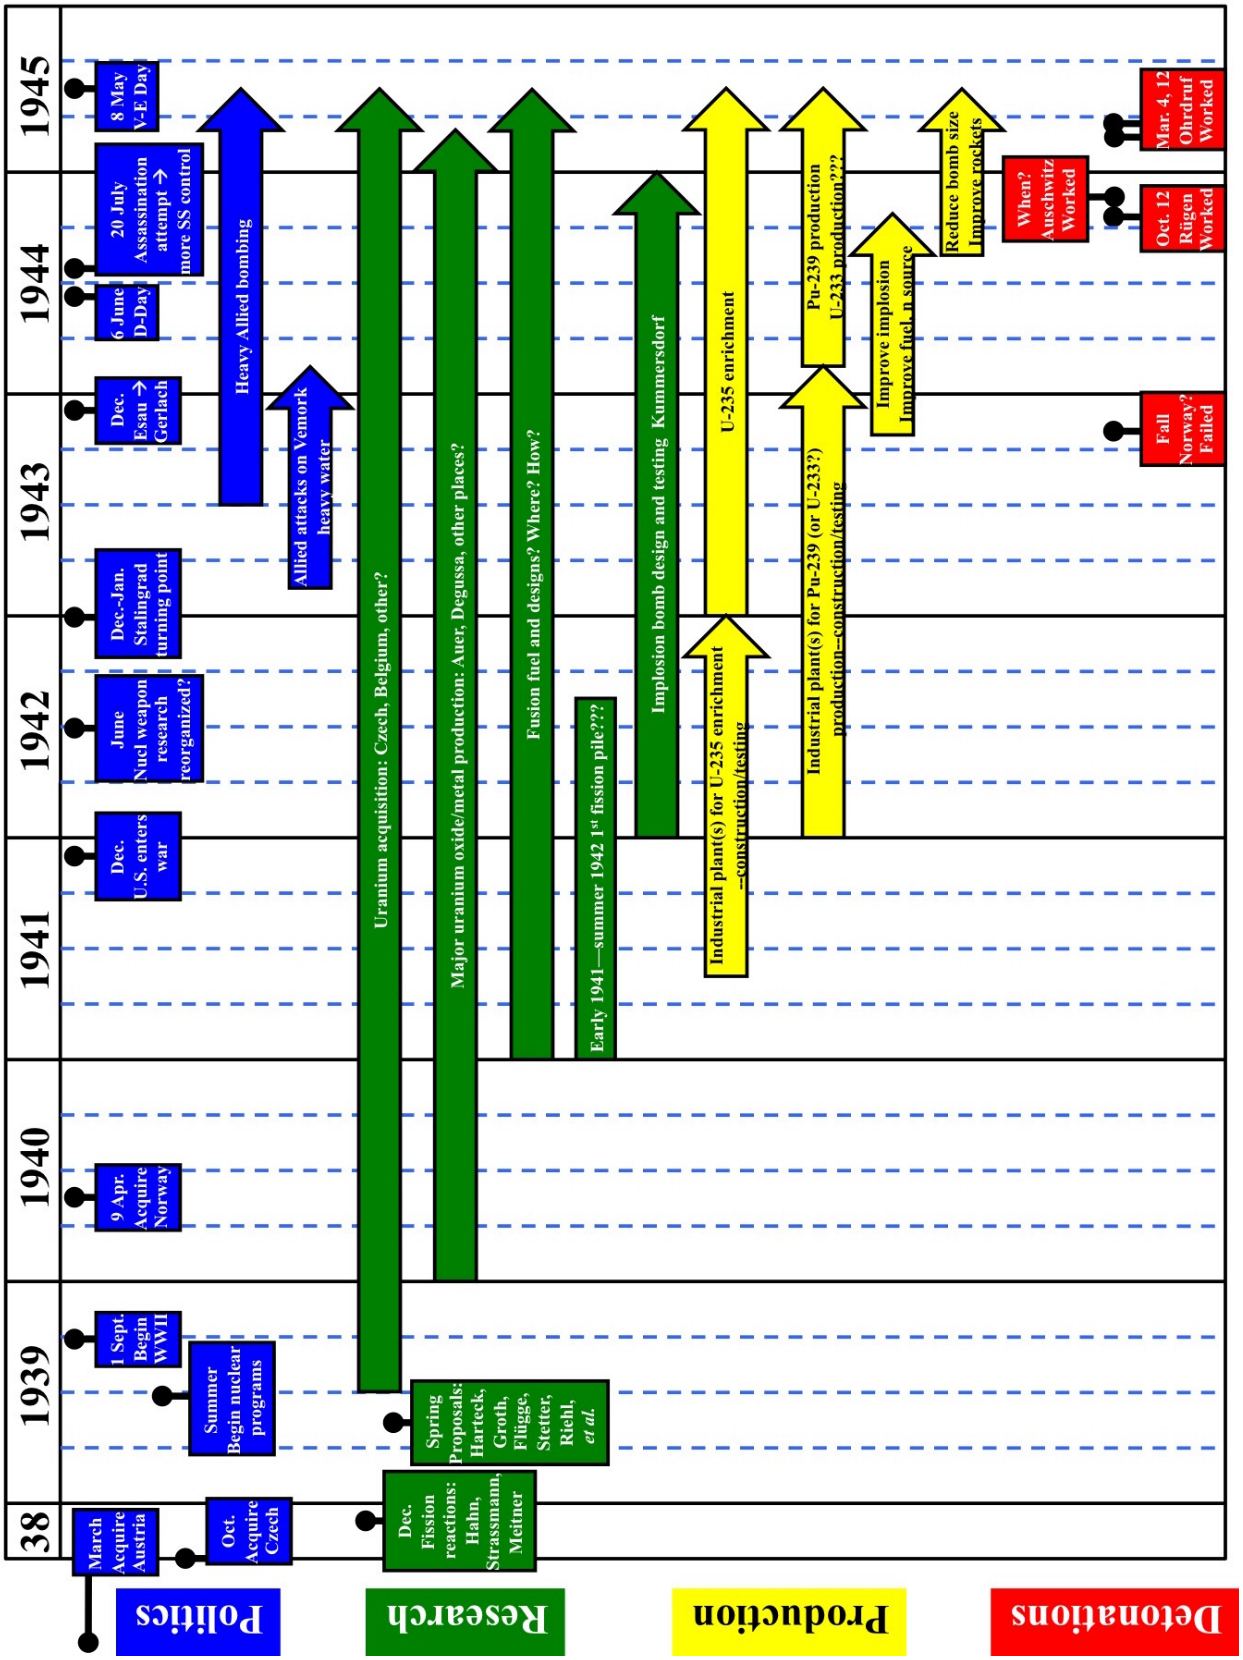

Figure D.1026: Timeline of the German nuclear weapons program, based on the maximalist scenario.

In stark contrast to the minimalist scenario, Fig. D.1026 shows the "maximalist" scenario for the German timeline, based largely on 2000–2002 interviews with Heinrich Himmler's chief adjutant Werner Grothmann, the source that both (a) made specific claims for the greatest amount of progress in the German nuclear program and (b) still had a plausible case for being historically well-informed. From p. 4436, the most profound claims made by Grothmann are that there was a failed nuclear weapons test in autumn 1943 in the North Sea, two successful tests in autumn 1944 (which could agree with the tests on the Baltic coast and in Poland that were reported by several other sources), and a test in March 1945 in Thuringia (or two tests, as reported by Ivan Ilyichev and Cläre Werner), and that Germany developed uranium bombs, plutonium bombs, and bombs apparently incorporating significant fusion reactions. As shown by the other documents quoted in this appendix, there is evidence from other sources that appears to support each of Grothmann's major claims. As was stated for the minimalist scenario, this maximalist scenario may or may not be the correct view of the actual historical events, but it is worthy of serious consideration and scrutiny.

The defining characteristics of the maximalist scenario are its end points—the development of uranium, plutonium, and fusion bombs, and the staging of at least five nuclear weapons tests before the end of the war. Unfortunately the key sources for the maximalist scenario give relatively little information about the program, intermediate steps, and timeline that led to those end points. Nonetheless, by using known historical events and parallels to the early U.S. and Soviet nuclear programs, one may "fill in the gaps" in the maximalist scenario and make plausible conjectures about the steps that would have been necessary for the German nuclear program to arrive at those end points:

1. For the very large and very urgent U.S. and Soviet nuclear programs, the time from the critical catalyzing event to the first atomic bomb detonation was roughly four years. Postwar Allied military accounts stated that the intense Allied bombing of Germany during the last two years of the war delayed Germany's development of new rockets, jets, and other strategic military technologies by at least six months. Coupled with materials shortages due to the Allied bombing and blockades, the total delay may have been more like 12 months. Thus one might expect that the German nuclear program would require roughly five years from its critical catalyzing event to its first successful bomb test. If the alleged 12 October 1944 atomic bomb test on the Baltic coast was indeed real and was indeed Germany's first successful test, one would look for a critical catalyzing event approximately five years before that, and the September 1939 declarations of war appear to be the most obvious choice. Corollaries to this line of reasoning are that:

    (a) If the German nuclear program began around September 1939 and truly did conduct a successful nuclear bomb test within five years (including the delays for Allied bombing and blockades), then during that five-year period, the German nuclear program would probably have had a size and urgency comparable to the U.S. and Soviet programs.

    (b) If the German nuclear program had been significantly smaller or less urgent than the wartime U.S. and postwar Soviet nuclear programs, it seems unlikely that it could have succeeded before the end of the war.

2. If Germany developed Pu-239 (or U-233) bombs, it would have needed to construct and operate one or more fission reactors (or a large electronuclear breeding program, which would have required a comparable amount of time). For the U.S. and Soviet programs, processed uranium oxide was already available prior to the critical catalyzing event (from earlier work for the U.S. program, and from German work for the Soviet program), and the first fission reactor became operational 12–16 months after the catalyzing event. A second, alternative criterion is that for both the U.S. and Soviet programs, the first fission reactor became operational approximately 32 months before a functional plutonium implosion bomb, due to the time required to transition from a small laboratory reactor to a large industrial reactor, create and optimize the plutonium extraction process, and actually produce enough plutonium for a bomb. Using the first criterion, if Germany had a critical catalyzing event in September 1939 and began processing uranium ore into uranium oxide at the beginning of 1940, one would expect the first fission reactor to become operational no earlier than the beginning of 1941. Using the second criterion, if Germany had a functional plutonium bomb ready no later than April 1945, one would expect the first fission reactor to have become operational no later than August 1942. How much evidence is there that Germany had one or more functional fission reactors? Is there any evidence that Germany's first fission reactor became operational sometime between early 1941 and summer 1942? If that actually happened, Germany would have demonstrated the world's first fission reactor sometime before the U.S. CP-1 became operational. Corollaries to this line of reasoning include:

    (a) If Germany did not have a functional fission reactor (or a very large electronuclear breeding program), it could not have had a serious plutonium bomb program.

    (b) If Germany had a functional fission reactor but it first became operational much later than August 1942 (or if the electronuclear breeding program became operational too late in the war), any plutonium bomb design would probably have still been waiting to receive a sufficient mass of Pu-239 when the war ended.

    (c) If Germany had a plutonium bomb program and operational fission reactors or electronuclear breeders, an industrial plant for extracting Pu-239 from spent uranium fuel (or U-233 from thorium) would have likely been adjacent to one or more of the fission reactors or electronuclear breeders.

3. It took the U.S. and Soviet programs at least 2.5 years to construct and test infrastructure and equipment to enrich U-235 to weapons-grade levels and to produce enough U-235 for their first uranium bombs; even before building that infrastructure, significant time was spent to research and develop the underlying scientific techniques. If Germany had enough enriched uranium to attempt a U-235 bomb test in late 1943, it most likely would have to have begun building industrial enrichment plants no later than early 1941, and to have been researching and developing enrichment techniques in laboratories before that. If Germany did not have enough enriched uranium for a bomb until March 1945, construction of industrial enrichment plants could have begun as late as around September 1942.

    (a) What evidence is there for large-scale, early, and/or high-level uranium enrichment work in Germany?

    (b) What possible industrial uranium enrichment plants began construction in 1941–1942?

4. If Germany conducted a failed bomb test in autumn 1943 but successful tests in autumn 1944, much of the work during the intervening period would have been focused on solving the problem(s) that led to the failure. (The failed autumn 1943 test may also account for the replacement of Abraham Esau by Walther Gerlach as "Plenipotentiary of Nuclear Physics" in late 1943.) The most obvious improvements would be:
    (a) Improving the implosion system to better synchronize and improve the symmetry of the implosion, and/or to increase the degree of compression of the fission fuel during the implosion.
    (b) Increasing the mass and/or purity of the fission fuel.
    (c) Improving the neutron output and/or reliability of the neutron source used to initiate a chain reaction when the fission fuel is maximally compressed.
5. If Germany conducted one or more successful bomb tests in autumn 1944 but still felt the need to conduct more bomb tests in March 1945, the simplest explanation is that the autumn 1944 bomb was so large and heavy (like the U.S. bombs) that it was much better suited to being dropped from an aircraft than carried by a rocket. Most German aircraft had become vulnerable to Allied attacks, whereas rockets could not be intercepted. Thus much of the work between autumn 1944 and March 1945 would have been focused on:
    (a) Reducing the mass and diameter of the bomb.
    (b) Increasing the payload capacity, range, and accuracy of rockets to carry the bomb.

It is important to reiterate that both the minimalist and maximalist scenarios considered here are hypothetical constructs that may be useful in thinking about this murky area of history. Each of these scenarios may or may not actually be true history; certainly both scenarios cannot be simultaneously correct. What were the actual historical events of the real German wartime nuclear program (Fig. D.1027)? Were they some suitably refined version of the minimalist scenario, some refined version of the maximalist scenario, or something intermediate between those two scenarios?

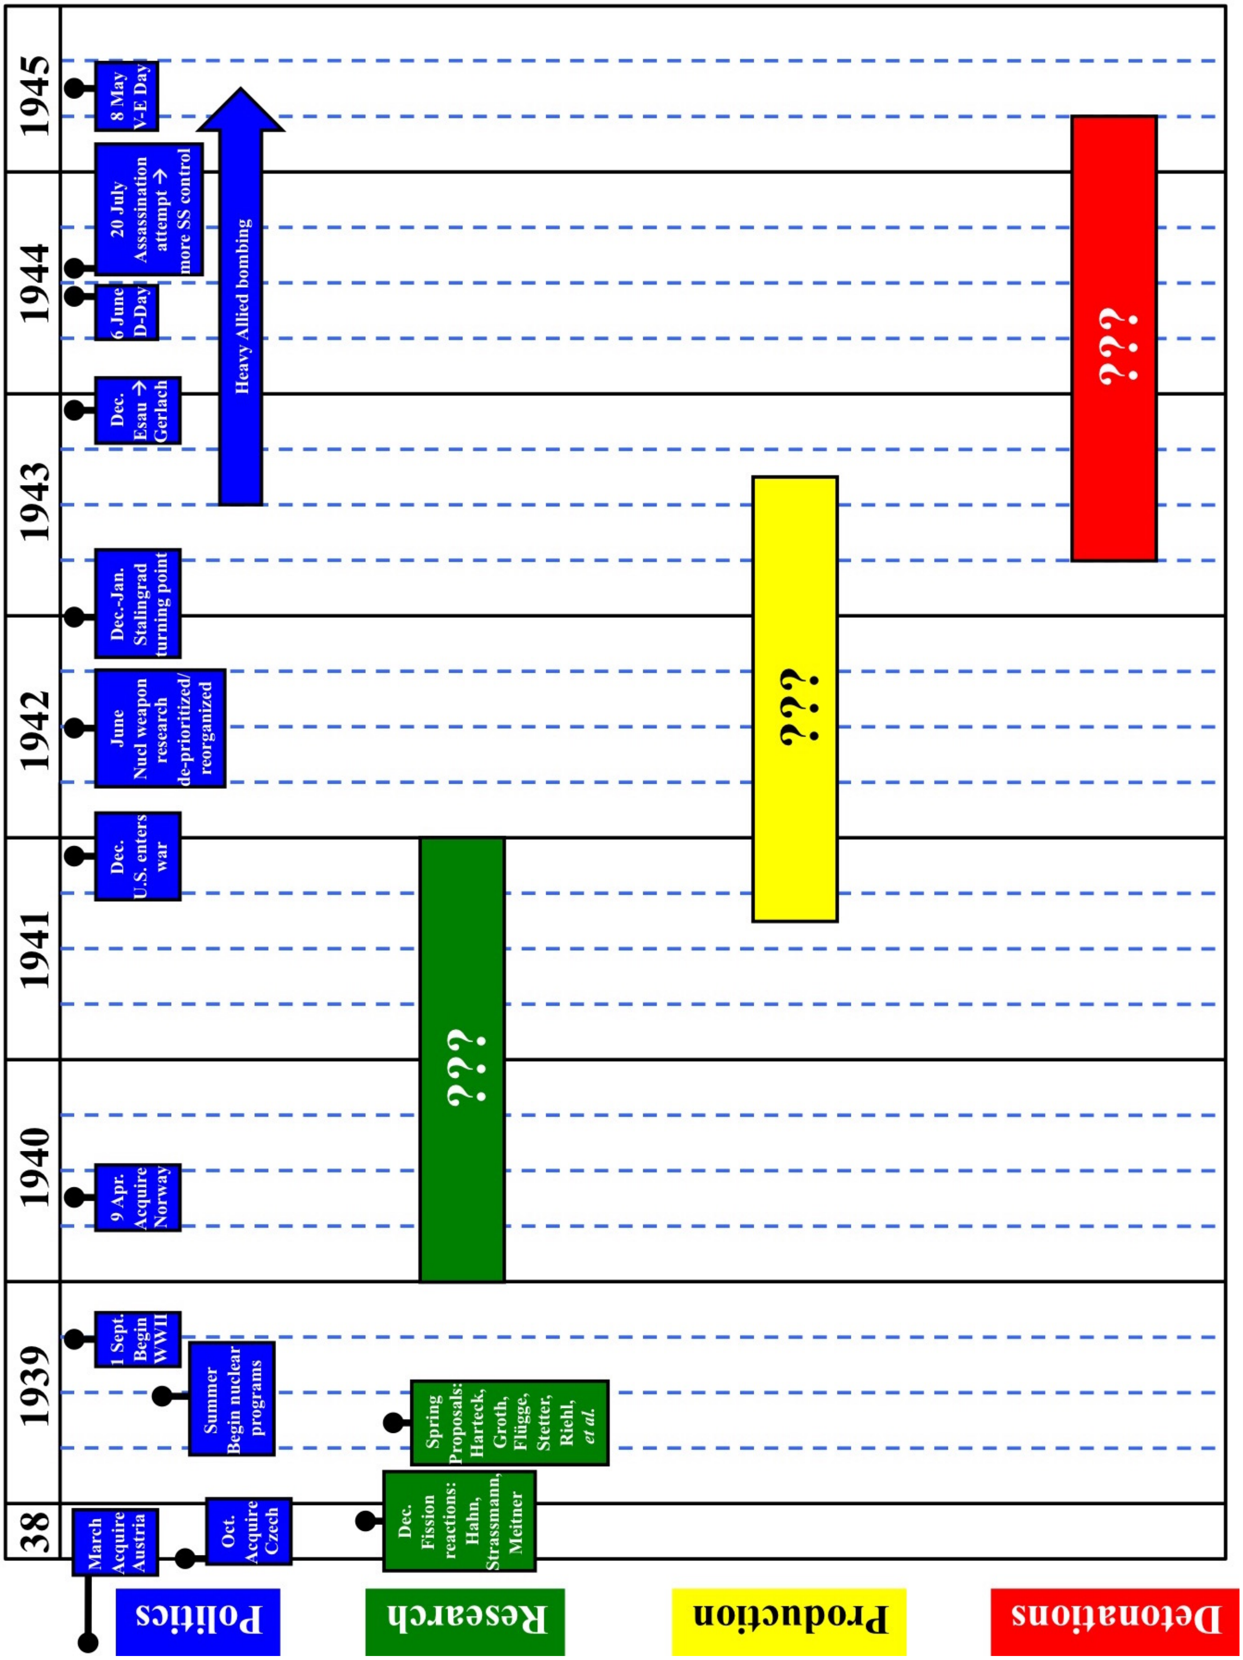

Figure D.1027: Timeline of the German nuclear weapons program, based on actual historical events.

D. Organization of the German Nuclear Program

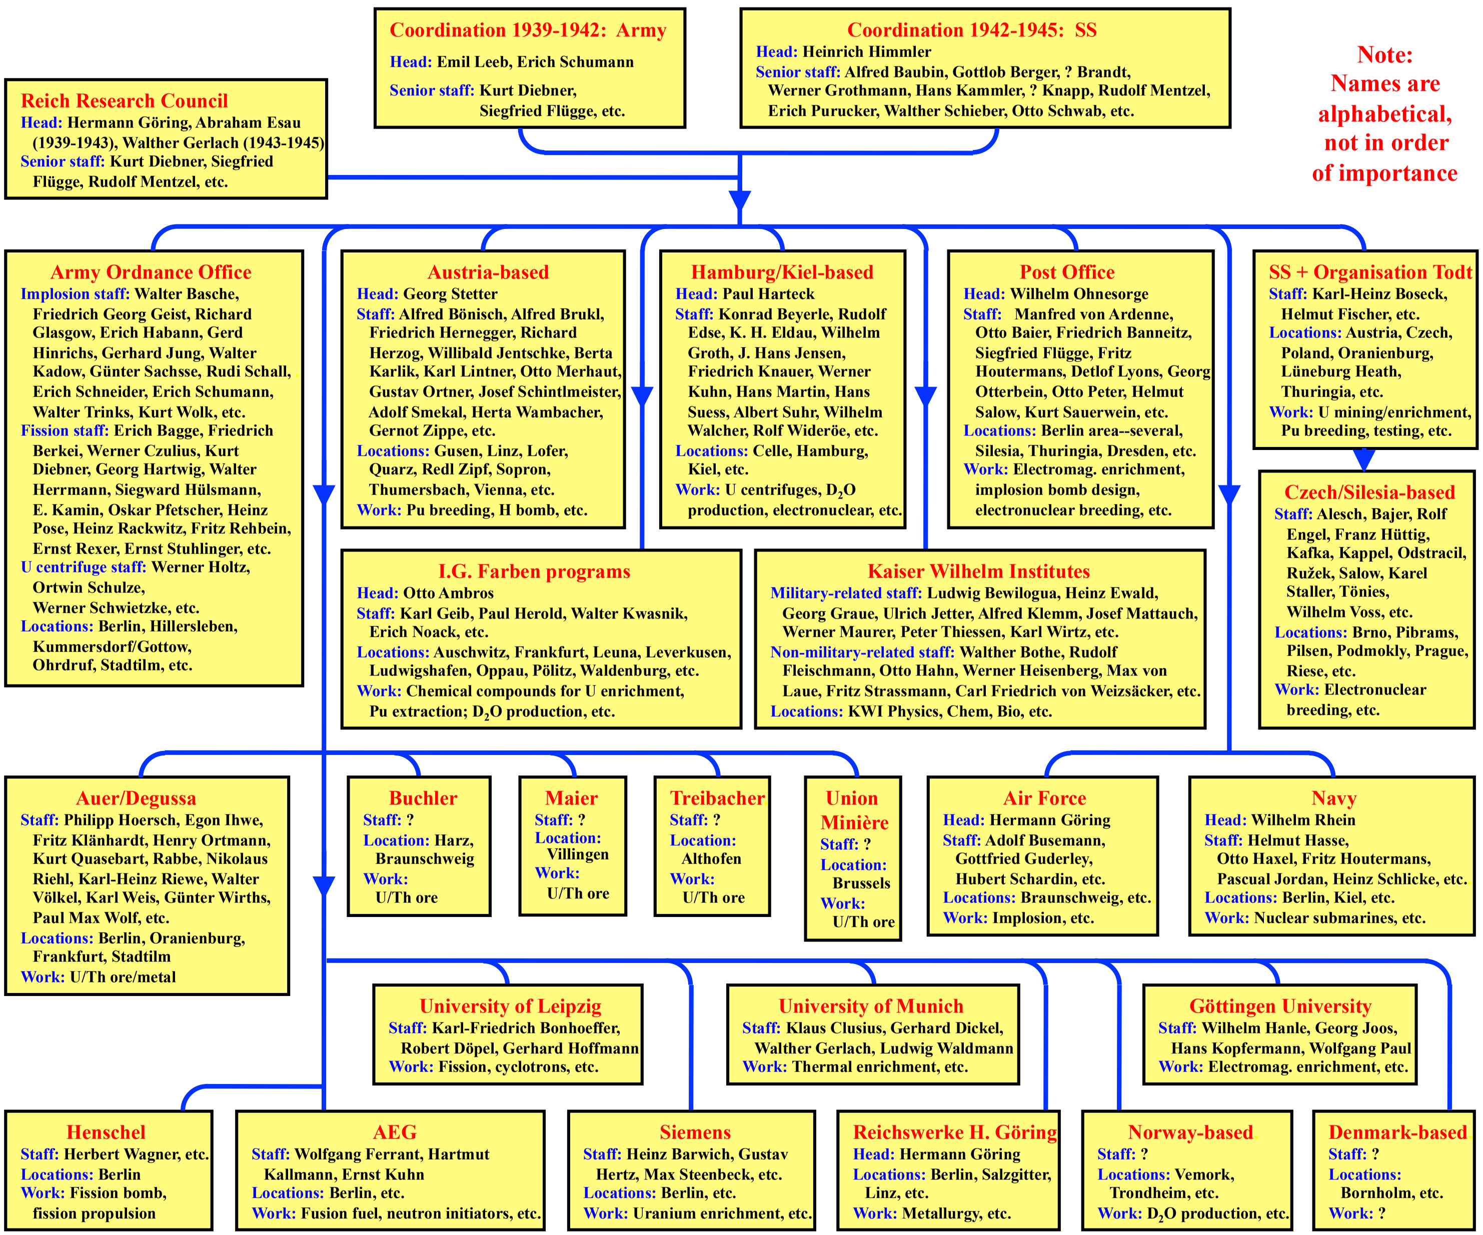
The German nuclear program was very large and highly compartmentalized. Because so much of the relevant information was destroyed by the Germans at the end of the war or captured and classified by different Allied countries after the war, it is quite difficult for modern historians to accurately reconstruct the organizational details of the program.

Page 5109 presents a tentative organizational chart of the German nuclear program, based on information such as that from pp. 1565–1629 and 3402–3403.

In a nutshell, the overall management of the program was handled by the Army in the earlier years of the war and by the SS in the later years of the war, both with some input from the Reich Research Council.

Those managing agencies oversaw work that was spread over at least a couple dozen different organizations (military groups, other government-run laboratories, companies, and universities), many of which had multiple physical locations.

There was considerable redundancy among those organizations in their work, which may seem inefficient to the modern observer but appears to have served well to make the German nuclear program much less vulnerable to Allied intelligence and bombing.



Note: Names are alphabetical, not in order of importance
Reich Research Council
Head: Hermann Göring, Abraham Esau (1939-1943), Walther Gerlach (1943-1945)
Senior staff: Kurt Diebner, Siegfried Flügge, Rudolf Mentzel, etc.
Coordination 1939-1942: Army
Head: Emil Leeb, Erich Schumann
Senior staff: Kurt Diebner, Siegfried Flügge, etc.
Coordination 1942-1945: SS
Head: Heinrich Himmler
Senior staff: Alfred Baubin, Gottlob Berger, ? Brandt, Werner Grothmann, Hans Kammler, ? Knapp, Rudolf Mentzel, Erich Purucker, Walther Schieber, Otto Schwab, etc.
Army Ordnance Office
Implosion staff: Walter Basche, Friedrich Georg Geist, Richard Glasgow, Erich Habann, Gerd Hinrichs, Gerhard Jung, Walter Kadow, Günter Sachsse, Rudi Schall, Erich Schneider, Erich Schumann, Walter Trinks, Kurt Wolk, etc.
Fission staff: Erich Bagge, Friedrich Berkei, Werner Czulius, Kurt Diebner, Georg Hartwig, Walter Herrmann, Siegward Hülsmann, E. Kamin, Oskar Pfetscher, Heinz Pose, Heinz Rackwitz, Fritz Rehbein, Ernst Rexer, Ernst Stuhlinger, etc.
U centrifuge staff: Werner Holtz, Ortwin Schulze, Werner Schwietzke, etc.
Locations: Berlin, Hillersleben, Kummersdorf/Gottow, Ohrdruf, Stadtilm, etc.
Austria-based
Head: Georg Stetter
Staff: Alfred Bönisch, Alfred Brukl, Friedrich Hernegger, Richard Herzog, Willibald Jentschke, Berta Karlik, Karl Lintner, Otto Merhaut, Gustav Ortner, Josef Schintlmeister, Adolf Smekal, Herta Wambacher, Gernot Zippe, etc.
Locations: Gusen, Linz, Lofer, Quarz, Redl Zipf, Sopron, Thumersbach, Vienna, etc.
Work: Pu breeding, H bomb, etc.
Hamburg/Kiel-based
Head: Paul Harteck
Staff: Konrad Beyerle, Rudolf Edse, K. H. Eldau, Wilhelm Groth, J. Hans Jensen, Friedrich Knauer, Werner Kuhn, Hans Martin, Hans Suess, Albert Suhr, Wilhelm Walcher, Rolf Wideröe, etc.
Locations: Celle, Hamburg, Kiel, etc.
Work: U centrifuges, D_2O production, electronuclear, etc.
Post Office
Head: Wilhelm Ohnesorge
Staff: Manfred von Ardenne, Otto Baier, Friedrich Banneitz, Siegfried Flügge, Fritz Houtermans, Detlof Lyons, Georg Otterbein, Otto Peter, Helmut Salow, Kurt Sauerwein, etc.
Locations: Berlin area--several, Silesia, Thuringia, Dresden, etc.
Work: Electromag. enrichment, implosion bomb design, electronuclear breeding, etc.
SS + Organisation Todt
Staff: Karl-Heinz Boseck, Helmut Fischer, etc.
Locations: Austria, Czech, Poland, Oranienburg, Lüneburg Heath, Thuringia, etc.
Work: U mining/enrichment, Pu breeding, testing, etc.
Czech/Silesia-based
Staff: Alesch, Bajer, Rolf Engel, Franz Hüttig, Kafka, Kappel, Odstracil, Ružek, Salow, Karel Staller, Tönies, Wilhelm Voss, etc.
Locations: Brno, Pibrams, Pilsen, Podmokly, Prague, Riese, etc.
Work: Electronuclear breeding, etc.
I.G. Farben programs
Head: Otto Ambros
Staff: Karl Geib, Paul Herold, Walter Kwasnik, Erich Noack, etc.
Locations: Auschwitz, Frankfurt, Leuna, Leverkusen, Ludwigshafen, Oppau, Pölitz, Waldenburg, etc.
Work: Chemical compounds for U enrichment, Pu extraction; D_2O production, etc.
Kaiser Wilhelm Institutes
Military-related staff: Ludwig Bewilogua, Heinz Ewald, Georg Graue, Ulrich Jetter, Alfred Klemm, Josef Mattauch, Werner Maurer, Peter Thiessen, Karl Wirtz, etc.
Non-military-related staff: Walther Bothe, Rudolf Fleischmann, Otto Hahn, Werner Heisenberg, Max von Laue, Fritz Strassmann, Carl Friedrich von Weizsäcker, etc.
Locations: KWI Physics, Chem, Bio, etc.
Auer/Degussa
Staff: Philipp Hoersch, Egon Ihwe, Fritz Klänhardt, Henry Ortmann, Kurt Quasebart, Rabbe, Nikolaus Riehl, Karl-Heinz Riewe, Walter Völkel, Karl Weis, Günter Wirths, Paul Max Wolf, etc.
Locations: Berlin, Oranienburg, Frankfurt, Stadtilm
Work: U/Th ore/metal
Buchler
Staff: ?
Location: Harz, Braunschweig
Work: U/Th ore
Maier
Staff: ?
Location: Villingen
Work: U/Th ore
Treibacher
Staff: ?
Location: Althofen
Work: U/Th ore
Union Minière
Staff: ?
Location: Brussels
Work: U/Th ore
Air Force
Head: Hermann Göring
Staff: Adolf Busemann, Gottfried Guderley, Hubert Schardin, etc.
Locations: Braunschweig, etc.
Work: Implosion, etc.
Navy
Head: Wilhelm Rhein
Staff: Helmut Hasse, Otto Haxel, Fritz Houtermans, Pascual Jordan, Heinz Schlicke, etc.
Locations: Berlin, Kiel, etc.
Work: Nuclear submarines, etc.
University of Leipzig
Staff: Karl-Friedrich Bonhoeffer, Robert Döpel, Gerhard Hoffmann
Work: Fission, cyclotrons, etc.
University of Munich
Staff: Klaus Clusius, Gerhard Dickel, Walther Gerlach, Ludwig Waldmann
Work: Thermal enrichment, etc.
Göttingen University
Staff: Wilhelm Hanle, Georg Joos, Hans Kopfermann, Wolfgang Paul
Work: Electromag. enrichment, etc.
Henschel
Staff: Herbert Wagner, etc.
Locations: Berlin
Work: Fission bomb, fission propulsion
AEG
Staff: Wolfgang Ferrant, Hartmut Kallmann, Ernst Kuhn
Locations: Berlin, etc.
Work: Fusion fuel, neutron initiators, etc.
Siemens
Staff: Heinz Barwich, Gustav Hertz, Max Steenbeck, etc.
Locations: Berlin, etc.
Work: Uranium enrichment, etc.
Reichswerke H. Göring
Head: Hermann Göring
Locations: Berlin, Salzgitter, Linz, etc.
Work: Metallurgy, etc.
Norway-based
Staff: ?
Locations: Vemork, Trondheim, etc.
Work: D_2O production, etc.
Denmark-based
Staff: ?
Locations: Bornholm, etc.
Work: ?

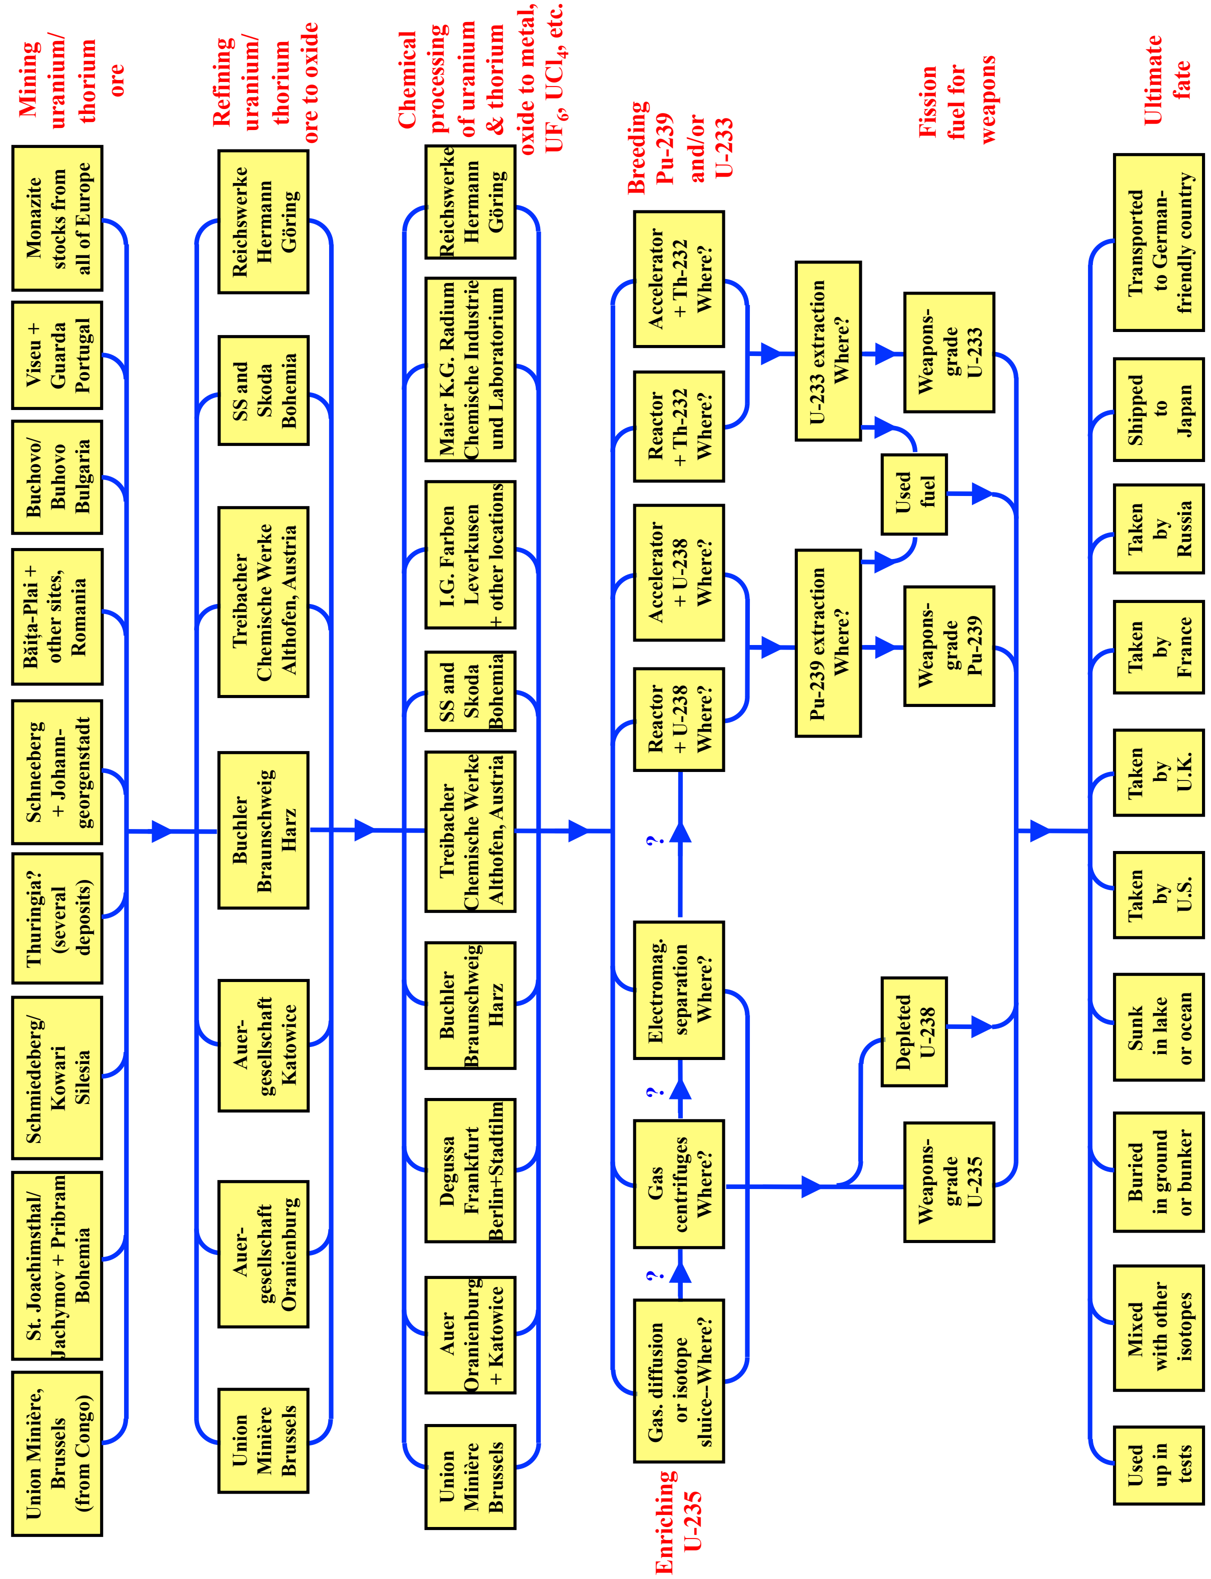
Figure D.1028: Very tentative organizational chart of the German nuclear program.

In order to understand the science of the German nuclear program, it is helpful to look at the program from a different viewpoint other than organizational approach of Fig. D.1028. In the film *All the President's Men*, the advice to "follow the money" was the key to investigating Watergate. Similarly, the key to investigating the wartime German nuclear program should be to "follow the actinides." Actinides are fissionable heavy elements, chiefly thorium, uranium, and plutonium.

Unfortunately, many vital details about the flow of actinides in the Third Reich are presently unknown.

As a guide in understanding the currently available information and in seeking more extensive information, p. 5111 presents a tentative and simplified overview of the actinide pathways and possibilities.

Much more research is needed to investigate and to clarify whether and how these pathways were actually implemented during the war.



Mining uranium/ thorium ore
Union Minière, Brussels (from Congo)
St. Joachimsthal/ Jachymov + Pribram Bohemia
Schmiedeberg/ Kowari Silesia
Thuringia? (several deposits)
Schneeberg + Johann- georgenstadt
Băița-Plai + other sites, Romania
Buchovo/ Buhovo Bulgaria
Viseu + Guarda Portugal
Monazite stocks from all of Europe
Refining uranium/ thorium ore to oxide
Union Minière Brussels
Auer- gesellschaft Oranienburg
Auer- gesellschaft Katowice
Buchler Braunschweig Harz
Treibacher Chemische Werke Althofen, Austria
SS and Skoda Bohemia
Reichswerke Hermann Göring
Chemical processing of uranium & thorium oxide to metal, UF$_6$, UCl$_4$, etc.
Union Minière Brussels
Auer Oranienburg + Katowice
Degussa Frankfurt Berlin+Stadtilm
Buchler Braunschweig Harz
Treibacher Chemische Werke Althofen, Austria
SS and Skoda Bohemia
I.G. Farben Leverkusen + other locations

U-233 extraction Where?
Fission fuel for weapons
Weapons- grade U-235
Weapons- grade Pu-239
Weapons- grade U-233
Ultimate fate
Used up in tests
Mixed with other isotopes
Buried in ground or bunker
Sunk in lake or ocean
Taken by U.S.
Taken by U.K.
Taken by France
Taken by Russia
Shipped to Japan
Transported to German- friendly country

Figure D.1029: Known and extrapolated actinide (thorium, uranium, and plutonium) use in the German nuclear program.

During the war, Germany had access to large amounts of natural uranium and thorium ore by (see map on p. 3405):

- Acquiring at least 1200 tons, and according to some well-informed sources 3500 tons, of uranium compounds (originally mined in the Belgian Congo) from Union Minière in Brussels [e.g., pp. 3335, 3408–3414].
- Expanding uranium mining at St. Joachimsthal (Jachymov), Bohemia [e.g., pp. 3418–3429, 3445, 3469–3470, 4978–4984; Hayes 2004, pp. 132–133, 235, 243].
- Mining uranium at Příbram/Przibram/Pibrans, Bohemia [e.g, pp. 3424, 3470, 3751–3754].
- Mining uranium at Schmiedeberg, Silesia [e.g., pp. 3328, 3424, 3429, 3445, 3471].
- Possibly using any of several uranium deposits in Thuringia [e.g., pp. 3468–3469; Zeman and Karlsch 2008].
- Mining uranium at Schneeberg, Saxony [e.g., pp. 3416, 3424, 3426–3428, 3433–3437, 3445, 3456, 3468–3469, 3708, 4922; Zeman and Karlsch 2008].
- Mining uranium at Johanngeorgenstadt, Saxony [e.g., pp. 3416, 3424, 3426–3428, 3433–3437, 3456, 3468–3469, 3708, 4922; Zeman and Karlsch 2008].
- Mining uranium at Freiberg, Saxony [e.g., pp. 3424, 3426–3429, 3445, 3468–3469].
- Mining uranium at Durrnaul near Marienbad [e.g., p. 3424].
- Mining or planning to mine uranium at Mladkov/Wichstadt, Bohemia [e.g., p. 3425].
- Operating and receiving shipments from Bulgarian uranium mines such as a mine at Buchovo (or Buhovo, a suburb of Sofia), since 1938 [e.g., Hayes 2004, p. 235; https://ejatlas.org/conflict/life-after-the-uranium-mines-in-buhovo-bulgaria]. See also pp. 3446, 3470, 4588.
- Mining uranium at Băiţa-Plai and other sites in Romania [e.g., pp. 3449–3455, 3471].
- Acquiring uranium from mines at Viseu and Guarda, Portugal [e.g., p. 3445; Hayes 2004, p. 235].
- Procuring all available monazite thorium ore in occupied Europe [e.g., Irving 1967].
- Exploiting other possible sources—Spain, Scandinavia, etc.?

One 1946 U.S. intelligence report on Czech uranium mines noted, “The Germans put mining on a high priority and only mining was done throughout the 6 years occupation. The ore was delivered by special planes to Germany and Austria” (p. 3998). Another 1946 U.S. intelligence report added: “The Germans continued operations in this mine to the very last moment” (p. 4981).

Thus Germany began actively mining uranium in 1938 and continued until the end of the war. During that time, Germany had access to (1) the same quality and a comparable quantity of Congolese uranium that served the Manhattan Project well, (2) Central/Eastern European uranium mines that later served the Soviet nuclear program well, and (3) additional uranium mines too.

Germany processed uranium and thorium ore to uranium oxide and thorium oxide, and thence to uranium or thorium metal or to a variety of useful chemical compounds—uranium hexafluoride, uranium tetrachloride, uranium nitrate, etc.—at numerous locations including (see map on p. 3407):

- Union Minière in Brussels [e.g., pp. 3335, 3408–3414; Irving 1967, p. 65].
- Auer in Oranienburg, Katowice/Kattowitz, and other locations [e.g., pp. 3446, 3458, 3461–3463, 3465, 4980; Nagel 2016].
- Buchler in Braunschweig [e.g., pp. 3420, 3430–3431, 3458, 3460–3463, 3465, 4980].
- Treibacher Chemische Werke in Althofen, Austria [e.g., pp. 3420, 3432–3437, 3458, 3460, 4980; Gollmann 1994].
- Degussa in Frankfurt, Berlin, Stadtilm, and possibly other locations [e.g., pp. 3458, 3461–3465; Hayes 2004; Nagel 2016].
- Chemische Fabrik Grünau in Berlin [e.g., pp. 3438–3439, 3461–3463].
- I.G. Farben in Leverkusen and other locations [e.g., pp. 3488–3489, 3492–3493, 3678–3680, 3748–3750, 4440–4477; Mader 1965, pp. 193–202, 229-233].
- Krupp in Essen [e.g., pp. 3458, 3461–3463, 3465–3467].
- W. de Boer in Hamburg and Wittingen [e.g., pp. 3458, 3461–3463, 3465].
- Radium-Chemie AG in Frankfurt [e.g., pp. 3440–3441, 3458, 3465].
- W. Maier KG Radiumchemische Industrie und Laboratorium in Villingen-Schwenningen am Neckar and other locations [e.g., Oleynikov 2000].
- Příbram/Przibram/Pibrans, Bohemia [e.g., pp. 3423, 3751–3754].
- Facilities in Dresden [e.g., pp. 3423, 3426].
- Reichswerke Hermann Göring in Linz and other locations [e.g., pp. 3877–3880].
- Possibly other facilities.

At the end of the war, Allied countries removed over 2800 tons of uranium and thorium compounds from former German-controlled territory (p. 3456). In addition, in 1974, Alwin Urff, deputy technical plant manager of the Asse nuclear disposal site in Germany, stated: “When we began storage in 1967, our company first sank radioactive waste from the last war, that uranium waste which arose in the preparation of the German atomic bomb” (p. 3472).

German scientists developed and demonstrated methods of enriching uranium-235 from natural uranium:

- Konrad Beyerle, Wilhelm Groth, Werner Holtz, Werner Schwietzke, and many others worked in teams that developed gas centrifuges to enrich uranium-235. Centrifugation proved so superior to the U.S. Manhattan Project's enrichment methods that the German gas centrifuge designs are now the worldwide standard for uranium enrichment (p. 3494).

- Manfred von Ardenne, Heinz Ewald, Wolfgang Paul, Wilhelm Walcher, and many others worked in teams that developed electromagnetic separators to enrich uranium-235. These electromagnetic separators were comparable to the Manhattan Project's calutrons (p. 3554).

- Erich Bagge invented and successfully demonstrated a unique uranium enrichment device called an isotope sluice, which combined some features of centrifuges, electromagnetic separators, and gaseous diffusion (p. 3651).

- Erika Cremer, Rudolf Fleischmann, Gustav Hertz, and others developed gaseous diffusion methods suitable for enriching uranium-235 that were comparable to the Manhattan Project's gaseous diffusion technology (p. 3618).

These enrichment methods are analyzed in Section D.15.2.

If Germany scaled up any of these proven uranium enrichment methods in order to produce nuclear weapons, it would presumably have distributed that production capability among a number of small underground locations for protection against Allied bombing. Archival documents mention dozens of highly suspicious sites that might have been used for that purpose and that still have not been properly investigated (p. 3670).

Two or more enrichment methods might have been used together, with one method enriching natural uranium to a level moderately enriched in uranium-235, then forwarding that material to another method to be enriched to a higher level.

Among the few currently available sources, there is some evidence that German scientists were working on breeding plutonium-239 or uranium-233:

- Ludwig Bewilogua, Kurt Diebner, Paul Harteck, Otto Haxel, and many others worked in teams trying to develop fission reactors suitable for breeding plutonium-239 from natural uranium-238 or uranium-233 from natural thorium-232. Two reactors were on the brink of criticality by the end of the war, and there is some evidence that other reactors may have actually become operational during the war (p. 3794).

- Walther Bothe, Walter Dällenbach, Max Steenbeck, Rolf Wideröe, and many others worked on particle-accelerator-driven electronuclear systems suitable for breeding plutonium-239 from natural uranium-238 or uranium-233 from natural thorium-232. There is some evidence that such systems may have been operational during the war (p. 3954).

These breeding methods are analyzed in Section D.15.3.

One or more enrichment methods might have also been used in conjunction with one or more breeding methods, providing uranium somewhat enriched in uranium-235 to a fission reactor or electronuclear breeder to make it easier to produce neutrons and thus easier to breed plutonium-239 from the remaining uranium-238.

Various subsets of the above processes could have produced any or all of these fission fuels for nuclear weapons:

- Uranium-235.
- Plutonium-239.
- Uranium-233.

If the Third Reich ever truly had significant quantities of any bomb-grade fission fuel, as well as the actinide waste products from enriching and/or breeding that fuel, they must have been disposed of in one or more of the following ways:

- Used up in test explosions.
- Smelted together with large enough quantities of natural uranium or other materials to render them effectively unusable.
- Buried in the ground or a bunker, sunk in a lake or ocean, or otherwise hidden so well that they were never found, or were found only after the Soviet nuclear program was already very far along.
- Captured by the United States.
- Captured by the United Kingdom.
- Captured by France.
- Captured by Russia (only small quantities and/or discovered years later[26]).
- Shipped to Japan.
- Sent to other sympathetic countries, such as Switzerland, Spain, Argentina, etc.

---

[26] While the postwar Soviet program benefited enormously from all of the German scientists, materials, equipment, and information it acquired, it still required four full years after the war to produce enough plutonium for one plutonium bomb test, RDS-1/Joe-1, and even longer to produce enough highly enriched uranium for its first uranium-235-based bomb test, RDS-2/Joe-2. Stalin was desperate to test a nuclear weapon as soon as he possibly could, in order to show the world that the United States was not the only nuclear superpower (p. 4533). Therefore, the timeline of the Soviet nuclear program appears to prove that as many spoils as the Soviets found in Germany and former German-occupied territories, useful quantities of plutonium-239, uranium-233, or highly enriched uranium-235 were not among them, or perhaps were only discovered after the Soviets had produced enough of their own fission fuel.

D.15.2 Enrichment Methods to Produce U-235

Uranium ore in most deposits typically consists of 0.1–2% uranium mixed with other elements. As the first step in processing, the uranium ore is milled or refined to at least 80% U_3O_8; this refined product is called yellowcake due to its color.

By mass, natural uranium contains approximately 0.72% ^{235}U, 99.275% ^{238}U, and just a trace amount (0.005%) of ^{234}U. Natural uranium can be used in fission reactors employing either heavy water or very pure graphite (not contaminated by neutron-absorbing boron) as a moderator to slow down the neutrons and facilitate the chain reaction. For use in reactors using light (ordinary) water as a moderator, the ^{235}U content of the fuel must be increased to 2–4%. For use in fast reactors or fission bombs, the ^{235}U content must be increased to $\sim$50–90% (the higher the better). The excess ^{238}U that is removed is called depleted uranium or tails; it used for other applications such as military ammunition and nuclear bomb casings, due to its very high density and other properties.

Preferentially accumulating one isotope versus another of the same element is called enrichment. As shown in Fig. D.1030, there are several different methods of enrichment:

A. Electromagnetic separation.

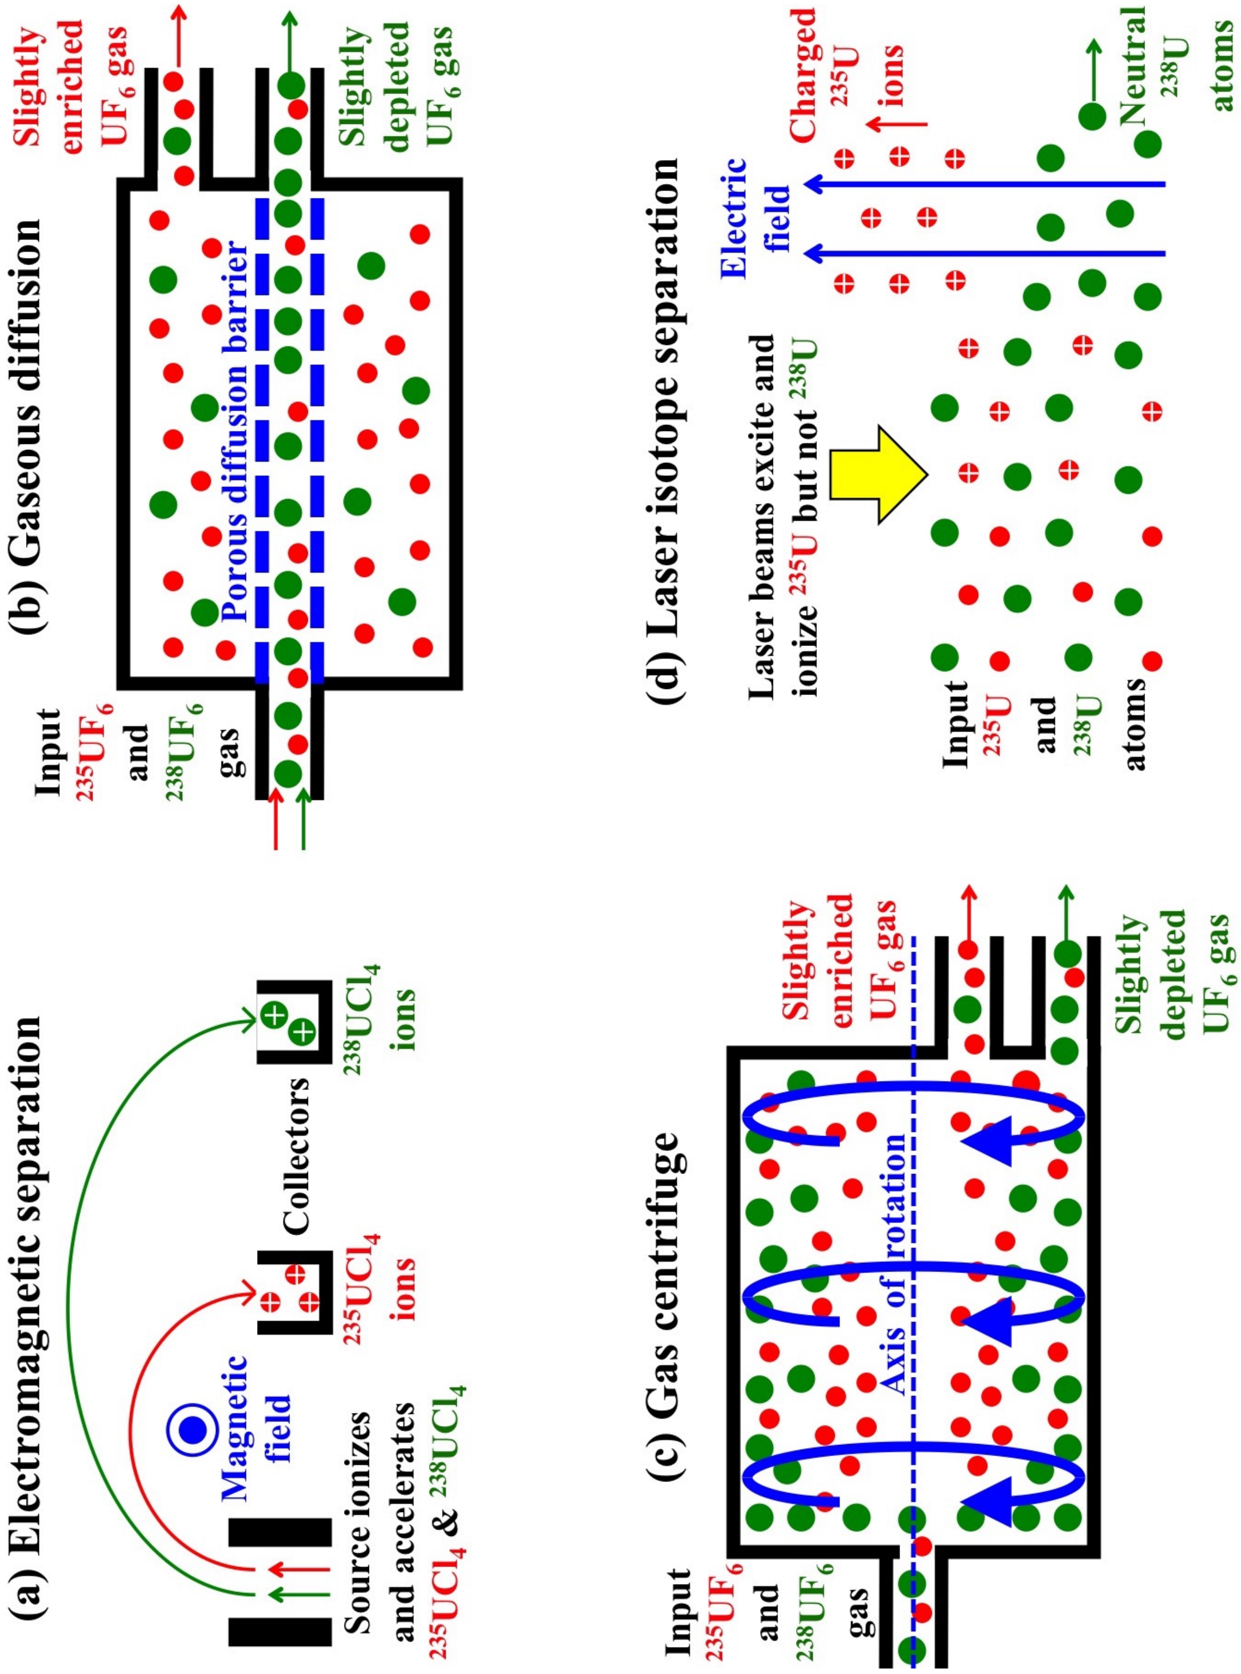
B. Gaseous diffusion.

C. Centrifugation.

D. Laser isotope separation.

The first two enrichment methods were used by the United States during World War II. Centrifugation is the main method used worldwide now. Laser isotope separation has been investigated for potential future use.

There is evidence that the wartime German nuclear program conducted research on all four of these enrichment methods. It is possible that any or all of the first three methods were used to produce enriched uranium for nuclear weapons, although most of the relevant information was either destroyed or may remain buried in classified archives. Much more work is needed to investigate the locations and methods of uranium enrichment that were used in the German nuclear program, as well as the amount and purity of the material that was produced.



(a) Electromagnetic separation
Magnetic field
Collectors
^{235}UCl$_4$ ions
^{238}UCl$_4$ ions
Source ionizes and accelerates ^{235}UCl$_4$ & ^{238}UCl$_4$
(b) Gaseous diffusion
Input ^{235}UF$_6$ and ^{238}UF$_6$ gas
Porous diffusion barrier
Slightly enriched UF$_6$ gas
Slightly depleted UF$_6$ gas
(c) Gas centrifuge
Input ^{235}UF$_6$ and ^{238}UF$_6$ gas
Axis of rotation
Slightly enriched UF$_6$ gas
Slightly depleted UF$_6$ gas
(d) Laser isotope separation
Laser beams excite and ionize ^{235}U but not ^{238}U
Input ^{235}U and ^{238}U atoms
Electric field
Charged ^{235}U ions
Neutral ^{238}U atoms

Figure D.1030: Uranium enrichment methods include (a) electromagnetic separation, (b) gaseous diffusion, (c) centrifugation, and (d) laser isotope separation.

A. Electromagnetic Separation

Mass spectrometers or circular particle accelerators can separate particles with different masses, as illustrated in Fig. D.1030(a). If uranium atoms are ionized and accelerated to a certain energy, an applied magnetic field can bend the paths of the uranium ions, with the trajectories of lower-mass ^{235}U ions having more curvature than those of higher-mass ^{238}U ions. This effect creates spatial separation between the two isotopes and thus can enrich the isotopes to very high purities. However, because of the very low particle densities and sophisticated equipment required, this enrichment approach tends to be very expensive for fission fuel. Nonetheless, all highly enriched ^{235}U produced in the United States during and soon after World War II was purified using electromagnetic separators called calutrons. Since the calutrons could produce highly enriched uranium but were limited by how much uranium they could process, they were most effective when they were fed with low-enriched uranium (from a separate gaseous diffusion plant) instead of natural uranium [Bruce Cameron Reed 2015a, 2019].

Manfred von Ardenne, Heinz Ewald, Wolfgang Paul, Wilhelm Walcher, and other German scientists developed methods for enriching uranium-235 via electromagnetic separation that were comparable to the U.S. calutrons (p. 3554). If Germany was secretly able to mass-produce and operate separators copied from those prototypes, it could have enriched enough uranium for one or more implosion bombs, especially test bombs with relatively small explosive yields such as those described by Werner Grothmann (p. 4436) and other witnesses. Indeed, according to Grothmann, the Reichspost built and operated a large uranium enrichment facility somewhere outside Berlin apparently based on von Ardenne's technology (p. 3494).

The physical size of an electromagnetic separator, and the distance by which it can separate uranium isotopes into two different streams, can be estimated from basic physics. The Lorentz force on an ion of mass m, velocity vector $\mathbf{v}$ (magnitude v), and singly ionized charge e in a magnetic field vector $\mathbf{B}$ (magnitude B) is

$$m\,\frac{d\mathbf{v}}{dt} \;=\; e\,\mathbf{v}\times\mathbf{B} \tag{D.17}$$

If the centripetal acceleration of the ion from Eq. (D.17) is the centripetal acceleration v^2/r_c required to go in a circular cyclotron orbit of radius r_c,

$$\left|\frac{dv}{dt}\right| \;=\; \frac{e\,v\,B}{m} \;=\; \frac{v^2}{r_c}\,, \tag{D.18}$$

then one can use the ion's kinetic energy $E = mv^2/2$ and mass A in atomic mass units to calculate the cyclotron radius:

$$r_c \;=\; \frac{\sqrt{2\,E\,m}}{eB} \;=\; 0.456\,\frac{\sqrt{E_{keV}}}{B_T}\,\sqrt{A}\;\text{ cm} \tag{D.19}$$

The diameter d_c of such a circular orbit is twice its radius:

$$d_c \;=\; 2\frac{\sqrt{2\,E\,m}}{eB} \;=\; 0.912\,\frac{\sqrt{E_{keV}}}{B_T}\,\sqrt{A}\;\text{ cm} \tag{D.20}$$

Two types of ions of masses A_1 and A_2 that begin at the same point with the same energy will be maximally separated by a distance Δd after half an orbit by the difference of their orbital diameters:

$$\Delta d_c \;=\; 2(r_{c1} - r_{c2}) \;=\; 0.912\,\frac{\sqrt{E_{keV}}}{B_T}\left(\sqrt{A_1} - \sqrt{A_2}\right) \;\;\text{cm} \tag{D.21}$$

The U.S. calutrons used 35 keV beams of singly ionized UCl_4 molecules, which had masses of $A_1 = 378$ for $^{238}UCl_4$ and $A_2 = 375$ for $^{235}UCl_4$. There were two types of calutrons: alpha calultrons with a magnetic field of 0.34 Tesla, and beta calutrons with a magnetic field of 0.68 Tesla. Using these numbers, the separation distance between beams of U-238 and U-235 was:

$$\Delta d_c \;\approx\; 1.2 \text{ cm} \qquad \text{for alpha calutrons with B} = 0.34 \text{ T} \tag{D.22}$$

$$\approx\; 0.6 \text{ cm} \qquad \text{for beta calutrons with B} = 0.68 \text{ T} \tag{D.23}$$

The calutrons had to be sufficiently large to contain the orbits of the uranium beams:

$$d_c \;\approx\; 3.1 \text{ m} \qquad \text{for alpha calutrons with B} = 0.34 \text{ T} \tag{D.24}$$

$$\approx\; 1.5 \text{ m} \qquad \text{for beta calutrons with B} = 0.68 \text{ T} \tag{D.25}$$

German electromagnetic separators would almost certainly have had roughly comparable sizes and separation distances.

Fundamental physics can also give a ballpark estimate for the number of electromagnetic separators that would be required to achieve a given U-235 production rate. If N is the number of independent uranium ion beams, I is the current per beam in Amps, and $e \approx 1.602 \times 10^{-19}$ Coulombs is the electric charge of singly charged ions in the beam, the total number of ions per second is simply NI/e. Since there are $365 \times 24 \times 60 \times 60 = 3.1536 \times 10^7$ seconds per year, the annual ion production rate is

$$\frac{\text{Separated ions}}{\text{year}} \;=\; 3.1536 \times 10^7\,\frac{N\,I}{e}\;\frac{\text{ions}}{\text{year}} \tag{D.26}$$

Using Avogadro's number $N_A \approx 6.022 \times 10^{23}$ and the mass A of the ions in atomic mass units, there are N_A/A ions per gram of mass in the beam, or $1000 N_A/A$ ions/kg. Combining this information with Eq. (D.26), the annual production rate of mass is

$$\frac{\text{Separated mass}}{\text{year}} \;=\; 3.1536 \times 10^4\,\frac{N\,I\,A}{e\,N_A}\;\frac{\text{kg}}{\text{year}} \tag{D.27}$$

Space charge effects and other phenomena limit practical values of the current in the separated U-235 beam to around half a milliamp, or $I \sim 5 \times 10^{-4}$ A. (The current of the initial beam will be much larger, since most of the beam will be composed of U-238 ions.) Realistically the ion beams might operate at a somewhat lower current and would be taken offline periodically for maintenance and cleaning. Lowering the current to an average value of $I \sim 3 \times 10^{-4}$ A to account for those limitations, and using $A = 235$ for U-235, Eq. (D.27) becomes

$$\frac{\text{Separated U-235}}{\text{year}} \;\sim\; 0.023\,N\;\frac{\text{kg}}{\text{year}} \tag{D.28}$$

In early 1945, the U.S. Y-12 plant at Oak Ridge was producing approximately 0.2 kg U-235 per day, or approximately 73 kg/year. Equation (D.28) predicts a ballpark number on the order of 3200 calutron ion beams would be required for that production rate. In fact, the Y-12 plant used a two-stage process, with 2688 alpha calutron beams $(4 \times 2 \times 96 \ + \ 5 \times 4 \times 96)$ enriching to $\sim$ 20% U-235 in the first stage, and then 432 beta calutron beams $(6 \times 2 \times 36)$ further enriching that material to $\sim$ 80% U-235 [Bruce Cameron Reed 2015a, 2019]. Lumping the alpha and beta calutrons together, that makes 3120 ion beams, very close to the crude estimate from Eq. (D.28).

The maximum planned electrical power consumption of the entire Y-12 calutron plant was 200 MW (Fig. D.1031 and Table D.8). In practice, Y-12's electrical usage was generally less than that. As shown in Fig. D.1032, the total electrical consumption for Oak Ridge (Y-12 calutrons + K-25 gaseous diffusion + all other nuclear facilities + the town itself) peaked for the month ending 1 September 1945 at 200 GW hr for the month, or 0.269 GW = 269 MW time-averaged. For the 12 months ending 1 September 1945, the total electrical consumption for Oak Ridge was 1659 GW hr for the year, or 0.189 GW = 189 MW time-averaged.[27]

The total production of electrical energy in the United States increased from 161,308 GW hr for the year of 1939, or a time-average of 18.4 GW electric power production, to 271,255 GW hr for 1945, or a time-average of 31.0 GW electric power production.[28]

Thus Oak Ridge's electrical consumption during the peak final war month of August 1945 was 0.868% of the total U.S. electrical power at that time (0.269 GW/31.0 GW = 0.00868). Oak Ridge's electrical consumption averaged over that final year of the war was 0.610% of the total U.S. electrical power at that time (0.189 GW/31.0 GW = 0.00610). These figures disprove the oft-repeated myth that Oak Ridge required a large fraction of the nation's electricity. [See also Bruce Cameron Reed 2015b.]

According to the U.S. Strategic Bombing Survey (USSBS), at the end of 1944 the Greater German Reich (including modern Germany, Austria, Poland, and the Czech Republic) had a total known electrical production capacity of 22 GW, with at least 16 GW of that currently then in use despite territorial losses, extensive bombing, and ongoing repair work.[29] See pp. 2102–2104. BIOS 342 estimated a total of 23 GW for 1944 (pp. 2105–2106). Including secretive or specialized power plants for classified or dedicated projects within the Greater German Reich that were not known to the USSBS (especially in areas occupied by the Soviet Union after the war) plus the electrical production capacities of other countries that were occupied by Germany, allied with Germany, or nominally neutral but exporting aid to Germany, a reasonable estimate of the total electrical production capacity supporting the German war effort is roughly double the 22 GW figure, or $\sim$44 GW.

[29] United States Strategic Bombing Survey. 1947. *German Electric Utilities Industry Report.* pp. 1, 4, Exhibit C, Exhibit D. https://books.google.com/books?id=U9Q9TS-FtSgC

Using the average total electrical consumption of Oak Ridge during the final year of the war, Germany could have powered a fully equal facility by using:

- 1.18% of the electrical capacity known to remain in use in the Greater German Reich at the end of 1944 (0.189 GW/16 GW = 0.0118), or
- 0.859% of the known wartime electrical capacity in the Greater German Reich (0.189 GW/22 GW = 0.00859), or
- ∼0.43% of the estimated total electrical production capacity that was available to aid Germany during the war (0.189 GW/44 GW = 0.00430).

The U.S. electromagnetic separation plant was designed to produce so much U-235 because the United States planned to use that uranium in Little Boy, a gun-type fission bomb that needed over 60 kg of fuel because it did not compress the fuel and had a very low efficiency. The U.S. plant provided enough uranium for approximately one bomb of that design per year.

The sources that describe the German fission bomb design all indicate that it was an implosion bomb, which compresses the fuel, is much more efficient than a gun-type bomb, and therefore requires roughly 1/10 as much fuel as a gun-type bomb. If a German enrichment facility were designed to produce enough U-235 for one full-sized bomb per year (or several test bombs with smaller amounts of fuel and smaller explosive yields, as described by the sources), that German enrichment plant could have been roughly 1/10 the size of the U.S. Y-12 plant, as extrapolated in Table D.8. If that same production capacity were distributed among several production plants to minimize the risk of Allied bombing (p. 4400), each plant would have been even smaller.

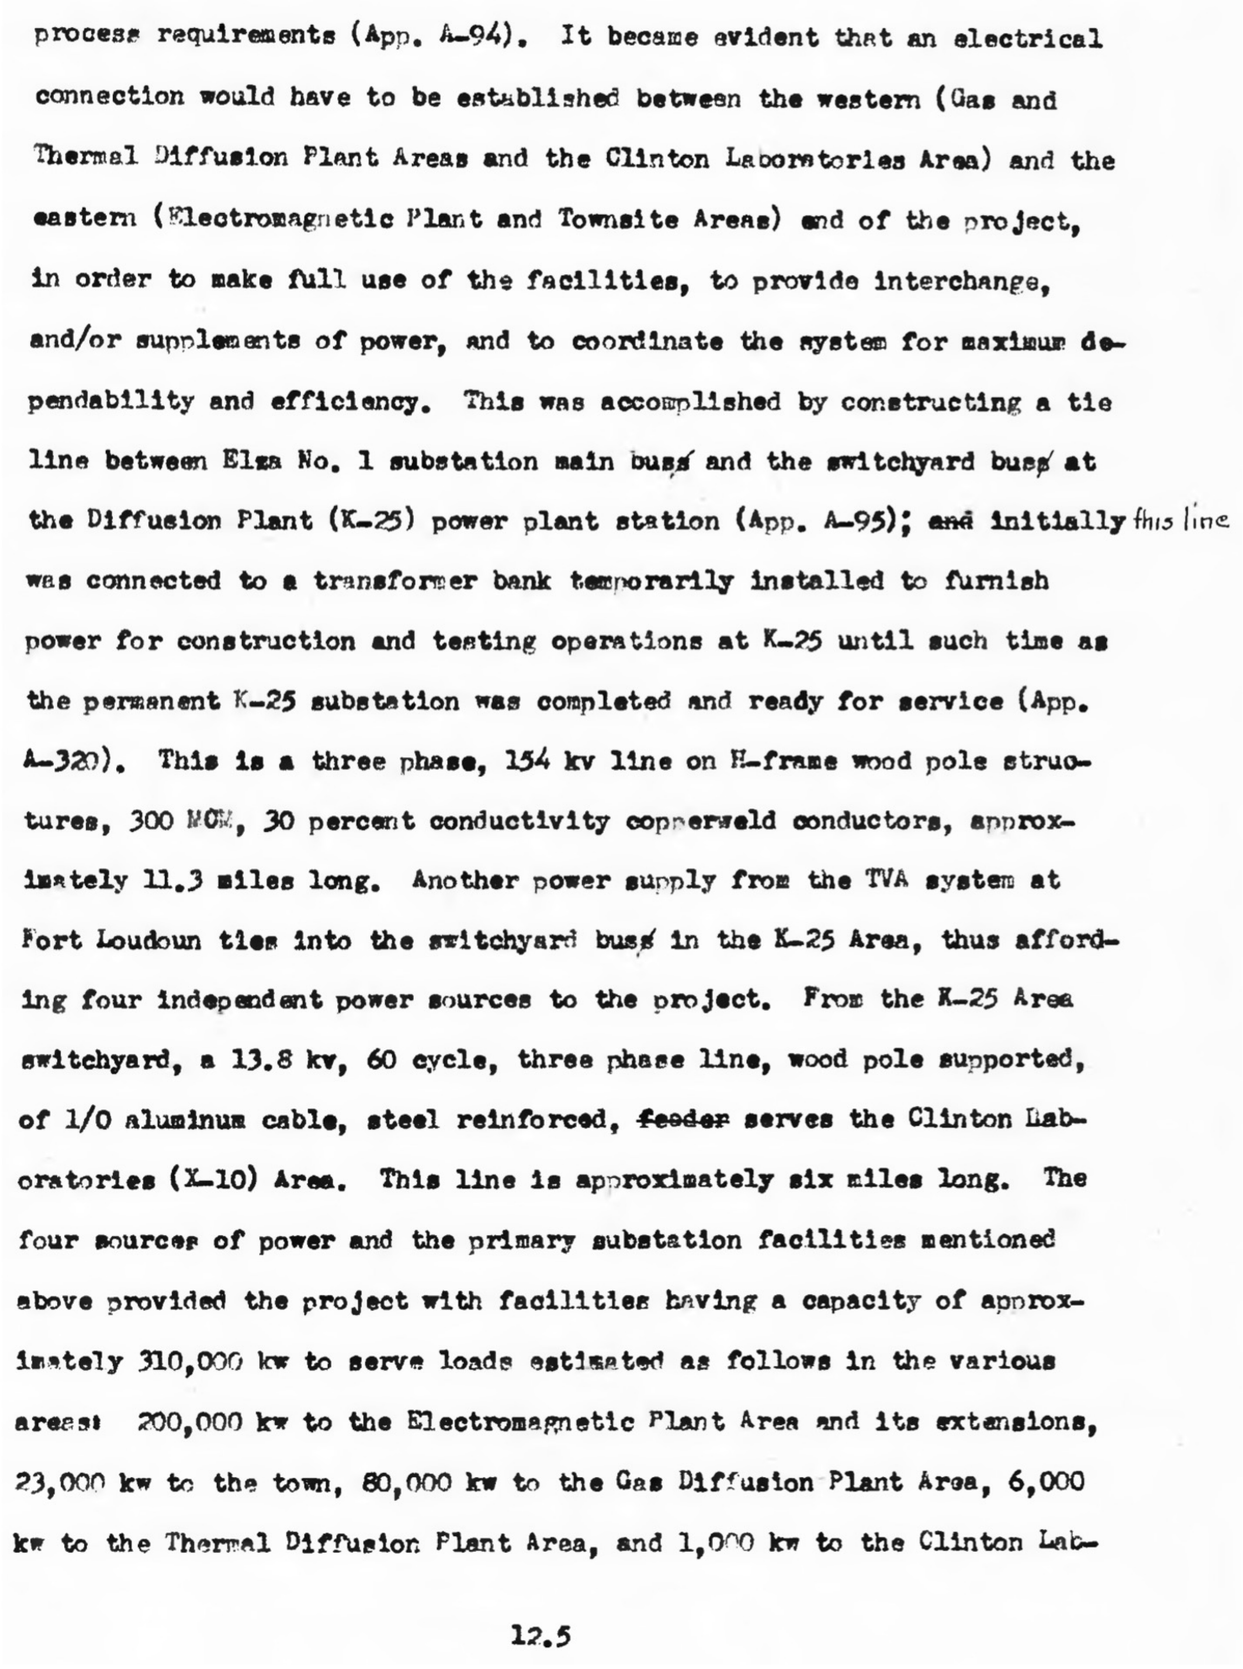
German enrichment facilities 1/10 the total size of Oak Ridge would have used:

- 0.118% of the electrical capacity known to remain in use in the Greater German Reich at the end of 1944, or
- 0.0859% of the known wartime electrical capacity in the Greater German Reich, or
- ∼0.043% of the estimated total electrical production capacity that was available to aid Germany during the war.

Due to the huge power consumption of the electromagnets, electromagnetic separators like the Y-12 calutrons are the least energy-efficient uranium enrichment method that has been employed on an industrial scale. As analyzed next, Germany developed more energy-efficient enrichment methods (gaseous diffusion and especially uranium gas centrifuges), so plants using those methods would have consumed even less of the total German electrical capacity than has been calculated above.

Characteristic	**U.S. Y-12 Plant**	**Hypothetical German Plant**
^{235}U production rate	73 kg/year	∼ 7 kg/year
Number of ion beams	3120	∼ 310
Number of workers	22,482	∼ 2,200
Facility floor space	∼ 400,000 m^2	∼ 40,000 m^2
Electric power consumption	200 MW	∼ 20 MW
Cost (1940s U.S. dollars)	$477,631,000	∼ $48,000,000

Table D.8: Known characteristics of the U.S. electromagnetic separation plant and extrapolated characteristics of a hypothetical German electromagnetic separation plant.



process requirements (App. A-94). It became evident that an electrical connection would have to be established between the western (Gas and Thermal Diffusion Plant Areas and the Clinton Laboratories Area) and the eastern (Electromagnetic Plant and Townsite Areas) end of the project, in order to make full use of the facilities, to provide interchange, and/or supplements of power, and to coordinate the system for maximum dependability and efficiency. This was accomplished by constructing a tie line between Elza No. 1 substation main bus~~s~~ and the switchyard bus~~s~~ at the Diffusion Plant (K-25) power plant station (App. A-95); ~~and~~ initially this line was connected to a transformer bank temporarily installed to furnish power for construction and testing operations at K-25 until such time as the permanent K-25 substation was completed and ready for service (App. A-320). This is a three phase, 154 kv line on H-frame wood pole structures, 300 MCM, 30 percent conductivity copperweld conductors, approximately 11.3 miles long. Another power supply from the TVA system at Fort Loudoun ties into the switchyard bus~~s~~ in the K-25 Area, thus affording four independent power sources to the project. From the K-25 Area switchyard, a 13.8 kv, 60 cycle, three phase line, wood pole supported, of 1/0 aluminum cable, steel reinforced, ~~feeder~~ serves the Clinton Laboratories (X-10) Area. This line is approximately six miles long. The four sources of power and the primary substation facilities mentioned above provided the project with facilities having a capacity of approximately 310,000 kw to serve loads estimated as follows in the various areas: 200,000 kw to the Electromagnetic Plant Area and its extensions, 23,000 kw to the town, 80,000 kw to the Gas Diffusion Plant Area, 6,000 kw to the Thermal Diffusion Plant Area, and 1,000 kw to the Clinton Lab-

B. Gaseous Diffusion and the Isotope Sluice

If a gas contains two isotopes with different masses m_{heavy} and m_{light} but the same temperature T, the thermal velocity of the lighter isotope will be $\sqrt{m_{\text{heavy}}/m_{\text{light}}}$ times faster than that of the heavier isotope ($v \sim \sqrt{k_B T/m}$). If pressurized gas is forced to diffuse through a barrier containing small pores, the lighter isotope will thus diffuse $\sqrt{m_{\text{heavy}}/m_{\text{light}}}$ times faster than the heavier isotope, permitting a small amount of enrichment per barrier stage, as shown in Fig. D.1030(b). By connecting many such diffusion barriers in series, significant amounts of enrichment can be obtained.

The only compound of uranium suitable for enrichment by gaseous diffusion is uranium hexafluoride (UF_6), which is solid below 56^oC but gaseous above that temperature. UF_6 is very chemically reactive with water and highly corrosive to organic materials (except Teflon) and most metals except nickel and aluminum, so the diffusion barriers are generally formed from porous nickel or possibly porous aluminum. The fluorine mass per molecule ($6 \times 19.0 = 114$) is small enough not to completely obscure the small mass difference between ^{235}U and ^{238}U. Including the fluorine, the ratio of the diffusion velocities v_{light} of $^{235}UF_6$ and v_{heavy} of $^{238}UF_6$ is

$$\frac{v_{\text{light}}}{v_{\text{heavy}}} = \sqrt{\frac{m_{\text{heavy}}}{m_{\text{light}}}} = \sqrt{\frac{238+114}{235+114}} \approx 1.0043 \tag{D.29}$$

In practice, at least 1000 pressurized barrier stages in series are required to obtain reactor-level (2–4%) enrichment, and many more to obtain bomb-level (> 50%) enrichment. The United States employed this method during and for quite some time after World War II, but it is very cumbersome and energy-intensive, due to the large number of stages and the energy required to pressurize each stage. Thus almost all enrichment nowadays uses centrifugation, which is much more energy-efficient [Benedict et al. 1981; Bruce Cameron Reed 2015a, 2019].

Gustav Hertz pioneered gaseous diffusion enrichment, starting before 1923, continuing to work in Germany throughout the Third Reich (even though he was partially Jewish), and playing a critical role in uranium enrichment in the Soviet Union after the war (p. 3618). Historians should investigate whether there may have been any secret programs in wartime Germany to mass-produce and operate copies of Hertz's technology, either by Hertz or anyone else.

Whereas Erich Bagge's isotope sluice had its own unique method of operation (p. 3651), ultimately its isotope separation was due to the same velocity ratio between light and heavy isotopes as Eq. (D.29) for gaseous diffusion. Thus Bagge's isotope sluice would have required a number of stages or repeated steps comparable to gaseous diffusion in order to achieve large-scale enrichment. Again, historians should dig more deeply to determine if such devices may have been mass-produced and operated anywhere within the Third Reich.

C. Gas Centrifuges

Centrifuges are routinely used to separate liquids of different densities, but specially designed centrifuges can also separate gas molecules of different masses. As with gaseous diffusion, the uranium is in the form of hot corrosive UF_6, so centrifuge components must be made from resistant materials such as aluminum, nickel, and Teflon [Benedict et al. 1981; Glaser 2008; Kemp 2009, 2012, 2017].

Konrad Beyerle, Wilhelm Groth, Paul Harteck, Werner Holtz, Werner Schwietzke, and other scientists and engineers in the German nuclear program developed a succession of improved gas centrifuges during the war (p. 3494). According to official histories, these centrifuges were one-of-a-kind prototypes that were simply used for research purposes. Yet there is evidence that these centrifuge designs were secretly mass-produced and used at other locations in the Third Reich (pp. 3544, 3670). If that was indeed the case, they could have been a highly effective method of producing enriched uranium for both fission bombs and fission reactors.

After the war, German gas centrifuge technology (along with the German experts on that technology) was ultimately adopted by the Soviet Union, western Europe, the United States, and the rest of the world, displacing the much less efficient and much more expensive enrichment technologies that the United States had developed during the war.

Figure D.1030(c) shows a highly simplified illustration of a gas centrifuge. The centrifuge is essentially a long rotating drum, and UF_6 is brought in along the axis of rotation. Heavier $^{238}\mathrm{UF}_6$ molecules tend to move toward the outer walls of the centrifuge, while lighter $^{235}\mathrm{UF}_6$ is more buoyant and tends to remain closer to the axis. Of course, the two isotopes still intermingle, but gas somewhat depleted of $^{235}\mathrm{U}$ can be removed near the outer wall of the cylinder, and gas somewhat enriched for $^{235}\mathrm{U}$ can be drawn off closer to the axis. The centrifuge operates in a continuous fashion with fresh gas entering the chamber and old gas leaving it.

The enrichment that can be achieved by one such centrifuge can be estimated by a simple model. During operation, most of the gas is in a thin layer adjacent to the outer wall. If the wall is at radius R and rotates at velocity v, gas molecules with mass m immediately adjacent to it will move at the same velocity and have kinetic energy $mv^2/2$. If molecules move to a radial position r closer to the axis, in equilibrium they must assume a rotation velocity $(r/R)v$, or a kinetic energy $(r/R)^2 mv^2/2$. The difference in kinetic energies between molecules at radii r and R is

$$E \;=\; \left(1 - \frac{r^2}{R^2}\right)\frac{mv^2}{2} \tag{D.30}$$

From statistical physics, in a thermal distribution the density of particles n with different energies E varies like $n(E) = n(0)\exp(-E/k_B T)$. In the rotating frame of reference at the outer wall, molecules adjacent to the wall have zero energy and molecules that climb "higher" (closer to the axis) have energy E from Eq. (D.30) relative to that. Therefore the ratio of the densities at radii r and R is

$$\frac{n_r}{n_R} \;=\; \exp\left[-\frac{mv^2}{2k_B T}\left(1 - \frac{r^2}{R^2}\right)\right] \tag{D.31}$$

By applying Eq. (D.31) first to the densities of light molecules ($^{235}\mathrm{UF}_6$) and second to the densities of heavy molecules ($^{238}\mathrm{UF}_6$), and then by taking the ratio of those densities, one finds:

$$\frac{(n_{\text{light}}/n_{\text{heavy}})_r}{(n_{\text{light}}/n_{\text{heavy}})_R} \quad = \quad \exp\left[\frac{(m_{\text{heavy}} - m_{\text{light}})v^2}{2k_B T}\left(1 - \frac{r^2}{R^2}\right)\right] \tag{D.32}$$

Note that the amount of separation that can be produced by centrifugation in Eq. (D.32) only depends on the difference of the isotope masses, not their ratio as was the case for gaseous diffusion in Eq. (D.29). The difference in masses between uranium isotopes is several mass units, yet their ratio is only a minute fraction over unity, so centrifugation is inherently superior to gaseous diffusion for uranium enrichment.

To better see the efficacy of centrifugation, one can use Eq. (D.32) with a mass difference of 3 atomic mass units (the difference between uranium-238 and uranium-235) and a temperature of 340^oK (just comfortably above the sublimation point of UF_6):

$$\frac{(n_{\text{light}}/n_{\text{heavy}})_r}{(n_{\text{light}}/n_{\text{heavy}})_R} \quad \approx \quad \exp\left[\left(\frac{v}{1370\ \text{m/sec}}\right)^2\left(1 - \frac{r^2}{R^2}\right)\right] \tag{D.33}$$

Using rough estimates of $v = 500$ m/sec (4800 revolutions per minute and $R = 0.1$ m) and $r/R = 0.8$, Eq. (D.33) yields

$$\frac{(n_{\text{light}}/n_{\text{heavy}})_r}{(n_{\text{light}}/n_{\text{heavy}})_R} \quad \approx \quad 1.049 \tag{D.34}$$

As shown by Eq. (D.34) vs. Eq. (D.29), the enrichment that can be obtained by one stage of gas centrifugation is $\sim$ 10x greater than that obtained from one stage of gaseous diffusion. Therefore, enrichment of natural uranium to reactor-grade material can be accomplished by $\sim$ 100 gas centrifuge stages vs. $\sim$ 1000 gaseous diffusion stages.

Each gas centrifuge also uses at least $\sim$ 2x less energy than each gaseous diffusion stage (due to the large pressure loss across each diffusion barrier), so enrichment via centrifuges consumes at least $\sim$ 20x less energy than enrichment via gaseous diffusion.

Because of these advantages, centrifuges are now the worldwide standard for enrichment (pp. 3549–3553).

Actual gas centrifuges are considerably more complicated than indicated by the schematic illustration in Fig. D.1030(c) or the simplified calculations above. Among other complexities, they include mechanisms to induce gas circulation within the chamber to optimize isotope separation while allowing for continuous throughput [Benedict et al. 1981; Glaser 2008; Kemp 2009, 2012, 2017].

Using information from these references and comparing to Table D.8 for electromagnetic separators, Table D.9 shows the extrapolated characteristics of a hypothetical German centrifuge separation plant. For this table, it has been assumed that the plant requires less than 1 worker per shift (3 shifts/day) per centrifuge, and less than 9 m^2 of floor space per centrifuge. For the same uranium enrichment rate, a centrifuge plant should have less than the cost of an electromagnetic separation plant (which has expensive electromagnets and ion beams), and less than 1/20 the electrical consumption of a gaseous diffusion plant (which in turn has less electrical consumption than an electromagnetic separation plant).

A German centrifuge separation plant as outlined in Table D.9 would have consumed less than 1 MW of electrical power, which corresponds to:

- Less than 0.00625% of the 16 GW electrical capacity known to remain in use in the Greater German Reich at the end of 1944, or
- Less than 0.00455% of the 22 GW known wartime electrical capacity in the Greater German Reich, or
- Less than ∼0.00227% of the ∼44 GW estimated total electrical production capacity that was available to aid Germany during the war.

If that same production capacity were distributed among several production plants to minimize the risk of Allied bombing (as confirmed in 1944 by the leading German industrialist Adolf Schneider, p. 4400), each plant would have been even smaller than indicated in Table D.9.

Historians need to clarify exactly how far gas centrifuge technology progressed in Germany during the war, how many gas centrifuges were used and where they were located, and how much uranium of what enrichment percentage was produced in the Third Reich. The critical role of German scientists and engineers in spreading this technology to other countries after the war also deserves to be much better known than it currently is.

Characteristic	**Hypothetical German Plant**
^{235}U production rate	$\sim$ 7 kg/year
Number of centrifuges	$\sim$ 467
Number of workers	< 1,400
Facility floor space	< 4,200 m^2
Electric power consumption	< 1 MW
Cost (1940s U.S. dollars)	< $48,000,000

Table D.9: Extrapolated characteristics of a hypothetical German centrifuge separation plant.

D. Laser Isotope Separation

By 1930 or earlier, groups of scientists within the German-speaking world began developing two (apparently) separate technologies: (1) photochemical methods of separating isotopes using inefficient plasma lamps (p. 3664) and (2) lasers as an efficient monochromatic light source (Section C.3). During and after the Third Reich, both technologies were transferred to other countries, where decades later they were combined to create laser isotope separation.

The mass of the nucleus has a very small but measurable effect on the energy levels of orbiting electrons, termed the hyperfine interaction in quantum physics, so different isotopes of the same element have slightly different energy levels and thus can be excited by photons at slightly different wavelengths. As shown in Fig. D.1030(d), this principle can be used to separate different isotopes when they are in the form of either individual atoms or molecules:

- In Atomic Vapor Laser Isotope Separation (AVLIS), pure uranium metal is heated to 2300^oC to vaporize it. Due to hyperfine interactions, the wavelength to elevate one electron to an excited state is 502.74 nm for ^{235}U but 502.73 nm for ^{238}U. Therefore a dye laser precisely tuned to 502.74 nm can excite ^{235}U atoms in the vapor without affecting ^{238}U. Photons with a wavelength of 262.5 nm from a second laser have enough energy to ionize (completely free the one excited electron) the excited ^{235}U but not the unexcited ^{238}U atoms. Electric and/or magnetic fields can remove the singly charged ^{235}U while leaving the neutral ^{238}U, as illustrated in Fig. D.1030(d). In practice, charge exchange between the two isotopes leads to some neutral ^{235}U and some charged ^{238}U, limiting the enrichment that can be achieved by one pass through an AVLIS system. Even so, natural uranium can be enriched to reactor-grade levels in one or at most a few passes, versus $\sim$ 100 for centrifugation and $\sim$ 1000 for gaseous diffusion. Moreover, AVLIS is precise enough that it can even harvest the small amount of ^{235}U that remains in the depleted uranium tails left by diffusion or centrifugation enrichment plants. For a given quantity of uranium and degree of enrichment, the input energy cost of AVLIS is roughly comparable to that of gas centrifuges, while the equipment cost is potentially lower, since the cheaper cost of a centrifuge vs. the laser setup is outweighed by the far larger number of centrifuges required for comparable enrichment.

- In Molecular Laser Isotope Separation (MLIS), UF_6 gas is used, just as it is for enrichment by diffusion and centrifugation. This is a great advantage over AVLIS, since UF_6 must only be heated to 56^oC to become a gas (vs. 2300^oC for pure uranium). However, UF_6 molecules must then be cooled to 30–77^oK to put them into their vibrational ground state, which largely conflicts with the goal of keeping them in the gaseous phase instead of solid phase [Benedict et al. 1981]. If this can be accomplished, photons from a carbon dioxide laser with a wavelength of 16 μm can be used to boost $^{235}UF_6$ (but not $^{238}UF_6$) molecules to the first excited vibrational state. Photons with a wavelength of 308 nm (or in some implementations, an infrared wavelength) from an excimer laser can then dissociate the excited $^{235}UF_6$ molecules (but not the unexcited$^{238}UF_6$ molecules) into UF_5 plus atomic fluorine. Under these conditions, UF_5 is a solid, so ^{235}U precipitates out in the solid pentafluoride phase, whereas ^{238}U remains in the gaseous hexafluoride phase. An improved version of this process, Separation of Isotopes by Laser Excitation (SILEX) apparently overcomes the previously conflicting requirements of MLIS by using the difference in electrical charge between the two laser-irradiated isotopes to separate them, but details of SILEX are still classified.

Much more archival research is needed to explore how far wartime German programs on photochemical isotope enrichment progressed, how far wartime German programs on lasers progressed, whether there were any connections between those two wartime programs, and exactly how those wartime German programs influenced postwar work in other countries.

D.15.3 Breeding Methods to Produce Pu-239 or U-233

As discussed in the previous section, enrichment of uranium is difficult due to the fact that highly fissionable uranium-235 and relatively inert uranium-238 are chemically identical and very close in mass. In contrast, one can use a fission reactor or a particle accelerator to breed highly fissionable plutonium-239 from natural uranium-238, or highly fissionable uranium-233 from natural thorium-232, then exploit the differences in chemical properties between the bred fission fuel and the natural starting material in order to rapidly purify the fuel for a bomb.[30] This section discusses (a) the fundamental nuclear physics of creating plutonium-239 and uranium-233, (b) how a fission reactor could be used to breed either fuel, (c) how a particle accelerator could be used to breed either fuel, and (d) what chemical processes could be used to separate the bred fuel from the natural starting material.

A. Fundamental Nuclear Physics of Creating Plutonium-239 and Uranium-233

By mass, approximately 99.275% of natural uranium is uranium-238 ($^{238}_{92}$U), which will not fission unless it is hit with high-energy (at least a few MeV) neutrons. However, if uranium-238 is irradiated with low energy neutrons, such as in a fission reactor, it can absorb a neutron (n) and release the excess energy as a gamma (γ) ray, then undergo two successive beta (β) decays to become plutonium-239 ($^{239}_{94}$Pu), which is an excellent fission fuel:

$$^{238}_{92}\mathrm{U} + \mathrm{n} \xrightarrow{(\mathrm{n},\gamma)} {}^{239}_{92}\mathrm{U} \;\; \beta \xrightarrow{23.5\ \mathrm{min}} {}^{239}_{93}\mathrm{Np} \;\; \beta \xrightarrow{2.36\ \mathrm{days}} {}^{239}_{94}\mathrm{Pu} \qquad \text{(D.35)}$$

The two beta decays to plutonium-239 happen within a few days, which means that they tend to happen before the fuel is removed from the breeding reactor, or within a few days of being removed from the breeding reactor. Many highly radioactive isotopes with short half-lives are created by fission of uranium-235 in the fuel, so it is customary to let the fuel "cool off" for a month or so after being removed from the breeder reactor before it is processed by people. Since the German nuclear program would have had a great sense of urgency and likely did not value the lives of its low-level workers, it might have processed irradiated fuel with a much shorter cooling off period.

If uranium-238 were irradiated with low-energy neutrons for a long enough period of time, most of it would convert to plutonium-239. Unfortunately, two problems greatly limit how long the uranium-238 can be exposed to neutrons, and therefore how much of it can be converted to plutonium-239. If significant amounts of plutonium-239 build up in the sample, slow neutrons will make them undergo fission reactions and burn up before they can be removed and purified for use in a bomb. Yet even before that effect becomes a problem, a second constraint is even more limiting: plutonium-239 that absorbs a neutron but does not fission becomes plutonium-240:

$$^{239}_{94}\mathrm{Pu} + \mathrm{n} \longrightarrow {}^{240}_{94}\mathrm{Pu} + \gamma \qquad \text{(D.36)}$$

---

[30] Neptunium-237 fission fuel [Sanchez et al. 2008] could also have been bred with a reactor or accelerator (e.g., by knocking a neutron out of U-238), although it probably would have been more difficult to produce in quantity than Pu-239 or U-233 [Benedict et al. 1981].

Plutonium-240 is chemically identical to plutonium-239 and only one atomic mass unit different in mass, making these plutonium isotopes even harder to separate from each other than uranium-235 and uranium-238 (with three mass units of difference). Thus most bred plutonium-239 will contain some amount of contaminating plutonium-240.

Whereas plutonium-239 essentially only fissions when hit with a neutron, and therefore will wait to release its energy in a chain reaction in a bomb, plutonium-240 sometimes fissions spontaneously. The neutrons that are constantly emitted by this spontaneous fission of plutonium-240 could initiate a fission chain reaction too soon as the critical mass of a bomb is being brought together, greatly decreasing the net energy release of the bomb. A gun-type (Little Boy) bomb design assembles the critical mass too slowly to overcome this problem; only an implosion (Fat Man) bomb design can assemble the critical mass rapidly enough before the spontaneous fission events hinder the process.

Even with an implosion bomb design, it is important to minimize the amount of plutonium-240 contamination and the spontaneous fission rate, so for weapons production, typically uranium-238 is irradiated with neutrons only until $<0.01\%$ of the uranium-238 has become plutonium-239. That means that an enormous amount of (highly radioactive) irradiated uranium must be chemically processed to recover a small amount of plutonium.

In addition to uranium, another actinide that can be mined in useful quantities is thorium, virtually all of which is thorium-232 ($^{232}_{90}\mathrm{Th}$). While thorium-232 itself is not a good fission fuel, if it is irradiated with low energy neutrons, such as in a fission reactor, it can absorb a neutron and release the excess energy as a gamma ray, then undergo two successive beta decays to become uranium-233 ($^{233}_{92}\mathrm{U}$), which is an excellent fission fuel:

$$^{232}_{90}\mathrm{Th} + \mathrm{n} \xrightarrow{(\mathrm{n},\gamma)} {}^{233}_{90}\mathrm{Th} \;\; \overset{\beta\ \ 21.8\ \mathrm{min}}{\longrightarrow} \;\; {}^{233}_{91}\mathrm{Pa} \;\; \overset{\beta\ \ 27.0\ \mathrm{days}}{\longrightarrow} \;\; {}^{233}_{92}\mathrm{U} \tag{D.37}$$

The processes for breeding uranium-233 in Eq. (D.37) and for breeding plutonium-239 in Eq. (D.35) are clearly highly similar, though beta decay to uranium-233 takes over ten times longer, mandating that the fuel sit for at least a month or so after being removed from the breeder reactor.

Just as the buildup of an undesirable contaminant limits how much plutonium-239 can be bred from uranium-238, the buildup of another undesirable contaminant limits how much uranium-233 can be bred from thorium-232. Neutron bombardment can actually remove a neutron from the highly desirable uranium-233, converting it to the highly undesirable uranium-232:

$$^{233}_{92}\mathrm{U} + \mathrm{n} \longrightarrow {}^{232}_{92}\mathrm{U} + 2\mathrm{n} \tag{D.38}$$

Uranium-232 undergoes a series of alpha (α) decays with a net half-life of roughly 70 years, producing thallium-208 which emits intense gamma rays. Although that process does not interfere with fission reactions, steady decay of contaminating uranium-232 into gamma-emitting thallium-208 means that bred uranium-233 is intensely radioactive and harmful to people working with it, and remains that way for many years after its creation. Again, if the German nuclear program did not value the lives of its low-level workers, this concern may not have limited their use of this method of fission fuel production.

B. Breeding in a Fission Reactor to Produce Pu-239 or U-233

German scientists knew how to breed plutonium-239 or uranium-233 in a fission reactor, had two reactors on the brink of criticality by the end of the war (the Heisenberg group's Berlin/Haigerloch pile and the Diebner group's Gottow/Stadtilm pile), and may have had other reactors that actually became operational during the war (p. 3794). Such reactors could have used heavy water (D_2O) and/or pure graphite (without neutron-absorbing boron impurities) as a moderator to slow down the neutrons emitted by the fission reactions, so that the neutrons would be much more likely to create a chain reaction and also to breed plutonium-239 (or uranium-233).

In the wartime U.S. nuclear program, the main reactors breeding plutonium were three reactors in Hanford, Washington, dubbed reactors B, D, and F. When fully operational, each of those reactors produced approximately 250 MW of thermal power from approximately 250 tons of natural uranium, or about 1 MW/ton [Bruce Cameron Reed 2015a, 2019]. None of that energy was converted to electricity as in a modern power reactor; water was used to cool the reactor and carry the heat away, so the reactors needed direct access to large quantities of fresh water.

At that power, each reactor bred approximately 0.19 kg of plutonium-239 per day, or approximately 69 kg per year. To limit the production of plutonium-240, the 250 tons of reactor fuel was removed after approximately 100 days, and then the reactor was restarted with fresh natural uranium fuel [Bruce Cameron Reed 2015a, 2019]. Comparing the plutonium-239 production rate of 0.19 kg/day to the rate of using natural uranium, 250 tons/100 days = 2.5 tons/day, the amount of plutonium-239 bred per ton of natural uranium was

$$\frac{\text{Bred Pu-239}}{\text{Natural uranium}} \approx \frac{0.19 \text{ kg/day}}{2.5 \text{ tons/day}} \approx 0.076 \ \frac{\text{kg}}{\text{ton}} \tag{D.39}$$

Note that the amount of fissionable plutonium-239 produced from a ton of natural uranium is roughly 100 times smaller than the maximum amount of fissionable uranium-235 (7.2 kg) that could be extracted from that same ton of natural uranium via the enrichment methods of the previous section. Again, this low level of production is due to the need to avoid creating much plutonium-240 in the fuel. As a result, a fission fuel breeding program would use ∼100 times more uranium than a fission fuel enrichment program (unless the irradiated uranium were reused in the breeder reactor after the plutonium had been removed, but that would be even more time consuming, and a wartime program would presumably be under extreme time pressure).

Counterbalancing that disadvantage is the advantage that a breeder reactor and the accompanying chemical purification processes handle fission fuel in a very dense solid or liquid state, whereas enrichment methods handle fission fuel in a far less dense gaseous or plasma state. Therefore the equipment for breeding would be much more compact, and could potentially be built and operated by fewer people, than the equipment for enrichment.

Characteristic	**Approximate value (scales linearly)**
Thermal power	25 MW
Reactor core volume	100 m^3
Moderator	150 tons of graphite, or 80 tons of heavy water, or some of both
Natural uranium in reactor	25 tons
Replace uranium every	100 days
Uranium consumption rate	91 tons/year
Plutonium production rate	6.9 kg/year
Cost (1940s U.S. dollars)	$6,000,000

Table D.10: Approximate characteristics of a breeder reactor for producing plutonium-239.

As long as the reactor is large enough to have a self-sustaining fission chain reaction, these characteristics can be scaled up or down in a linear fashion, using the approximate numbers in Table D.10 as a basis for reference [Kemp 2005; OTA 1977]. For example, if each Hanford reactor held 250 tons of natural uranium and produced approximately 69 kg of plutonium-239 per year, a hypothetical German reactor holding approximately 22 tons of natural uranium could produce approximately 6 kg of plutonium-239 per year, enough for one full-sized ∼20 kiloton implosion bomb (like the U.S. Gadget and Fat Man bombs) per year. From Eq. D.39, producing 6 kg of plutonium would require processing approximately 79 tons of uranium.

Thorium-232 is useful for breeding uranium-233 but cannot sustain a fission chain reaction on its own. The reactor would need to contain natural uranium or uranium enriched in uranium-235. On the order of ∼90% of the neutrons from the uranium would be needed to sustain the chain reaction, so only ∼10% of the neutrons could be spared to breed uranium-233 from thorium-232, and hence only ∼10% of the total fuel in the reactor could be thorium. Thus a fission reactor for breeding uranium-233 might be ∼10 times larger in volume or mass than a reactor for breeding plutonium-239. (Of course, plutonium would also be bred within the ∼90% of the reactor fuel that was uranium, and that plutonium could be extracted as well.) For this reason, it seems likely that the German nuclear program would have generally preferred producing plutonium-239 instead of uranium-233, although scientists may have certainly tried uranium-233 (especially because of the large amount of thorium that was available to the German nuclear program).

C. Breeding with an Accelerator to Produce Pu-239 or U-233

Even without a fission reactor, it is possible to produce significant amounts of Pu-239 or U-233 via a process called electronuclear breeding. In this process, a particle accelerator fires a beam of high-energy charged particles (typically protons, deuterons, or electrons with a kinetic energy of many millions of electron-volts or MeV) at a target containing U-238 or Th-232. When those energetic charged particles strike the nuclei of the target material, they knock some neutrons free, and those neutrons are absorbed by U-238 atoms to become Pu-239 atoms, or by Th-232 atoms to become U-233 atoms. In more sophisticated and efficient systems, the target may also contain an initial layer of lithium or beryllium, which are especially good at releasing neutrons when struck by high-energy charged particles. If furthermore the target is immersed in a neutron moderator (such as heavy water or pure graphite) and surrounded by a neutron reflector (such as beryllium), each neutron that is originally generated can lead to a cascade of several more neutrons by subcritical fission reactions, yielding several atoms of bred fuel per charged particle in the beam.

If the target is lithium without uranium or thorium, electronuclear breeding can be used to produce tritium, which would be very useful for fusion boosting of fission bombs or for creating a hydrogen bomb.

Electronuclear breeding was seriously pursued by the United States and other countries after World War II, and even now is of concern as a proliferation risk for how new countries could produce nuclear weapons.[31] German scientists knew how to breed plutonium-239 (or uranium-233) in a particle-accelerator-driven electronuclear system, and built and operated suitable accelerator systems (pp. 3954–4022 and 4504–4510) that appear to have been a high priority part of the wartime German nuclear program.

Simple physics can give a ballpark estimate for the amount of Pu-239 or U-233 that could be produced by electronuclear breeding. If N is the number of particle accelerators, I is the beam current per particle accelerator, and $e \approx 1.602 \times 10^{-19}$ Coulombs is the electric charge of particles (protons, deuterons, or electrons) in the beam, the total number of charged particles per second is simply NI/e. Since there are $365 \times 24 \times 60 \times 60 = 3.1536 \times 10^7$ seconds per year, the annual charged particle production rate is

$$\frac{\text{Charged particles}}{\text{year}} = 3.1536 \times 10^7 \, \frac{N\,I}{e} \, \frac{\text{particles}}{\text{year}} \tag{D.40}$$

Let η be the number of bred Pu-239 or U-233 atoms per accelerated charged particle, or in other words the efficiency of converting accelerated charged particles to neutrons and then letting those neutrons be captured to breed the desired atoms. Thus the atom breeding rate is

$$\frac{\text{Bred atoms}}{\text{year}} = 3.1536 \times 10^7 \, \frac{N\,I\,\eta}{e} \, \frac{\text{atoms}}{\text{year}} \tag{D.41}$$

Using Avogadro's number $N_A \approx 6.022 \times 10^{23}$ and the mass A of the bred atoms in atomic mass units, there are N_A/A atoms per gram of mass, or $1000N_A/A$ atoms/kg. Combining this information with Eq. (D.41), the annual production rate of mass is

$$\frac{\text{Bred mass}}{\text{year}} = 3.1536 \times 10^4 \, \frac{N\,I\,\eta\,A}{e\,N_A} \, \frac{\text{kg}}{\text{year}} \tag{D.42}$$

---

[31] Barashenkov et al. 1987; Barber and George 1959; Chichester 2009; Kemp 2005; Livdahl 1981; Magill and Peerani 1999; Riendeau et al. 1999; Van Atta 1977.

Space charge effects and other phenomena generally limit practical values of the beam current to around a milliamp, or $I \approx 10^{-3}$ amp [Kemp 2005]. For 10 accelerators operating in parallel to breed Pu-239 ($A = 239$) with an efficiency $\eta \sim 1$, Eq. (D.42) becomes

$$\frac{\text{Bred Pu-239}}{\text{year}} \sim 0.78 \ \frac{\text{kg}}{\text{year}} \tag{D.43}$$

Similarly, for 10 accelerators with $I \approx 10^{-3}$ amp breeding U-233 ($A = 233$) with an efficiency $\eta \sim 1$, Eq. (D.42) gives

$$\frac{\text{Bred U-233}}{\text{year}} \sim 0.76 \ \frac{\text{kg}}{\text{year}} \tag{D.44}$$

Likewise, for 10 accelerators with $I \approx 10^{-3}$ amp breeding tritium ($A = 3$) with an efficiency $\eta \sim 1$, Eq. (D.42) becomes

$$\frac{\text{Bred tritium}}{\text{year}} \sim 9.8 \ \frac{\text{g}}{\text{year}} \tag{D.45}$$

From these crude estimates, a year-long electronuclear breeding program could produce ~ 0.8 kg of plutonium-239 or uranium-233, or ~ 10 g of tritium. The equations reveal several ways to improve this output:

- The German program could have built and operated more than 10 particle accelerators in parallel. That is not unreasonable, considering that the United States built and operated 3120 calutron ion beams at Oak Ridge for U-235 enrichment.
- The beam current might have been increased. 1 mA per beam is a representative value but not a hard limit. Increasing the beam current by a factor of two or three would correspondingly increase the amount of bred fission fuel by a factor of two or three.
- The German program might have operated particle accelerators for longer than a year. If the accelerators began operation two years before the end of the war, twice as much fuel could have been produced.
- Most importantly, the efficiency η could have been optimized. Depending on the conditions, the efficiency could be as low as $\eta \sim 0.001$ or as high as $\eta \sim 100$ [Kemp 2005]. Using the highest possible beam energy, choosing the best type of charged particle for the beam (in some cases, deuterons work better than protons or electrons), and using a neutron-multiplying target could give efficiencies toward the upper end of that range. A neutron-multiplying target would essentially be a small, subcritical fission reactor, for example chunks of unenriched uranium metal immersed in heavy water and surrounded by a beryllium reflector. Whereas the reactor would not be large enough to create its own self-sustaining chain reaction of fission events, each neutron generated by the accelerator would trigger a small cascade of additional neutrons in the subcritical reactor, yielding several bred atoms per initial neutron.

Based on this simple analysis, it is evident that electronuclear breeding of kilograms of plutonium-239 or uranium-233 for a fission bomb, or of grams of tritium for fusion boosting a bomb, would be technically challenging but nevertheless quite feasible for the wartime German program. It is important for historians to search for more evidence of such an electronuclear breeding program, both in archival documents and at locations that may have been involved in this work.

D. Chemical Reprocessing to Purify Bred Pu-239 or U-233

In nuclear power programs, chemical reprocessing of "spent" fuel that has been in a fission reactor is used to recover plutonium-239 that has been bred during the time in the reactor, as well as any leftover uranium-235 that was not burned up inside the reactor. Those fissionable fuel components can be repackaged and used again for reactor fuel; uranium-238 can also be recycled. Many other actinides in the fuel can be recycled without adversely affecting the repackaged reactor fuel. For nuclear weapons programs, the same techniques may be used to extract and concentrate the plutonium-239 from a uranium reactor (or from an electronuclear breeding particle accelerator) to make high-grade fuel for fission bombs.

Documents show that German scientists knew how to produce plutonium-239 from uranium-238 (p. 3794) and how to produce uranium-233 from thorium-232 (p. 3832), and knew that both of those fission fuels would be suitable for bombs. If one or more fission reactors were operational before the end of the war (p. 3794), or if accelerators were able to produce a significant amount of fission fuel (p. 3954), it seems likely that Germany would have developed and utilized chemical reprocessing methods to extract and purify the bred plutonium-239 or uranium-233. In fact, in the highly fragmentary documentation that is now available to scholars shows that there was in fact work to develop such reprocessing methods (p. 3826).

Although it is current unknown just how far that work may have progressed during the war, or in what geographic locations, the scientific details of reprocessing constrain where and how it could have been done, and may guide historians in locating relevant documents and geographic sites:

- Due to the relatively sophisticated chemistry involved in reprocessing and the fact that it would be tied to secret weapons development, it seems probable that any such reprocessing would have been run by I.G. Farben, or at the very least would have intimately involved I.G. Farben.

- Because of the large amount of spent uranium that would need to be processed for a much smaller amount of plutonium, and because of the great personal danger involved in exposure to the associated high levels of radiation and toxic chemicals, it moreover seems likely that any such work in wartime Germany would have involved slave labor (at least if it advanced beyond small-scale proof-of-concept laboratory experiments).

- Because of the large amount of material to be processed and the extreme danger in handling it, chemical reprocessing would probably have been conducted at or near the fission reactor(s) or electronuclear breeding site(s) where the plutonium was bred.

- For cooling of the fission reactor and for both cooling and chemical steps during reprocessing, a breeding/reprocessing facility would likely be located next to an abundant source of fresh water.

The most widely used chemical method for reprocessing spent fission fuel is called the PUREX (Plutonium Uranium Reduction EXtraction) process. Although it is quite complex [Benedict et al. 1981], a very simplified overview is illustrated schematically in Fig. D.1033. This description covers modern reprocessing for nuclear power programs, but a wartime weapons program would use very similar (or perhaps streamlined) steps:

1. Spent fuel rods are soaked in hot nitric acid, which dissolves uranium, plutonium, and fission products, but not zirconium alloy claddings and other hardware. Thus non-fuel reactor materials can be separated out for waste disposal. Gaseous fission products are also removed at this time.

2. Then the polar aqueous nitric acid solution containing uranium nitrates, plutonium nitrates, and fission-product nitrates is mixed with a nonpolar organic solvent, which is a kerosene-like mixture containing *n*-tributyl phosphate (TBP). At this point, uranium is in a hexavalent state (VI) and plutonium is in a tetravalent state (IV), both of which prefer to pass into the nonpolar TBP layer of the immiscible polar-nonpolar fluid combination. In contrast, the fission products are generally in a pentavalent state (V) and prefer to remain in the polar nitric acid layer, so they can be separated out, concentrated, and vitrified for disposal as high-level radioactive waste.

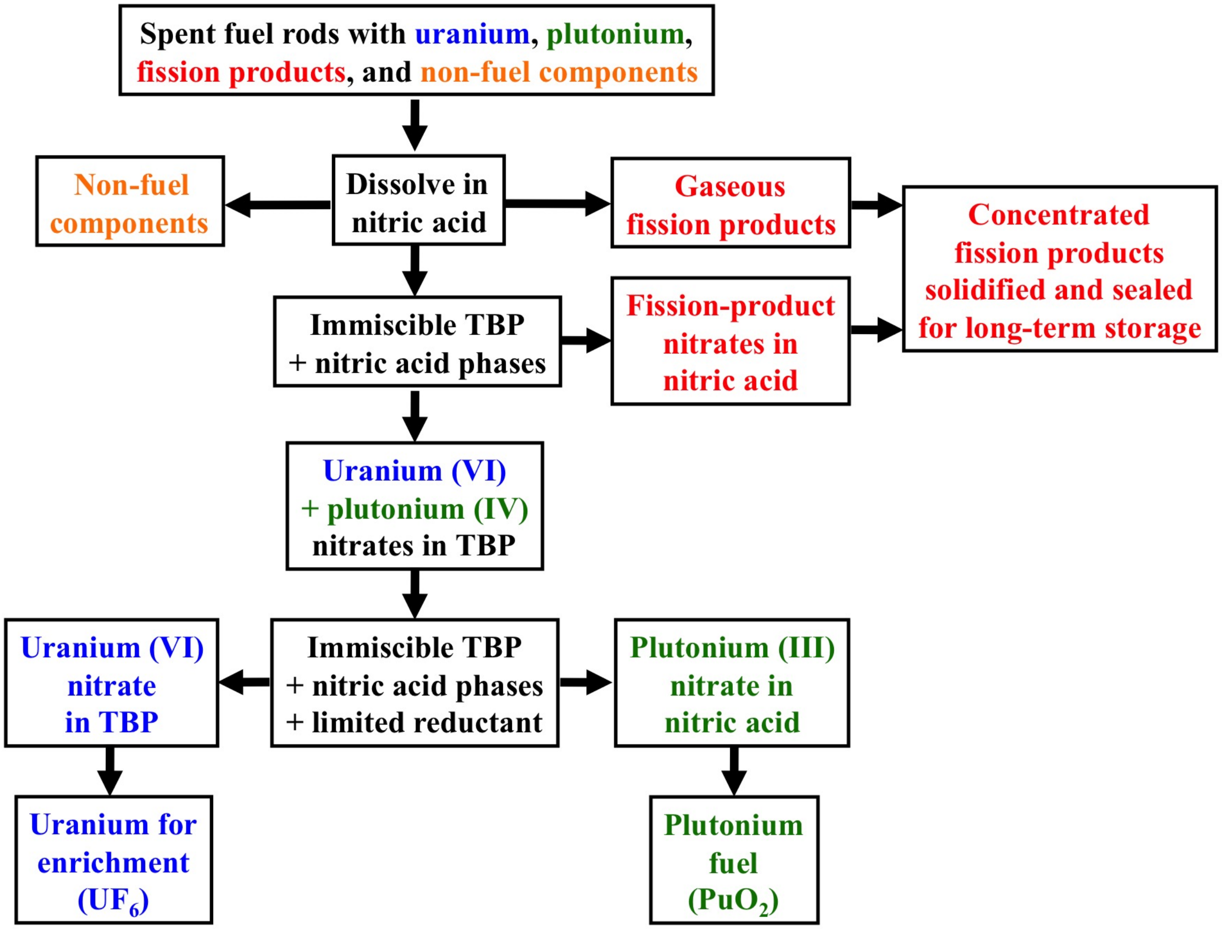
3. The TBP organic solution containing uranium and plutonium is treated with a limited reductant (such as ferrous ions, Fe^{+2}), which reduces plutonium (IV) to plutonium (III) but leaves the uranium (VI) unaffected. The nonpolar organic solvent is again mixed with polar aqueous nitric acid. The uranium (VI) still prefers the nonpolar solvent, but unlike plutonium (IV), plutonium (III) actually prefers the polar solvent. Thus plutonium and uranium can be separated for individual processing.

4. Uranium nitrate is purified from the nonpolar solvent and converted to uranium hexafluoride for enrichment if desired.

5. Plutonium nitrate is purified from the polar solvent and converted to plutonium dioxide for reactor fuel or plutonium metal for bombs.

In practice, up to three rounds of polar-nonpolar solvent purification are used to achieve high purity of the fission product, uranium, and plutonium fractions.

A similar reprocessing method used for separating thorium, uranium, and fission products from spent fuel in thorium-232/uranium-233 fuel cycles is called the Thorex process [Benedict et al. 1981]. By means of this process, one could supply a fission reactor or electronuclear breeding accelerator with natural thorium-232 and produce high-grade uranium-233 for fission bombs.



Spent fuel rods with uranium, plutonium, fission products, and non-fuel components
Non-fuel components

D.15.4 Analysis of Test Explosions from Primary Sources

While there are many potential metrics for the progress of the German nuclear program, the definitive litmus test would be a successful wartime nuclear weapons test. Of the alleged Baltic, Polish, and Thuringian test explosions described by the primary sources quoted earlier in this appendix, there is the largest amount of evidence for the Thuringian test, including numerous details that may be subjected to scientific analysis. Without discounting the other possible tests, the remainder of this discussion will focus on analyzing all of the currently available details about that March 1945 Thuringian test.

A. Primary Sources Used for the Analysis

Several of the primary sources provided general background information for the March 1945 Thuringian test. Wartime and postwar documents showed that within the top echelons of the SS, there was a prolonged and intense interest in developing a nuclear weapon, and an expectation around March 1945 that battlefield use of such a weapon was imminent. Likewise, wartime and postwar documents from Diebner, Schumann, Trinks, Guderley, and others confirmed that there were very active research programs on fission reactions, fission fuel production, fusion reactions, fusion fuel production, and spherical implosion bomb designs. How far those programs got, and whether or how they were combined together, is very unclear from the primary sources themselves, but perhaps answerable at least in part by modern theoretical and/or experimental analysis of the available data.

As summarized on p. 4480, at least ten primary sources specifically addressed the Thuringian test:

1-2. Ilyichev's November 1944 and March 1945 Soviet intelligence reports described the preparations for the Thuringian tests, the immediate consequences of the tests, and the detailed design of the nuclear device that was supposedly tested. The authenticity of the documents appears beyond doubt, since they are part of an extended paper trail that includes published responses by Kurchatov and Flerov, and that went all the way to Joseph Stalin. Furthermore, since the documents cast doubt on the Soviet Union's claim to be the second nuclear nation or to have achieved that status by its own scientific strength, there appears to be no incentive for Russians of any time period to have forged or embellished them. Likewise, these reports do not appear to have been a German attempt to bluff the Russians into believing that the Germans possessed a weapon that they did not actually have; a bluff would surely have claimed that the test explosion was much larger, and would not have handed the Russians a highly detailed and very effective design for a fission bomb. Of course, despite the authenticity of these documents, how accurate or inaccurate they may be depends on the competence of the unknown Soviet spy who transmitted the details from Germany.

3-4. Kurchatov's March 1945 letter and Flerov's two brief reports from May 1945 repeated many of the details from Ilyichev's second report, supporting the authenticity of that document. Most of their information was directly derived from Ilyichev's second report (which did not give a specific location for the nuclear test). However, the fact that by May 1945 Kurchatov and Flerov apparently knew of a specific location where they wanted to measure residual artificial radioactivity seems to indicate that they had received additional information not in Ilyichev's November 1944 and March 1945 reports.

5. Robert Döpel's testimony under interrogation by the Russians in 1946 confirms that there was an atomic bomb test on a German military base (such as those in Thuringia) before the end of the war. Unfortunately the only Russian interrogation summary that has been found thus far does not give any further details.

6-7. The testimonies of Werner and Wachsmut described the Thuringian test and its immediate aftermath. Although the 1962 East German transcript's chain of custody is uncertain and hence its authenticity is difficult to prove, the written testimonies by Werner and Wachsmut are consistent with oral testimonies that they each gave later in life, consistent with each other, consistent with details from the other sources that reported the Thuringian test, and consistent in appearance with other East German interrogation transcripts from that place and time. As will be shown, they are also highly consistent with the physics of nuclear weapons, in ways that would not have been possible for Werner and Wachsmut, their interrogators, or a document forger to foresee. Therefore, the testimonies of Werner and Wachsmut will be included in the discussion here with appropriate caution. These two testimonies are the only sources that named a specific location for the Thuringian test, but otherwise the basic facts of the Thuringian test do not depend upon their testimonies.

8. The 1966 East German reports on the interrogation of Erich Rundnagel appear to be authentic and were confirmed by Rundnagel's nephew. Although Rundnagel did not address the actual test, he gave details that seem relevant to the bomb design and preparations.

9. Oscar Koch's 1960s description of a high-level 1945 U.S. intelligence report appears as credible as the Soviet intelligence report. Although it gave fewer details than Ilyichev's reports, those that it did contain are highly consistent with those given by Ilyichev. The most puzzling aspect is that Koch stated that U.S. aerial surveillance photos did not show the blast damage that had been reported in the test area. Some plausible explanations are (a) that the Germans quickly replanted, restored, cleaned, or camouflaged the affected area, (b) that the aerial surveillance photos were not of the correct location, and/or (c) that the Americans were looking for much larger-scale blast damage than the Thuringian test actually produced.

10. The interviews with Grothmann described many details about the Thuringian test, its background, and its aftermath. Major caveats are that the interviews were conducted in private, that they were held 55–57 years after the events in question, and that tapes of the interviews were erased. Nonetheless, historians have been able to independently confirm a large number of obscure details covered in the interviews [Karlsch and Petermann 2007, p. 29; Karlsch 2006; Nagel 2011, p. 64], and scientific details from the interviews are very consistent with known physics and engineering principles, even though Grothmann was not a scientist or engineer. Grothmann provided information that is in excellent agreement with Ilyichev's reports, which were discovered in a Moscow archive only after Grothmann had already died, and Grothmann's statements agree with other sources about the secret wartime programs that have only emerged in recent years. For a more extensive discussion of the reliability of this source, see pp. 3396–3397.

As shown on p. 4480, there is remarkably good agreement among these ten primary sources about the details of the test date, location, organizations or people who were involved, blast, radioactivity, resulting casualties, and device design. Those details will next be used as the basis for preliminary theoretical estimates of the explosive yield, radioactive release, and device design parameters.

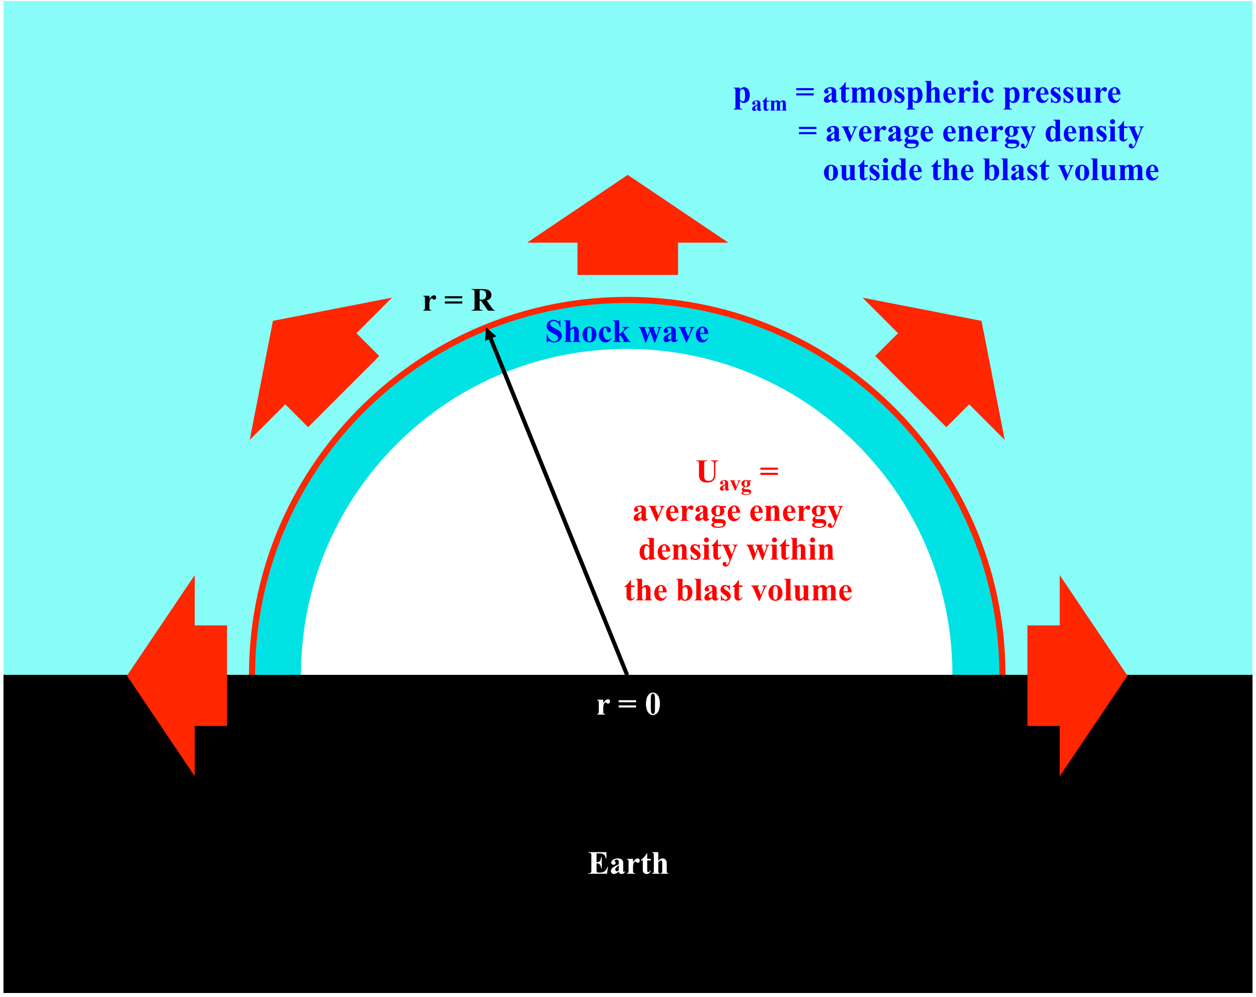
Figure D.740 is a map of the Ohrdruf and Arnstadt area that was possibly involved in the March 1945 test. In Fig. D.741, colored lines illustrate clues to the location of the test as described by Werner and Wachsmut. These clues include the approximate boundary of the military base (green), population centers with possible sickness from radioactive fallout (red), the direction in which Werner reported seeing the explosion (yellow), driving distances for Wachsmut from the Ringhofen estate (blue), and the location of an apparent crater on aerial photos from pp. 4541–4545 (purple). Note that those clues place the test roughly in the center of the Ohrdruf military base, which would also make sense from a security perspective.

If information from Werner and Wachsmut is excluded from the analysis, the key facts and data regarding the nuclear test remain the same, except the exact location in Thuringia is then unknown. Based solely on the other sources, the test might have occurred on the Ohrdruf military base, or it might have occurred in some other remote wooded location in Thuringia that could be tightly secured by the SS (likely a military base).

B. Estimating Explosive Yield from Primary Sources

Simple estimates of the relationship between the energy released in an explosion and the radius of damage caused by that explosion can easily be made from first principles. The explosion will be assumed to release an energy E at a point source at radial position $r = 0$ at or very near the surface of the earth, surrounded by atmosphere of initial pressure p_{atm}, as shown in Fig. D.1034. For reference, one ton of TNT high explosive is defined to produce an energy of 4.184×10^9 Joules (J) (although the actual yield from real TNT can vary somewhat around this value). The energy of the explosion will be distributed throughout a hemispherical volume of ever-expanding radius R, where the surface at $r = R$ is a shock wave propagating outward into the atmosphere. Using the volume $(2/3)\pi R^3$ of the hemisphere and defining the average energy density deposited within the hemispherical volume as U_{avg}, the explosive energy yield may be written as

$$E = \frac{2}{3}\pi R^3 U_{\text{avg}} \tag{D.46}$$



p_{atm} = atmospheric pressure
= average energy density
outside the blast volume
r = R
Shock wave
U_{avg} =
average energy
density within
the blast volume
r = 0
Earth

Figure D.1034: Hemispherical shock wave expanding from an initial point on the earth's surface.

Since the total energy E is constant (neglecting any losses), the average energy density U_{avg} of the explosion will decrease as the explosion radius R increases with time. The explosion will be the dominant force in the local environment until its average energy density drops below the pressure-derived potential energy density of normal atmospheric pressure, $p_{\text{atm}} \approx 1.01 \times 10^5$ Pascals (Pa=J/m^3) (using the sea-level average pressure). Of course, the shock wave at the expanding surface contains more energy density than the volume-averaged value, and the explosive energy density can do serious damage to buildings, trees, and people even when it is only a fraction of normal atmospheric pressure.

If one assumes that the explosion will do major damage until the average energy density drops to $U_{\text{avg}} \approx p_{\text{atm}}/10$ at some blast radius $R = R_{\text{blast}}$, the energy from Eq. (D.46) may be written as:

$$\begin{aligned} E_{\max} &\approx \frac{2}{3}\pi R_{\text{blast}}^3 \frac{p_{\text{atm}}}{10} = \left(\frac{2\pi \cdot 1.01 \times 10^5 \text{ J/m}^3}{3 \cdot 10 \cdot 4.184 \times 10^9 \text{ J/ton}} \right) R_{\text{blast}}^3 \\ &\approx \left(\frac{R_{\text{blast}}}{58.3 \text{ meters}} \right)^3 \text{ tons}\,, \end{aligned} \tag{D.47}$$

in which Eq. (D.47) expresses the explosive energy yield in equivalent tons of TNT.

On the other hand, if one assumes that the explosion will do significant damage until the average energy density drops much further to $U_{\text{avg}} \approx p_{\text{atm}}/100$ at some blast radius $R = R_{\text{blast}}$, the explosive yield from Eq. (D.46) may be written as:

$$\begin{aligned} E_{\min} &\approx \frac{2}{3}\pi R_{\text{blast}}^3 \frac{p_{\text{atm}}}{100} = \left(\frac{2\pi \cdot 1.01 \times 10^5 \text{ J/m}^3}{3 \cdot 100 \cdot 4.184 \times 10^9 \text{ J/ton}} \right) R_{\text{blast}}^3 \\ &\approx \left(\frac{R_{\text{blast}}}{126 \text{ meters}} \right)^3 \text{ tons} \end{aligned} \tag{D.48}$$

For a given measured blast radius, the released explosive energy could vary somewhere between the minimum value given by Eq. (D.48) and the maximum value given by Eq. (D.47), depending on how resistant to blast damage the surround area is, deviations of the actual terrain from the assumed perfectly flat surface, and other factors. Note that Eq. (D.47) gives a maximum energy 10 times larger than the minimum energy of Eq. (D.48), since its assumed energy density is 10 times larger ($p_{\text{atm}}/10$ vs. $p_{\text{atm}}/100$). Within that range, a good single value for a ballpark approximation would be the geometric mean, found by using Eq. (D.46) with $U_{\text{avg}} \approx p_{\text{atm}}/(10\sqrt{10})$:

$$\begin{aligned} E_{\text{geo mean}} &\approx \frac{2}{3}\pi R_{\text{blast}}^3 \frac{p_{\text{atm}}}{10\sqrt{10}} = \left(\frac{2\pi \cdot 1.01 \times 10^5 \text{ J/m}^3}{3 \cdot 10\sqrt{10} \cdot 4.184 \times 10^9 \text{ J/ton}} \right) R_{\text{blast}}^3 \\ &\approx \left(\frac{R_{\text{blast}}}{85.5 \text{ meters}} \right)^3 \text{ tons} \end{aligned} \tag{D.49}$$

Cold-War-era U.S. books tended to specify blast waves in terms of the pounds per square inch (psi) of peak overpressure in the shock wave. Converted into those terms, Eq. (D.49) for the geometric mean of the explosive energy would give the blast radius for 5.1 psi (35 kPa) of peak overpressure, which is generally considered enough to demolish trees or wood-frame buildings. Likewise, Eq. (D.47) for the maximum case would correspond to a peak overpressure of 9.1 psi (63 kPa, enough to damage or destroy even reinforced buildings), and Eq. (D.48) for the minimum case would correspond to a peak overpressure of 2.9 psi (20 kPa, enough to damage but perhaps not demolish trees or wood-frame buildings). Thus the equations derived here are highly consistent with the standard empirical equations from Cold War atmospheric nuclear tests, and Eq. (D.49) in particular should be a good guide for the level of destruction mentioned by Ilyichev.

Ilyichev described the blast radius as $R_{\text{blast}} = 500\text{–}600$ meters. Using Eqs. (D.47)–(D.49), a blast radius of $R_{\text{blast}} = 500$ meters corresponds to an explosive energy somewhere in the range $E = 63\text{–}630$ tons, with a geometric mean of 200 tons. Likewise, the larger blast radius $R_{\text{blast}} = 600$ meters corresponds to an explosive energy somewhere in the range $E = 110\text{–}1100$ tons, with a geometric mean of 350 tons. These values are consistent with previous estimates based on the same data [Eilers 2007, 2015; Mineev and Funtikov 2007].

Ilyichev also described the bomb as having a total weight of approximately 2 tons and being filled largely with TNT. If such a bomb had exploded in a conventional, non-nuclear manner, its explosive energy would therefore be only ~ 2 tons. The absolute minimum explosive energy consistent with the reported blast radius is 30 times larger than that value, and the actual energy may well have been several hundred times greater than the non-nuclear yield of TNT alone. Thus some sort of nuclear explosion appears to be the only satisfactory explanation for the reported blast size.

An independent method of estimating the explosive energy would be to use the dimensions of the crater it created in the ground. Unfortunately, if the bomb had an explosive energy less than 1000 tons and was mounted on a tower for the test (to facilitate diagnostics, as in the first U.S. fission bomb test in New Mexico on 16 July 1945, and as described by Schumann and Grothmann), it would likely not leave a significant crater [Glasstone and Dolan 1977, p. 255]. If the aerial reconnaissance photos on pp. 4541–4545 do indeed show the correct location of the test, the suggestive ejecta pattern that is visible in the 21 March 1945 and 9 June 1945 aerial reconnaissance photos may have been the only physical trace of the blast, apart from radioisotopes.

C. Estimating Radioactive Release from Primary Sources

In addition to the reported blast radius, the reports of radioactive effects or radiation sickness by Ilyichev, Grothmann, Werner, and Wachsmut seem to suggest some sort of nuclear explosion. In theory, a nuclear explosion could be due to fission reactions alone, fusion reactions alone, or some combination of fission and fusion reactions. In the 75+ years since 1945, scientists have been unable to create a net-energy-producing pure fusion reaction without the assistance of fission reactions [Gsponer and Hurni 2009, pp. 139–141; Winterberg 2010, pp. 297–298, 302], so the possibility that the described 1945 test was a pure fusion weapon seems too remote to consider. Both pure fission and fission-fusion hybrid designs are quite possible however. Even for plausible fission-fusion hybrid weapon designs, the fraction of released energy that comes from fusion reactions is negligible. Therefore the explosive energy yield (calculated from the reported blast radius) may be used to find the amount of fission fuel consumed and hence the amount of radioactive fallout.

Fission fuel consumed

By definition, one mole (6.022×10^{23}) of uranium-235 atoms has a total mass of 235 grams. Upon fission, each atom releases approximately 180 million electron-volts (eV) of energy (not counting energy lost as neutrinos, or energy released in delayed radioactivity), which can be converted into Joules or equivalent tons of TNT energy by the conversion factors 1.602×10^{-19} J/eV and 4.184×10^{9} J/ton. Putting all of this information together, the number of grams of U-235 that must be completely fissioned to produce one ton TNT equivalent of explosive energy is:

$$\frac{(235\text{ g})\ (4.184 \times 10^{9}\text{ J/ton})}{(6.022 \times 10^{23})\ (180 \times 10^{6}\text{ eV})\ (1.602 \times 10^{-19}\text{ J/eV})} \quad \approx \quad 0.0566\ \frac{\text{grams}}{\text{ton}} \tag{D.50}$$

Ilyichev specifically said the device used U-235 as fission fuel. In principle, other fission fuels could have been used: uranium-233 (U-233, created by bombarding natural thorium-232 with neutrons), neptunium-237 (Np-237, e.g., created by knocking a neutron out of natural uranium-238), or plutonium-239 (Pu-239, creating by bombarding natural uranium-238 with neutrons). Energy values for those other fission fuels are approximately the same as that for U-235, so Eq. (D.50) can safely be used as the basis for any fission calculations.

For explosive yields in the range of 63–1100 tons with a geometric mean of 200–350 tons, as calculated in Section D.15.4, the mass of fuel completely fissioned is:

$$M_{\text{fissioned}} \quad = \quad 3.6\text{–}62\text{ grams, with a geometric mean of }11.3\text{–}19.8\text{ grams.} \tag{D.51}$$

Thus the best ballpark guess is that the reported explosion would have completely fissioned $\sim$ 10–20 grams of uranium. This is a very small quantity considering that nuclear weapons would normally have many kilograms of fission fuel, but Grothmann reported that only a very small amount of fuel was used in this test device, and that larger amounts of fuel were ready to be used in subsequent devices. For a small test, the total amount of fissionable fuel might have been as little $\sim$100 grams, which is very consistent with the result in Eq. (D.51), since only some fraction of the fuel would have time to fission during the very brief time that the core of the bomb was maximally compressed.

Initial radiation from the explosion

People who were very close to the test site would have been exposed to the initial radiation (gamma, neutrons, and beta) released during the actual explosion. For a fission explosion of 200–350 tons, the lethality (10 Grays or 1000 rads) radius for this prompt radiation is $\sim$ 500 meters, very comparable to the blast radius [Glasstone and Dolan 1977, p. 333]. Thus anyone present on the field where the device was tested would have been either killed immediately or left injured and dying from the blast, radiation, and heat. This is highly consistent with the reports of Ilyichev, Grothmann, Werner, and Wachsmut.

If the blast radius was 500–600 meters as reported by Ilyichev, Wachsmut's estimate of 700 bodies was correct, and those victims had been uniformly spread out within an area $\pi R^2 \ \sim$ 785,000–1,130,000 m^2 around the device when it was tested, the spacing would have been

$$\sim 1100\text{–}1600\ \mathrm{m}^2 \text{ per person on average} \tag{D.52}$$

or

$$\sim 33\text{–}40\ \mathrm{m} \text{ between people if uniformly spread out} \tag{D.53}$$

Thus 700 people could have easily fit within the blast radius, even if they were spread out. It seems highly unlikely that the detonation would have been accidentally triggered at an unexpected time before people had had time to take cover. A far more plausible explanation is that the SS scattered POWs around the test area to serve as human guinea pigs to measure the effects at varying distances from the explosion.

Indeed, Ilyichev's report appears to suggest that the SS made detailed correlations of prisoners' positions before the explosion and their conditions after the explosion (p. 4485): "Prisoners of war who were near the epicenter of the explosion died, often without leaving a trace. Prisoners of war who were in the area beyond the center of the explosion have burns on their face and body, the strength of which depends on their position in relation to the epicenter of the explosion."

It is well documented that POWs were used as human test subjects for new nerve agents [Tucker 2006, p. 51] and for new biological weapons.[32] Thus the allegations made separately by Ilyichev and Wachsmut are highly consistent with what is known to have taken place in other Third Reich programs to develop weapons of mass destruction.

In fact, if the statements of Grothmann and Wachsmut are correct, the large size of the explosion and the large number of casualties for the very small amount of fission fuel used apparently surprised even the SS.

---

[32] Barenblatt 2004; Blome 1941; Michael Carroll 2004; Deichmann 1996; Geißler 1998a, 1998b; Gold 1997; Haagen 1941; Friedrich Hansen 1993; Sheldon Harris 2002; Kater 1989; Keremidis 2013; Klee 2001; Leitenberg and Zilinskas 2012; Posner and Ware 2000; Regis 1999; Reinhardt 2013; Vivien Spitz 2005; Tokyo War Crimes Trial 1950; U.S. Army 1956.

Radioactive fallout from the explosion

From the explosive yield and amount of fuel fissioned, one can also calculate the amount of radioactive fallout. The radioactive fallout decays rapidly, emitting 80% of its total radiation within the first 24 hours, and gradually emitting the remaining 20% over the following days, months, and years [Glasstone and Dolan 1977, p. 397]. Radioactive fallout from a 1 kiloton fission explosion, spread uniformly over a flat area of 1 square mile, would cause a radiation exposure 3 feet above the ground (the approximate center of an adult human) of 2900 rads per hour 1 hour after the explosion, or 21,750 rads total within the first 24 hours after the explosion [Glasstone and Dolan 1977, pp. 390, 395—24 hour cumulative dose is dose rate at 1 hour multiplied by 7.5 hours due to decay]. Converting that information from kilotons to tons, from square miles to km^2, and from rads to Grays (Gy, where 1 Gy=100 rads), one finds:

$$1\ \frac{\text{ton}}{\text{km}^2} \implies 0.0751\ \frac{\text{Gy}}{\text{hr}}\ \text{at 1 hour averaged over area} \tag{D.54}$$

$$\implies 0.563\ \text{Gy within 24 hours averaged over area} \tag{D.55}$$

As calculated in Section D.15.4, the explosive yield had a geometric mean of 200–350 tons. The area over which the corresponding amount of fallout would be distributed could vary significantly depending on local winds and topography, but a plausible ballpark estimate for the affected region might be a $\sim$ 10 km $\times \sim$ 10 km area, or $\sim$ 100 km^2. Taken together, those estimates give an average of 2–3.5 tons/km^2, and Eqs. (D.54)–(D.55) can be scaled accordingly:

$$2\text{–}3.5\ \frac{\text{tons}}{\text{km}^2} \implies 0.150\text{–}0.263\ \frac{\text{Gy}}{\text{hr}}\ \text{at 1 hour averaged over area} \tag{D.56}$$

$$\implies 1.13\text{–}1.97\ \text{Gy within 24 hours averaged over area} \tag{D.57}$$

Gamma and beta radiation emitted by fission products in the fallout would begin to produce noticeable symptoms of radiation sickness after a cumulative exposure of $\sim$ 1 Gy, very serious illness at $\sim$ 2 Gy, and fairly consistent lethality (within hours or days after exposure) at $\sim$ 10 Gy [Glasstone and Dolan 1977, pp. 575–587, using 1 rad $\approx$ 1 rem or 1 Gray $\approx$ 1 Sievert for gamma, beta, and neutrons]. Thus the expected average dose from Eq. (D.57) falls perfectly within that 1–2 Gy window for noticeable but readily survivable radiation sickness.

Ilyichev reported that most the civilian population in the surrounding area had been evacuated. Someone who remained in the surrounding area (within the $\sim$ 100 km^2 general area but not at the test site), and who was exposed to the fallout with the first day or so after the test by being outside or consuming water or food that had been outside, might have experienced mild symptoms of radiation sickness that would have resolved themselves within a matter of days. People who remained in the surrounding area but did not have much exposure to the fallout may not have had any noticeable symptoms.

In the area immediately around the test site, the radioactive fallout and dosage would be significantly higher than in the larger surrounding region. Just how much higher would again depend on the local winds and topography, and also on the relative sizes of the areas in question. Data from a number of U.S. nuclear tests suggests that the fallout dosage immediately around a test site is $\sim$ 10–100 times higher than that in the much larger surrounding area that receives significant fallout, with a geometric mean value of $\sim$ 30 times higher [Glasstone and Dolan 1977, pp. 419–439]. Using that mean value to multiply Eqs. (D.56)–(D.57), ballpark values for the radiation dose at the Thuringia test site would be:

$$4.50\text{–}7.89\ \frac{\text{Gy}}{\text{hr}} \qquad \text{at 1 hour at test site} \tag{D.58}$$

$$33.9\text{–}59.1\ \text{Gy} \qquad \text{within 24 hours at test site} \tag{D.59}$$

As mentioned, those estimates use the estimated geometric mean from the fallout patterns, and the actual values might have been between $\sim$ 3 times smaller and $\sim$ 3 times larger than the results in Eqs. (D.58)–(D.59). Since a cumulative dose of $\sim$ 10 Gy will cause fairly consistent lethality within hours or days after exposure, even a person who was fully protected from the initial radiation, heat, and blast of the explosion but then visited the test site in the hours after the explosion could rapidly acquire a lethal dose. This factor may help account in part for the lack of later witnesses.

Based on the above analysis (which was derived only from the known physics of fission explosions and Ilyichev's statement that the blast radius was 500–600 meters), the explosion's prompt radiation at the test site, the radioactive fallout at the test site within the first 24 hours, and the radioactive fallout in nearby towns within 24 hours would easily fit Ilyichev's description that a "massive radioactive effect was observed."

Comparison of theoretical results with numerical estimates based on the statements of Werner and Wachsmut

Although the chain of custody and historical authenticity of the written testimonies by Werner and Wachsmut cannot be verified, those testimonies made several specific claims that can actually be tested numerically against the preceding physics calculations.

Werner and Wachsmut (and also Grothmann) reported symptoms of what sounded like radiation sickness among the populations of towns near the test site. Werner specifically listed the towns in which she said people had reported those symptoms, and they are indicated by red circles on p. 4563. The purple circle in that figure is the suspected location of the explosion. Note that the affected towns generally range from north to east of the explosion, which is plausible if the local winds were blowing from the southwest at the time of the test. Based on the distribution of affected towns around the test site, a reasonable estimate for the affected region is a $\sim 100\ \mathrm{km}^2$ area. (For reference, the outermost blue circle in Fig. D.741 has a diameter of 10 km.)

Noticeable but readily survivable radiation sickness in that area within a day after the test, as reported by Werner and Wachsmut (and also Grothmann), suggests an average dose of

$$1\text{–}2\ \ \mathrm{Gy}\ \ \text{within 24 hours averaged over area of} \sim 100\ \mathrm{km}^2 \tag{D.60}$$

Thus the area-averaged dose in Eq. (D.60), which was derived from the testimonies of Werner and Wachsmut, agrees extremely well with the prediction from Eq. (D.57), which was derived from Ilyichev's report and the physics of fission explosions.

A completely independent estimate of the radioactivity at the test site may also be derived from the testimony of Werner and Wachsmut. Werner stated that the test occurred at 9:30 p.m. on 4 March and that a large SS group came by at 2:00 p.m. on 5 March on their way to dispose of the bodies. Wachsmut testified that he worked to burn bodies at the test site from sometime in the afternoon until sometime before 11:00 p.m. on 5 March, with a break of unstated length in the middle for decontamination at the Ringhofen estate some distance away. Wachsmut also stated that he and his fellow workers were unable to eat for at least a couple of days afterward, which suggests moderate radiation sickness in the $\sim$ 1–2 Gy cumulative dose range. (An alternative interpretation is that the inability to eat for days was simply a psychological reaction to what they witnessed. That explanation is possible, but seems insufficient to account for the symptoms as Wachsmut stated he and his fellow workers were already very experienced at disposing of badly tortured prisoners' bodies, and that the inability to eat affected all of his work crew.)

To take nice round numbers as a very simple approximation, one could assume that Wachsmut was exposed to the fallout at the test site from $\sim$ 3:30 p.m. until $\sim$ 9:30 p.m. on 5 March, or in other words from 18 to 24 hours after the test. The cumulative dose from fallout between 18 and 24 hours after an explosion is equal to the dose rate 1 hour after the explosion multiplied by approximately 0.25 hours [Glasstone and Dolan 1977, p. 395, 7.5 hours - 7.25 hours = 0.25 hours for the multiplier]. Thus if Wachsmut received 1–2 Gy between 18 and 24 hours at the test site, the dose rate at the test site 1 hour after the explosion would have been

$$\frac{1\text{–}2\ \text{Gy}}{0.25\ \text{hr}} = 4\text{–}8\ \frac{\text{Gy}}{\text{hr}} \qquad \text{at 1 hour at test site} \qquad \text{or} \tag{D.61}$$

$$30\text{–}60\ \text{Gy} \qquad \text{within 24 hours at test site} \tag{D.62}$$

Therefore Eq. (D.61)'s completely independent estimate of the dose rate at the test site immediately after the test, derived from the testimonies of Werner and Wachsmut, agrees extremely well with the prediction from Eq. (D.58), which came from Ilyichev's report and the physics of fission explosions. The corresponding cumulative dose rate at the test site for the first 24 hours is given by Eq. (D.62), which may be compared with Eq. (D.59).

Furthermore, one should note that Werner and Wachsmut's statements suggest that the fallout dose at the test site, given by Eq. (D.62), was ~ 30 times larger than the average fallout dose received by the larger community, given by Eq. (D.60). That is in excellent agreement with typical fallout patterns for nuclear weapons [Glasstone and Dolan 1977, pp. 419–439], and is quite remarkable considering that this ratio was derived purely from unrelated details given in Werner and Wachsmut's statements.

In making these numerical assessments of details from the written statements of Werner and Wachsmut, one should bear in mind several very important caveats:

- These equations are simply **ballpark estimates** for the average exposure, based in turn on both a ballpark estimate for the explosive yield and also a ballpark estimate for the size of the affected region, so the actual average exposure could have been significantly higher or lower.

- The relative distribution of fallout at the test site and in the larger surrounding area would depend greatly on the local winds and geography, so again these are simply ballpark estimates.

- Since the numerical results derived from Ilyichev's report are ballpark estimates, and those derived from the statements of Werner and Wachsmut are ballpark estimates, at best one can say that the agreement between those two independently derived sets of numerical results is simply in the right ballpark. The fact that the numbers happened to be so similar is not of any physical significance, beyond confirming that the independent ballparks overlap well.

- This physics analysis cannot address whether the written statements of Werner and Wachsmut are authentic, or whether they might have been forged or altered. This analysis can only conclude that the statements of Werner and Wachsmut are highly consistent with the known physics of nuclear weapons, and with physics estimates derived from Ilyichev's report, which was not released until after the written statements of Werner and Wachsmut had already been published.

Expected radioisotopes after 75+ years

After 75+ years, the radioactivity of the fallout would have dropped to $\sim 2\times10^{-9}$ of its radioactivity 1 hour after the explosion [Glasstone and Dolan 1977, p. 393]. Using Eqs. (D.56) and (D.58) with this information, the residual radioactivity would be

$$\text{Averaged over area:} \quad 3.0\text{–}5.3 \times 10^{-10} \ \frac{\text{Gy}}{\text{hr}} \ \text{at 75 years} \tag{D.63}$$

$$2.6\text{–}4.6 \times 10^{-6} \ \frac{\text{Gy}}{\text{yr}} \ \text{at 75 years} \tag{D.64}$$

$$\text{At test site:} \quad 8\text{–}16 \times 10^{-9} \ \frac{\text{Gy}}{\text{hr}} \ \text{at 75 years} \tag{D.65}$$

$$7\text{–}14 \times 10^{-5} \ \frac{\text{Gy}}{\text{yr}} \ \text{at 75 years} \tag{D.66}$$

Since typical radioactive background from terrestrial, solar, and cosmic sources is at least $1\text{–}2\times10^{-3}$ Gy/yr, the residual radioactivity at the test site would be at least ~ 10–30 times smaller than the natural background and hence extremely difficult to detect.

Put differently, the estimated initial values that went into calculating this final value of the residual radioactivity would have to be off by a factor of ~ 10–30 times, and in the right direction, in order for the residual radioactivity to be detectable above the natural background level. For that to have been the case, the explosive yield would have to have been ~ 10–30 times larger than was estimated here, or ~ 2–10 kilotons, which seems highly unlikely given the descriptions of the test, and also the German military's logical desire to minimize the fission fuel consumed and the radioactivity produced on German soil by the test. Alternatively, for the residual radioactivity to be detectable with the explosive yield estimated here, the fallout would have to have been confined to an area ~ 10–30 times smaller than has been assumed here, which also seems highly unlikely. In fact, after 75+ years of water, wind, and human activity, the fallout could easily have become scattered over a significantly larger area than the initial area assumed here, and/or become buried to varying depths in the ground, making it even harder to detect than has been calculated here. As discussed above, the radioactivity in the larger surrounding area would be even lower than that at the test site, by a factor of ~ 10–100.

From fundamental physics, one must therefore conclude that measurements of residual radioactivity cannot be used to try to prove or disprove whether the March 1945 Thuringian nuclear test occurred. This same conclusion, for the same reasons, also applies to the Baltic, Polish, or any other possible wartime German nuclear tests.

Nonetheless, it is possible that methods other than radiation sensors might be used to detect residual products left by the test. For that approach to have some chance of success, the residual products should be (a) unique to the nuclear test, and (b) present in the largest quantities possible. The first criterion rules out common explosives such as TNT and RDX, as well as common metals such as aluminum and iron, that presumably would have made up large fractions of the nuclear device, but that could also have been left by conventional weapons that have been stored, tested, or used at that location for more than a century.

In addition to the radioactive fallout from fission products, any unfissioned uranium would be scattered by the explosion. If only ∼ 100 g U-235 was used (and only a faction of that was fissioned) and was surrounded by only non-uranium materials (gold, tungsten, rhenium, etc.) in the device, as little as ∼ 100 g of unfissioned uranium may have been scattered. On the other hand, if the device used a ∼ 100 kg natural uranium tamper as was reportedly used in the 1945 U.S. Gadget and Fat Man implosion bombs, as much as ∼ 100 kg of unfissioned uranium may have been scattered. Again assuming that the explosion and winds initially scattered the fallout over a ∼ 100 km^2 area, the expected amount of unfissioned uranium could be anywhere in the range:

$$\sim 1\text{ g} - 1\text{ kg of unfissioned uranium per km}^2\text{, or} \tag{D.67}$$

$$\sim 10^{-6} - 10^{-3}\text{ g of unfissioned uranium per m}^2 \tag{D.68}$$

As with the other explosion products, that is only the expected initial amount in 1945. After 75+ years, any unfissioned uranium could have become spread over a much larger area and/or seeped down into the ground, so the current amount could be far lower than this initial estimate.

Thus the residual radioactivity from a 1945 nuclear test of the magnitude described would now be far smaller than the average natural background radiation and therefore undetectable. Nonetheless, it might be possible to detect fission products or unfissioned fuel from the test by analyzing soil samples via mass spectrometry, particle-induced X-ray emission, neutron activation analysis, or other highly sensitive methods. Unfortunately, even these methods might have difficulty distinguishing the small amount of remaining telltale products from a background that would include not only naturally occurring isotopes but also fallout from the 1986 Chernobyl fission reactor accident and contamination from decades of Cold War military exercises (including both nuclear materials and depleted-uranium conventional projectiles).

Uranium-235 tends to fission into a light fragment with mass number $A_1 \sim 95$ and a heavy fragment with $A_2 \sim 140$. The sizes of the resulting light and heavy fragments vary somewhat, creating a double-peaked mass distribution [Fig. D.1035(a)]. Fig. D.1035(b) shows that for different masses of the fissioning nucleus, the heavy fragment mass peak remains essentially fixed, while the light peak is left to shift with the changes in total mass. If there is very little energy initially put into the fission reaction, the trough between the light and heavy mass peaks is quite deep. Yet as the input energy increases, the trough becomes less and less deep [Fig D.1035(c)]; the fissioning nucleus becomes able to fall into almost any final state, not just the energetically lowest ones.

In general, fission products are inherently β emitters due to their excess of neutrons inherited from the massive original nucleus, with some γ emission as well. Most fission products have half-lives less than a couple of years or so and thus will largely decay to more stable isotopes within a few years. Of the vast array of fission products, only a handful do not decay within a few years; these are listed in Table D.11 [using data drawn from Benedict et al. 1981]. (Note that actinides are not included.)

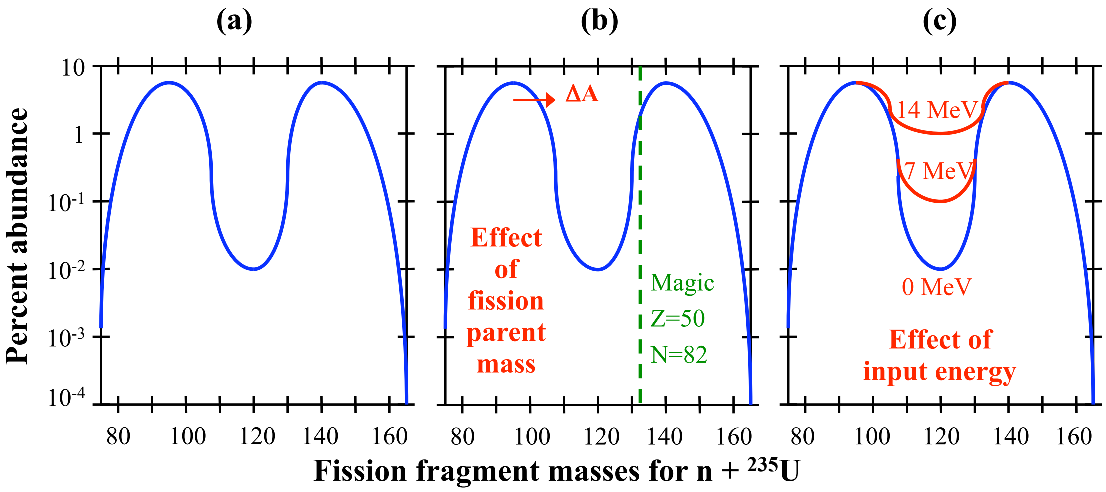


Figure D.1035: Mass distributions of nuclear fragments resulting from fission. (a) Low-energy neutron-induced fission of ^{235}U. (b) Effect of increasing the initial mass of the nucleus undergoing fission by ΔA. (c) Effect of input energy on neutron-induced ^{235}U fission.

Nuclide	**Half-life (years)**
Europium-154	16
Strontium-90	29
Cesium-137	30
Samarium-151	87
Technetium-99	2.1×10^5
Selenium-79	1.1×10^6
Zirconium-93	1.5×10^6
Cesium-135	2.3×10^6
Iodine-129	1.6×10^7

Table D.11: Major long-lived radioactive fission products.

Despite background contamination and the passage of time, the use of three approaches in combination might be able to provide good evidence of a wartime German nuclear weapons test:

1. Ion mass spectrometry, particle-induced X-ray emission, neutron activation analysis, or other highly sensitive methods could detect very low levels of fission products, even non-radioactive fission products or other bomb components, and identify not just elements but specific isotopes and their relative concentrations.

2. Analyzing numerous samples from suspected test sites as well as surrounding regions could determine what background levels of which isotopes are present (from Chernobyl, Cold War military programs, or natural sources), and how much variation there is in those background levels. If multiple samples from a suspected test site contain fission products that generally agree with each other but are well outside the range expected of background contamination, that finding would be of great interest.

3. From Fig. D.1035, the relative quantities of different fission products depend on whether they came from highly enriched U-235, low-enriched reactor-grade U-235, Pu-239, or U-233. The relative quantities also depend on the neutron energies used in the fission reactions—fast neutrons for weapons and slow neutrons for reactors (although could there have been significant fast fission during the Chernobyl event?). Thus the relative quantities of various isotopes in the sample could indicate the specific type of fission fuel and fission reactions from which they originated. However, there may not be enough fission products to detect (for a 200-ton explosion, $\sim$ 10 grams of fission products scattered over the area). In that case, the most promising component to detect would be the tamper (likely $\sim$ 100 kg of mostly U-238 scattered over the area), if that could be distinguished from U-238 background contamination.

D.15.5 Estimating Device Design Parameters from Primary Sources

Very tentative design parameters for the device that may have been tested in Thuringia in March 1945 may be estimated from the primary sources, simple physics, and unclassified documents about the United States' first implosion bombs (Gadget, shown in Fig. D.1036, that was detonated in New Mexico on 16 July 1945, and its fully packaged version, Fat Man, shown in Fig. D.1037, that was dropped on Nagasaki on 9 August 1945) and other nuclear weapon designs [Coster-Mullen 2012; Goncharov 1996a, 1996b; Goncharov and Riabev 2001; Gsponer and Hurni 2009; Chuck Hansen 1988, 2007; Bruce Cameron Reed 2015a, 2019; Rhodes 1986, 1995; Serber 1992; Smyth 1945; Sublette 2019; Wellerstein and Geist 2017; Winterberg 2010].

Of the primary sources, by far the most detailed and most authoritative is Ilyichev's March 1945 intelligence report, so it will be relied upon heavily here. Details from that report are supported by more general comments from Ilyichev's November 1944 intelligence report and the documents of Schumann, Trinks, Diebner, and Guderley. The most relevant design details from these sources are summarized on p. 4157.

The results of the following analysis are consistent with those of previous analyses [Eilers 2007, 2015; Mineev and Funtikov 2007].

(Can any information on wartime German work be extrapolated from the postwar Soviet program, especially RDS-2/Joe-2 (or later tests)? Soviet rockets were highly derivative of German rockets. The Soviet nuclear program and designs were likely highly derivative of German work as well, although RDS-1/Joe-1 was directly copied from the U.S. Fat Man design.)

Figure D.1037: Scale drawing of Fat Man design according to unclassified sources [https://commons.wikimedia.org/wiki/File:Fat_Man_Internal_Components.png].

Table D.12 compares the Gadget/Fat Man design details from unclassified sources with extrapolated parameters for what the March 1945 Thuringian device design may have been. Each major component will then be discussed briefly.

Component	Gadget/Fat Man	Thuringian Device
Neutron initiator	$\sim$ 7 g beryllium/polonium-210 "urchin" 1.25 cm radius	Deuterium + lithium with high voltage $\sim$ 1.25 cm radius and/or external 6 MeV betatron
Pit	6.2 kg ^{239}Pu 4.6 cm radius	**For test:** <1 kg inner layer of ^{235}U with $\sim$ 5–10 kg natural or low-enriched U outer layer **For deployment:** $\sim$ 5–10 kg ^{235}U $\sim$ 5 cm radius
Tamper/ reflector	108 kg natural U 11.1 cm radius	$\sim$ 100 kg natural U $\sim$ 11 cm radius
Neutron absorber	Boron-10 plastic 3.2 mm thick	$\sim$ 1.3 kg cadmium $\sim$ 1 mm thick
Pusher	130 kg aluminum 23.5 cm radius	$\sim$ 130 kg aluminum $\sim$ 23 cm radius
Explosive	Composition B and baratol 2500 kg, segmented $\sim$ 70 cm radius	TNT, RDX, and liquid oxygen $\sim$ 1400 kg, segmented $\sim$ 63 cm radius
Explosive case	$\sim$ 180 kg aluminum 72.5 cm radius	$\sim$ 140 kg aluminum $\sim$ 64 cm radius
Ballistic case	Steel 4.5 mm thick 75 cm radius	$\sim$ 190 kg steel $\sim$ 4.5 mm thick 65 cm radius
Overall radius	75 cm	$\sim$ 65 cm
Total mass	3000 kg (bomb only) 4670 kg (with shell and fins)	$\sim$ 2000 kg
Delivery system	Boeing B-29 heavy bomber	A-4, A-9, or A-9/A-10 ballistic missile
Explosive yield	20 kilotons	**For test:** < 1 kiloton **For deployment:** $\sim$ 5–100 kilotons

Table D.12: Comparison of the U.S. Gadget/Fat Man implosion design (from unclassified sources) with extrapolated design parameters of the March 1945 Thuringian device.

A. Neutron Initiator

According to the unclassified references, fission bombs are generally equipped with a neutron source or initiator, which provides neutrons to initiate a fission chain reaction just as the fission fuel is being compressed toward its maximum density by implosion with conventional explosives. These references also indicate that the Gadget/Fat Man design used an internal polonium-210/beryllium initiator nicknamed the "urchin" that produced neutrons when crushed at the center of the bomb, and that modern bombs use an external (not inside the imploding part of the bomb) tube filled with deuterium and tritium gas that produces high-energy "fast" fusion neutrons when high voltage (several thousand volts) is applied.

There are at least five possible neutron initiators that could have been used in the Thuringian device, and there is some evidence for each one. Perhaps combinations of these were used to provide redundancy (in case one failed) or to increase the number of initial neutrons, or perhaps they were intended to be used in different versions of the bomb:

1. **Fusion fuel with high voltage at the center of the bomb.** Ilyichev's March 1945 report gave three similar descriptions (p. 4485):

    (a) "1. High-voltage discharge tube, which is charged by special generators."

    (b) "Initiator or bomb fuse: Consists of a special tube, which creates fast neutrons. It is charged by special generators, which create high voltage inside the tube. As a result, fast neutrons attack active material."

    (c) "The bomb ignition is carried out with the help of a high-voltage discharge tube. It forms a flow of neutrons, which attack the active material. When the flow of neutrons impacts upon uranium, element 93 fissions, which speeds up the creation of a chain reaction."

    These three descriptions seem to refer to a high-voltage tube that is filled with fusion fuel (deuterium, tritium, and/or lithium) and produces fast neutrons when a high voltage is applied to the tube. Those neutrons initiate fission reactions in the uranium, releasing more neutrons and starting the fission chain reaction. (The term "Element 93" was widely and scientifically loosely used in the German nuclear program to mean uranium that had absorbed a neutron, sometimes meaning neptunium and sometimes plutonium. Here it simply seems to mean the excited uranium compound nucleus, just after it has absorbed a high-energy fusion neutron and just before it fissions.)

    Ilyichev made it clear that the neutron initiator was at the center of the bomb; he described the core of the bomb as a

    > uranium 235 [...] sphere with an opening into which an initiator is inserted. Once this is done, the opening is sealed by a cork made of uranium 235.

    Due to the constraints of the small volume available at the center of the fission fuel pit, the requirement to avoid including any materials that could hinder the nuclear reactions, and the need for the electrical connections to the central neutron initiator to be functional during the implosion process, the internal high voltage fusion neutron source would need to have a very ingenious design. In fact, after the war Kurt Diebner obtained a patent on just such a high voltage fusion neutron source at the center of an implosion bomb (p. 4261).

2. **External fusion fuel with high voltage.** Since this neutron initiator would be external to the imploding part of the bomb and not be at the center of the bomb, there would be far fewer constraints on its design, which is why the unclassified references report that most modern bombs have used this method. High-voltage tubes that used fusion fuel to produce neutrons were well known and used in the wartime German nuclear program (pp. 3958–3970, 4281–4327).

3. **Internal fusion fuel (without high voltage).** Even without high voltage, fusion fuel placed at the center of the bomb might experience sufficient compression and heating during the implosion process that it would undergo some fusion reactions. While these fusion reactions would not create a measurable amount of released energy (as confirmed by the efforts of Schumann, Trinks, and others to implode pure fusion fuel), they might produce enough neutrons to initiate a fission chain reaction in the surrounding, imploding fission fuel. After the war, Schumann and Trinks and also Diebner published diagrams showing fusion fuel (without high voltage) at the center of an imploding uranium sphere (pp. 4229–4267).

4. **An internal polonium-210/beryllium urchin-like neutron initiator.** Although such an initiator was used in the early U.S. fission bombs, it is not mentioned in existing documents about German bomb designs. However, general use of an alpha emitter (such as radium, polonium, etc.) plus beryllium to produce neutrons was well known and widely practiced in the German nuclear program (see for example pp. 3374 and 4327). Many tons of beryllium were produced (p. 4096). A special installation also produced polonium-210. In fact, on 28 February 1945, just four days before the 4 March test in Thuringia, Kurt Diebner and Walther Gerlach appropriated Germany's entire stock of prepared polonium for a purpose that was too secret to specify (p. 4540).

5. **An external compact betatron directing electrons with energies of at least 6 MeV toward the center.** The >6 MeV electrons would produce <6 MeV gamma-ray photons in the uranium via bremsstrahlung and other absorptive processes, the photons would induce photofission reactions in the uranium, and neutrons would be released. Ilyichev's March 1945 report seems to indicate that the fission bombs tested in Thuringia used this process (p. 4487):

   > Ahead of this, before the explosion, the uranium sphere is irradiated with gamma-rays, the energy of which does not exceed 6 million electron volts [MeV], which many times increases its explosive qualities.

   The more initial neutrons are provided via the betatron or other methods, the larger the resulting fission chain reaction that can occur during the brief time before the bomb core blows apart—thus the betatron-induced radiation "many times increases its explosive qualities" as stated by Ilyichev. The betatron would also need "special generators, which create high voltage," so that part of Ilyichev's description could apply to betatron and/or high-voltage fusion neutron initiators.

   Werner Grothmann also appeared to refer to this type of neutron initiator (p. 5041).

   The basic physics of this process has been described in detail [Wagemans 1991, pp. 103–197]. Remarkably, documentation demonstrates that German scientists were aware of this process mediated by 5–6 MeV gamma rays no later than 1941 (p. 3814). In one of the most detailed yet unclassified modern references on nuclear weapons, Carey Sublette described the use of this process as a neutron initiator for fission bombs [Sublette 2019, Section 4.1.8.2]:

> An additional type of ENI [External Neutron Initiator], not based on fusion reactions, has been successfully tested but apparently never deployed. This is the use of a compact betatron, a type of electron accelerator, to produce energetic photons (several MeV). These photons cause photon induced fission, and photon → neutron reactions directly in the core.

Intriguingly, when Diebner fled Stadtilm ahead of U.S. forces, among the papers he left behind was a whole folder worth of papers on betatrons (p. 3862). A number of betatrons were available for the wartime German nuclear program (Appendix C). In particular, a betatron model produced by Siemens-Reiniger Werke in Erlangen was specifically described as having an energy of 6 MeV (pp. 3088–3089, 3957–3970). That betatron weighed a relatively modest 272 kg, and lighter versions may have been constructed too.

The United States did not begin any serious work on betatrons as neutron initiators until 1946. Could that postwar work have been based on what U.S. investigators learned about the wartime German nuclear program? The *Manhattan District History* reported [Supplement to Manhattan District History Book VIII, Los Alamos Project (Y) Volume 2, Technical, pp. IV-13–IV-14. https://ia803409.us.archive.org/14/items/ManhattanDistrictHistory/]:

> THE BETATRON GROUP [...] 4.55 Experiments were conducted throughout 1946 on photo fission thresholds in normal uranium, U^{235}, U^{238} and plutonium. The most dependable results have come from the use of a shielded paraffin geometry about five feet from the betatron. These findings indicate that all fissionable materials (such as plutonium, normal uranium, and U^{238} have thresholds at about 5.2 Mev. However, this work is not conclusive as it has been observed that the threshold for the production of neutrons from the betatron is also 5.2 Mev. Therefore, there is a doubt as to whether the fission observed is neutron produced fission or gamma fission.

According to further information from Carey Sublette, the United States actually successfully demonstrated a betatron neutron initiator in a fission bomb on 1 June 1952 in the George test of Operation Tumbler-Snapper [https://nuclearweaponarchive.org/Usa/Tests/Tumblers.html]:

> This device (code named XR2) used a Mk 5 bomb assembly. The test was intended to gather additional data on the initiation time vs yield curve. A novel feature of this test was the use of an external initiator—in this case employing a device called a betatron (which is a circular electron accelerator). In this test the high energy electrons were used to generate high energy X-rays that induced photo-fission in the core to initiate the chain reaction. The betatron allowed very accurate control of initiation time. The test device had a diameter of 40 inches and weighed 2700 lb, the predicted yield was 30 kt.

Whatever other neutron initiators may have been present or considered, if Ilyichev's description is correct, at least a small amount of fusion fuel was at the center to serve as a neutron source when triggered with high voltage. If that fusion fuel was deuterium + tritium or deuterium + lithium (but not pure deuterium, which is harder to fuse), it may have produced further high-energy neutrons once the surrounding fission fuel reached high enough temperatures and pressures. If so, those additional fusion neutrons could have significantly increased the number of fission reactions that could occur in the fission fuel before that fuel was scattered by the explosion.

In previous experiments, Schumann and Trinks had tried unsuccessfully to initiate reactions in pure fusion fuel by imploding it with conventional explosives [Irving 1967, pp. 193–197; Karlsch 2005, pp. 144–155; Nagel 2016, pp. 220–242]. If the designers of the Thuringian device did not expect further reactions from the central fusion fuel after the momentary high voltage, yet fusion reactions in the center and fission reactions in the surrounding U-235 mutually aided each other, the yield of the device could have been boosted to be significantly larger than the designers had expected, especially if only a small amount of fission fuel was used. This could explain comments from Wachsmut and Grothmann that the energy yield and casualties were much larger than expected. Potentially this might also explain why there may have been a second and apparently less dramatic test on 12 March 1945 (according to Werner), if the scientists wanted to run the experiment again but without the boosting effect, in order to make sure they fully understood how much difference the boosting effect had made and/or how well their design imploded under more controlled conditions.

On the other hand, perhaps the designers intended for fusion reactions to continue in the center and for fusion neutrons to boost the number of fission reactions in the surrounding fission fuel. In that case, the experiments imploding pure fusion fuel might be viewed merely as preliminary tests before imploding the full fission-fusion design. If one makes some allowances for Ilyichev's specific wording, the center might have been filled with a significant amount of fusion fuel, potentially up to several grams:

- Deuterium-tritium gas would be the most effective [Gsponer and Hurni 2009, p. 10]. Gram quantities of deuterium could easily have been spared from the heavy water production programs. Alfred Klemm mentioned that there was apparently some sort of secret wartime production and use for tritium (p. 4346). Tritium could have been produced by bombarding either deuterium (or heavy water) or lithium with neutrons, in either a fission reactor or a particle accelerator.

- Solid lithium-6 deuteride might also be effective [Gsponer and Hurni 2009, p. 10]. Alfred Klemm produced gram quantities of lithium-6 in his laboratory (pp. 4344–4347), and his process could have been replicated elsewhere. A number of documents show that there was wartime work using lithium and deuterium together as fusion fuel (pp. 4305–4341). Because lithium deuteride is solid and not a gas or cryogenic liquid, it makes a very convenient material for bombs.

- Pure deuterium might conceivably have worked in the high-voltage neutron initiator, but probably would not have been useful for producing further fusion neutrons during the implosion [Gsponer and Hurni 2009, p. 10].

B. Pit

According to the unclassified sources, “pit” is the customary name for the fission fuel in a bomb. Ilyichev’s March 1945 report described the pit of the Thuringian device: “Active bomb material is uranium 235. It represents a sphere with an opening into which an initiator is inserted. Once this is done, the opening is sealed by a cork made of uranium 235. ...A shock from the explosion of the external layer of TNT mixed with liquid oxygen takes place, which is directed toward the center. This allows the uranium to reach a critical mass.”

Although Ilyichev described the fission fuel as uranium-235, uranium-233, neptunium-237, or plutonium-239 might conceivably have been used instead, so we will consider all four possible fission fuels. Table D.13 gives the critical masses for spheres of uranium-233, uranium-235, neptunium-237, or plutonium-239 under various ideal conditions. Critical masses assuming no compression from implosion, no surrounding neutron reflector/tamper, and no fusion neutrons are taken from unclassified information [Bruce Cameron Reed 2015a, 2019; Sanchez et al. 2008]. At most, a single ideal shock wave could compress the fission fuel density by a factor of 4, or reduce the critical mass by a factor of $4^2 = 16$ [Sublette 2019, Section 2.1.4]. Similarly, at most an ideal neutron reflector could reduce the critical mass by a factor of $2^3 = 8$ [Serber 1992, p. 31]. Neutrons from fusion reactions at the center could also significantly reduce the critical mass; the exact factor of improvement depends on a number of details, but some theoretical predictions of the fusion-assisted critical mass are as low as 10 grams [Winterberg 2010, pp. 36, 206–208]. Of course, these are theoretical minimum values for the critical mass under absolutely ideal conditions. Real systems would have various inefficiencies and design tradeoffs and hence larger critical masses. Nonetheless, the critical masses in Table D.13 give some idea of the range of design possibilities that may have been involved in the Thuringian device.

The fission pit in the Thuringian device could have used one of these possible fuels, or it could have combined two or more of the possible fuels. If Germany only possessed a very limited supply of any individual fission fuel, it may have seemed especially attractive to combine them to produce a functional device (or as many functional devices as possible).

Conditions	**Uranium-233**	**Uranium-235**	**Neptunium-237**	**Plutonium-239**
No compression **No reflector** **No fusion**	14.2 kg	45.9 kg	57.0 kg	16.7 kg
Max compression **No reflector** **No fusion**	0.888 kg	2.87 kg	3.56 kg	1.04 kg
Max compression **Max reflector** **No fusion**	0.111 kg	0.359 kg	0.445 kg	0.130 kg
Max compression **Max reflector** **Fusion neutrons**	< 0.111 kg	< 0.359 kg	< 0.445 kg	< 0.130 kg

Table D.13: Critical masses for spheres of uranium-233, uranium-235, neptunium-237, or plutonium-239 under various ideal conditions.

While Table D.13 assumed that the U-235 was 100% enriched, that would not be required. In fact, the Little Boy bomb that the United States dropped on Hiroshima used 64 kg of 80% enriched U-235, which obviously worked. 70% enriched U-235 would also work but would require approximately twice the critical mass of 100% enriched U-235 under the same conditions (compression, reflector, fusion boost, etc.). Similarly, 45% enriched U-235 would require approximately four times the critical mass of 100% enriched U-235 under the same conditions [Sublette 2019]. Bomb performance would become much worse or impossible with enrichment levels significantly lower than those levels.

Grothmann reported that the device was tested with a very small amount of fission fuel but ready to be deployed with a much larger amount. Possible numbers might be < 1 kg for the tested version and ∼5–10 kg for the version to be deployed. Rundnagel specifically mentioned 8 kg for what was apparently the fission pit stored in a safe. Based on information about implosion device designs from the unclassified sources, it seems likely that the pit would have had a deployed mass in the range

$$M_{\mathrm{pit}} \quad \approx \quad 5 - 10 \text{ kg} \tag{D.69}$$

For the implosion of the test version to function as intended in the deployable version, any amount of fission fuel (U-235, or possibly U-233, Np-237, Pu-239, or some combination thereof) that was omitted from the test version would have been replaced with a less precious but similarly dense material for the outer pit, with the remaining true fission fuel at the inner surface of the pit. By far the best and most logical replacement would be low-enriched uranium, which may have been available, or natural uranium, which certainly was available. Considering that the density of uranium is 19.1 g/cm^3 and that of plutonium is 19.8 g/cm^3, other possible replacement materials include gold (19.3 g/cm^3), tungsten (19.3 g/cm^3), and rhenium (21.0 g/cm^3). Any of those materials would have also made a good neutron reflector to keep as many neutrons as possible within the small amount of fission fuel. Natural or low-enriched uranium would have acted as a good neutron reflector and also to some degree as additional fission fuel.[33]

Since U-235 makes up only 0.0072 of natural uranium, 13.9 kg of natural uranium would need to be completely processed to obtain 100 g of pure U-235, or 694–1390 kg of natural uranium would need to be processed to obtain 5–10 kg of pure U-235. (Of course, the U-235 may not have been enriched to 100% purity.) Any strategically useful nuclear weapons program would require multiple bombs and hence at least a few tons of completely processed natural uranium. Exactly how far did uranium enrichment programs progress during the war (p. 5116)?

Alternatively, could enough U-233 fission fuel have been produced from thorium-232, or enough Pu-239 or Np-237 fission fuel have been produced from uranium-238, using an operational fission reactor somewhere and/or particle accelerators (p. 5129)?

---

[33] Large amounts of gold were available in the German-speaking world during the war, as shown by the large stashes of gold that were found at the end of the war.

Large quantities of tungsten were also available, as indicated for example by BIOS 684, *Production of Molybdenum & Tungsten for Radio Valves & Electric Lamps, Metallwerke Plansee, Reutte, Tyrol,* p. 16: “During the war the finished Tungsten production [from this factory] was stated to be 1½ tons per month for which they required 3 tons of Oxide. For carbide manufacture they used about 4 tons per month of metal powder made from oxide.” For another example of tungsten production, see BIOS 1356, *Grinding and Treatment of Minerals.*

Rhenium was available but much more scarce and therefore unlikely to have been used for this purpose [FIAT 697, 750].

C. Reflector/Tamper

According to the unclassified sources, the reflector serves both to reflect neutrons back into the pit and also (if it has much more mass than the pit) as a tamper to slow the explosion of the pit long enough to allow more fission reactions to occur. The most logical reflector/tamper material would be natural or low-enriched uranium. Although Ilyichev's March 1945 report did not specifically mention a reflector or tamper, it may have simply lumped the uranium pit and uranium reflector/tamper together in describing the inner part of the bomb as being "filled with uranium." Intriguingly though, Ilyichev did initially list a "delay mechanism" between the "sphere made of metal uranium 235" and the aluminum "protective casing," then go on to give more detailed descriptions of the uranium-235 and the protective casing but not the delay mechanism between them. Considering the imperfections inherent in translating from specialized scientific language to common language and also from German to Russian in a spy's brief report, "delay mechanism" would actually be a fairly accurate succinct description of the tamper's function.

According to the unclassified sources, the Gadget/Fat Man reflector/tamper was 108 kg of natural uranium. It seems reasonable to assume that the Thuringian device also had a tamper with a mass in the neighborhood of:

$$M_{\text{tamper}} \approx 100\text{ kg} \tag{D.70}$$

If for some reason it was decided not to use uranium for the reflector/tamper, the same alternative materials that might have formed the outer pit for the test version would also make good alternative materials for the reflector/tamper: gold, tungsten, and rhenium. Thorium (11.7 g/cm^3) and lead (11.3 g/cm^3) are lower density but might also be possibilities. Beryllium (1.85 g/cm^3) has a very low density and would not make a good tamper (unless combined with a heavier element), but it is an excellent neutron multiplier/reflector.

All of those candidate tamper materials would have been readily available in sufficient quantities in wartime Germany, with the possible exception of rhenium.

D. Neutron Absorber

According to Ilyichev's March 1945 report: "The uranium sphere is encased in a protective aluminum casing, which is covered by a layer of cadmium. This significantly impedes thermal neutrons emanating from uranium 235, which can cause premature detonation." According to the unclassified sources, in the Gadget/Fat Man design, the inner surface of the aluminum pusher was lined with a 3.2-mm-thick layer of plastic that was rich in boron-10. The boron-10 was intended to absorb any fast neutrons escaping from premature spontaneous individual fission events in the pit, so that they would not enter the hydrogen-rich conventional explosives, slow down to "thermal" speeds that are much more effective at inducing fission reactions, and find their way back into the pit to cause even more premature fission events.

Cadmium is also an excellent neutron absorber and would have served the same purpose in the Thuringian device. It seems likely that it was on the inner surface of the pusher, as the boron-10 was in Gadget/Fat Man, although that is somewhat unclear from Ilyichev's report.

Erich Schumann also mentioned a layer of cadmium in implosion bomb designs (p. 4254). After the war, a "capable young engineer" in Poland told the U.S. embassy there that "one of the best if not the only material for atomic bomb containers is cadmium" (p. 4255), which may have reflected knowledge that he gained from the construction and/or testing of a German fission bomb in Poland.

Cadmium was produced in large quantities in wartime Germany and widely used as a neutron absorber in the German nuclear program (p. 4148). Because cadmium is so dense (8.65 g/cm^3) compared to the density of boron or plastic (< 2 g/cm^3), only a very thin layer of cadmium would have been needed, probably less than 1 mm. German cadmium is known to have been produced in foils of thickness 1 mm or less, which could have been suitable for covering the aluminum pusher. For even better uniformity of coverage, especially to avoid any asymmetries during the implosion process, the cadmium could have been electroplated onto the aluminum. Technologies for electrodepositing cadmium, and electroplating layers onto aluminum, are documented to have existed in wartime Germany (p. 4148).

Assuming that the cadmium layer was on the inner surface of the aluminum pusher and had a radius of 11 cm (comparable to the inner pusher radius in Gadget/Fat Man), thickness of 1 mm, and density of 8.65 g/cm^3, its mass would have been:

$$M_{\text{cadmium}} \approx 4\pi\,(11\text{ cm})^2\,(0.1\text{ cm})\,\frac{8.65\text{ g/cm}^3}{1000\text{ g/kg}} \approx 1.3\text{ kg} \tag{D.71}$$

E. Pusher

Ilyichev's March 1945 report stated: "The uranium sphere is encased in a protective aluminum casing." From the unclassified sources, the Gadget/Fat Man design used a 130 kg aluminum "pusher" between the conventional explosive and the uranium reflector/tamper, so it seems reasonable to assume a comparable mass for the Thuringian device's aluminum pusher:

$$M_{\text{pusher}} \approx 130\text{ kg} \tag{D.72}$$

Because the aluminum pusher's density (2.70 g/cm^3) is higher than that of the explosive (~ 1.6 g/cm^3) but lower than that of the uranium (19.1 g/cm^3), the pusher helps to efficiently transfer the imploding shock wave from the explosive to the uranium.

There is some evidence that the aluminum pusher and aluminum explosive case spherical shells for fission implosion bombs were produced on Usedom peninsula (p. 4270), but if not, suitably sophisticated aluminum production and machining was widespread in wartime Germany (p. 4126).

F. Explosive

Ilyichev's March 1945 report stated: "After the layer of cadmium, it is placed inside explosives that consist of porous TNT saturated with liquid oxygen; TNT is made up of bars of a specially chosen shape. The inner surface of the bars has a spherical curvature, which is the same as that of the external surface of the cadmium layer. Each of the bars is supplied with one detonator or two electrical fuses. ...Liquid oxygen is pumped through the opening inside a protective casing, which covers the TNT. ...The detonating mechanism detonates the explosive matter, after which a shock from the explosion of the external layer of TNT mixed with liquid oxygen takes place, which is directed toward the center."

Most of the interior of the Gadget and Fat Man bombs was filled with TNT-based explosives (composition B and baratol) with shapes and a segmented design intended to optimize the creation of a spherical implosive shock wave. Thus one would expect something very similar in the Thuringian device, especially given the participants' extensive experience designing and testing implosion devices powered by conventional explosives [Irving 1967, pp. 193–197; Karlsch 2005, pp. 144–155; Nagel 2016, pp. 220–242]. Erich Schumann and Walter Trinks demonstrated a sophisticated knowledge of TNT, hexogen/RDX, other explosives, and explosive lenses using combinations of those explosives (pp. 4187–4255). There were also many other experts on implosion techniques, such as Rolf Engel, Rudi Schall, and Hubert Schardin.

Ilyichev said the Thuringian device used TNT, although that might possibly mean any of several TNT-related explosives as in the Gadget/Fat Man design. The average density of solid TNT is 1.654 g/cm^3. If the TNT-based explosive were porous to allow for liquid oxygen penetration, its density would be somewhat lower, say perhaps $\rho \approx 1.4$ g/cm^3.

Assuming that the Thuringian device's explosive layer had an outer radius of approximately $R_o = 63$ cm (slightly less than Ilyichev's stated 65 cm outside radius for the case), an inner radius of approximately $R_i = 23$ cm (if the pusher had an outer radius similar to that in Gadget/Fat Man), and an average density of $\rho = 1.4$ g/cm^3, the explosive layer's mass would be:

$$M_{\text{explosive layer}} \;=\; \frac{4}{3}\pi\left(R_o^3 - R_i^3\right)\rho \;\approx\; 1400\text{ kg} \tag{D.73}$$

TNT molecules ($C_7H_5N_3O_6$) contain relatively few oxygen atoms and normally release their explosive energy by decomposing into a number of smaller oxygen-deficient molecules. Without providing added oxygen, detonation releases 4.184 GJ of energy per ton of TNT.

If enough liquid oxygen were provided, all of those TNT decomposition products could be fully oxidized, and significantly more explosive energy would be released. With complete oxidation, detonation releases 14.5 GJ per ton of TNT, 3.47 times as much energy as without added oxygen.

Thus the provision of liquid oxygen might make the ~1400 kg of explosives in the Thuringian device comparable to up to ~4850 kg of explosives without added oxygen. Depending on the detailed chemical composition of the explosives (the relative amounts of TNT, hexogen, etc.) and the efficiency with which the liquid oxygen was utilized, the ~1400 kg of explosives in the Thuringian device could easily have been quite comparable to or even significantly more powerful than the 2500 kg of explosives in the Gadget/Fat Man design.

G. Explosive Case

According to Ilyichev's March 1945 report: "TNT is covered by a protective layer made of a light aluminum alloy. A blasting mechanism is attached on top of this casing." From the unclassified sources, the Gadget/Fat Man design used a cork-lined aluminum case to enclose the explosives. The aluminum case of the Thuringian device may have been unlined, or the Soviet spy may have simply not known about or considered it worth mentioning the lining. If the aluminum explosive case had an outside radius of $R = 64$ cm (just smaller than Ilyichev's quoted radius for the outer steel case), a thickness of 1 cm, and a density of 2.70 g/cm^3, its mass would have been

$$M_{\text{aluminum case}} \;\approx\; 4\pi\,(63.5\text{ cm})^2\,(1\text{ cm})\,\frac{2.70\text{ g/cm}^3}{1000\text{ g/kg}} \;\approx\; 140\text{ kg} \tag{D.74}$$

As already mentioned, the aluminum pusher and aluminum explosive case spherical shells for fission implosion bombs may have been produced on Usedom peninsula (p. 4270), but in any event, suitable aluminum production and machining was widespread in wartime Germany (p. 4126).

H. Ballistic Case

Ilyichev's March 1945 report stated: "An exterior casing of armored steel is installed above the blasting mechanism." It is not clear if the steel case was actually installed on the Thuringian device as tested, or if it only would have been installed on deployed versions. The tested Gadget bomb did not include a steel case, but the deployed Fat Man bomb had an outer 4.5-mm-thick steel case.

Steel alloys have densities in the range of 7.75–8.05 g/cm^3, so one may use an average density of 7.9 g/cm^3. If the Thuringian device had a steel ballistic case with an outside radius of $R = 65$ cm and the same thickness as Fat Man's case (0.45 cm), the mass of the case would have been:

$$M_{\text{ballistic case}} \approx 4\pi\,(64.8\text{ cm})^2\,(0.45\text{ cm})\,\frac{7.9\text{ g/cm}^3}{1000\text{ g/kg}} \approx 190\text{ kg} \qquad \text{(D.75)}$$

I. Overall Radius

Ilyichev's March 1945 report stated that the bomb diameter was 1.3 m (65 cm radius). On the other hand, his November 1944 report gave the bomb diameter as 1.5 m. That difference in numbers might mean that the Soviet spy's November details were more approximate (consistent with the much shorter and much less detailed November report). Alternatively, it might mean that the Germans had been able to reduce the bomb diameter from 1.5 m to 1.3 meters between November 1944 and March 1945, for example by adding the liquid oxygen to reduce the amount of TNT required.

J. Total Mass

Ilyichev's March 1945 report gave the bomb's weight as "approximately two tons." The weight was not stated more precisely, and it is not entirely clear if the weight given includes the outer steel ballistic case or not.

Adding up all of the extrapolated Thuringian device component masses from Table D.12 (including the ballistic case) yields a total mass of:

$$M_{\text{total}} \approx 2000\text{ kg} \qquad \text{(D.76)}$$

Thus the total mass is in excellent agreement with Ilyichev's reported estimate.

K. Delivery System

According to Ilyichev's March 1945 report: "A fairing made of a light alloy can be installed on top of the armored casing for future installation on a rocket of the V-type." This fits very well with all known data. V-2/A-4 rockets had become fairly reliable methods of delivering a payload to a target up to several hundred km away and could not be shot down by air defenses (unlike bomber aircraft or V-1 cruise missiles). Rockets with much longer ranges (A-4b, A-9, A-9/A-10) were apparently under development. The maximum payload fairing diameter for all of these rockets was approximately 1.37 meters, so a bomb with a diameter of 1.3 m would have been the largest implosion device that could fit within that space. (Alternatively, the bomb might have been placed in the middle of the rocket at the center of gravity, but space between the propellant tanks there would also be quite constrained.) These rockets used liquid oxygen as oxidizer for propulsion, and hence liquid oxygen would have been readily available to supplement the TNT in the bomb. The standard payload for the V-2/A-4 was one ton. If the Thuringian device was two tons, that would explain why it was never deployed militarily in the well tested standard V-2/A-4 rocket. It would have required either a modified V-2/A-4 with a larger payload capacity or one of the more advanced rocket designs, and such improved rockets were apparently still in the experimental phase (see Appendix E).

L. Explosive Yield

As discussed in Section D.15.4, the blast radius of 500–600 m stated in Ilyichev's March 1945 report suggests that the explosive yield of the Thuringian device as tested was around 200–350 tons. However, the device diameter, mass, and design details given by Ilyichev seem like those of a full-fledged fission bomb comparable to the 20-kiloton Gadget/Fat Man design, as shown in Table D.12. If the Thuringian device had been furnished with a full-sized ($\sim$ 5–10 kg) pit of high-quality fission fuel (U-235, U-233, or Pu-239) comparable to that in Gadget/Fat Man, it seems likely that it would have had a comparable explosive yield in the $\sim$ 20-kiloton range. If the pit was smaller and/or the fission efficiency was lower than in the U.S. design, the explosive yield may have been only a few kilotons. If the pit was $\sim$ 5–10 kg of high-quality fission fuel and significant fusion neutron boosting occurred from the deuterium-tritium (or deuterium-lithium) neutron initiator at the center, or if the center was deliberately filled with deuterium-tritium (or deuterium-lithium) fusion fuel, the device could have fissioned far more of its fission fuel and hence achieved far larger yields—potentially $\sim$ 100 kilotons or more for a $\sim$ 10 kg pit with $>$ 50% efficiency.

These estimates from physical considerations are supported by a number of historical sources that stated the expected blast radius of the deployed fission bomb. The estimates from these sources were in the range of 1–4 km, depending on how much fission and fusion fuel were used and what the fission efficiency was. Using Eq. (D.49), those blast ranges correspond to an expected explosive yield of ~1.6–100 kilotons, as summarized in Table D.14.

Note that these estimates are for the ~1.3-meter-diameter spherical implosion bomb that was described by many sources and analyzed in this section. Other sources mentioned a nonspherical fission bomb that was much smaller and had a yield of less than 1 kiloton (p. 5170). There were also many sources that mentioned an H-bomb weighing 6 tons that would have been far more powerful, with a 10-kilometer blast radius and ~1.6 megaton explosive yield (p. 5171–5172).

Historical sources	Expected blast radius	Corresponding yield
pp. 4590, 4600, 4602, 4605, 4894	~1 km	~1.6 kiloton
pp. 4600, 4703	~1.5 km	~5 kilotons
pp. 4605, 4674	~2 km	~13 kilotons
pp. 4400, 4595, 4674, 5011, 5012	~3 km	~40 kilotons
pp. 4176, 4595, 5011	~4 km	~100 kilotons

Table D.14: Expected blast radii and corresponding explosive yields for the German fission bomb as stated by various historical sources. The different expected blast radii originated from different assumptions about the amount of fission and fusion fuel used in the bomb and the expected efficiency of fission fuel consumption during the explosion.

D.15.6 Possible Evidence for Other Device Designs

The wartime German rocket program developed and demonstrated dozens of different types of missiles with a wide variety of designs, sizes, and applications. The German jet program produced designs, prototypes, and in some cases production-line models for jet aircraft with a similarly wide range of designs, sizes, and applications. Likewise, wartime German programs on submarines, electronics, chemical warfare, biological warfare, directed energy technologies, and other areas all pursued a wide variety of developments in each of those areas. If a wartime German nuclear program had been run with determination and methods at least comparable to all of those other wartime scientific programs, one would expect it to have developed or at least investigated a whole range of designs, sizes, and applications for nuclear weapons. Indeed, Werner Grothmann stated that there were at least five different nuclear weapon types under development (pp. 4271–4273).

While Ilyichev reported that a 1.3-meter-diameter spherical implosion bomb was tested at Thuringia (p. 4485), and that report seems plausible from the preceding physics analysis, there is considerable evidence to support Grothmann's assertion that the German nuclear program was also working on other nuclear weapons designs.

A. Larger Spherical Implosion Bombs

A spherical implosion bomb is mostly filled with TNT-based explosives, which have an average density of approximately 1.654 g/cm^3. The average density due to the smaller amount of other materials in the bomb does not deviate much from that density; for example uranium tends to be present in much smaller amounts, and its higher density is typically offset by hollow spaces. Thus one may take 1.654 g/cm^3 as an approximate average density for a spherical implosion bomb. For the 65-cm radius of the Thuringian device, that density predicts a total bomb mass of 1900 kg, very close to the 2000 kg estimate reported by Ilyichev in March 1945.

Larger implosion bombs could compress the fission pit to a higher degree, decreasing the probability of failure and increasing the fission efficiency and explosive yield. Larger bombs could also use more fission fuel for a larger explosive yield. The Thuringian device appears to have been limited to a 1.3-meter diameter simply to allow an A-4 or similar rocket to accommodate its size and mass.

1.5-meter-diameter bomb. Ilyichev's November 1944 report gave a bomb diameter of 1.5 meters, or a radius of 75 cm (p. 4481). That may have just been a less accurately reported estimate of the actual 1.3 meter bomb diameter. However, it seems at least as likely that the 1.5 meter value was indeed the correct diameter of the German implosion design as it existed in November 1944, prior to the final push to reduce its size by supplementing the TNT with liquid oxygen. The U.S. Gadget/Fat Man implosion bomb design had a radius of 75 cm (not counting the bomb shell and fins), so the number reported by Ilyichev in November 1944 seems extremely reasonable. At an average density of 1.654 g/cm^3, a 75-cm-radius implosion bomb would have a total mass of 2900 kg, very close to the 3000 kg approximate mass of the U.S. Gadget. Thus one version of the German implosion bomb may have had a diameter of 1.5 meters and a mass of approximately 3000 kg. That would make it more challenging to deliver via rocket, but still quite reasonable for an air-dropped weapon to be delivered by aircraft. Any nuclear weapons design program would have begun earlier in the war, when rockets were still an unproven technology and Luftwaffe aircraft were making routine bombing runs over Allied territory, and would probably have expected the first nuclear weapons to be delivered by aircraft.

1.8-meter-diameter bomb. Reports of earlier German programs producing and testing spherical aluminum shells for secret purposes indicated a diameter of approximately 1.8 meters (p. 4270). If those reports are accurate (and not a misremembering of 1.3-meter- or 1.5-meter-diameter spheres), they would suggest a spherical implosion bomb design with even more conventional explosives, a larger fission pit, and/or a larger hollow space in the center of the pit. At an average density of 1.654 g/cm^3, a 90-cm-radius implosion bomb would have a total mass of approximately 5 tons. If the radius were slightly larger or if the average density (due to larger amounts of uranium and other dense materials) were slightly higher, the bomb mass could be closer to 6 tons. Intriguingly, there were multiple reports of a new type of German bomb that weighed 6 tons, was radioactive, and would be delivered to the United States by a giant rocket (see pp. 4338, 4350–4363, and 5343). The 1.8-meter-diameter spherical aluminum shells were reportedly being produced and tested in Anklam and Friedland, not far from Peenemünde. As already covered, a spherical implosion bomb design could be used with U-235, U-233, or Pu-239 fission fuel, and with or without a small amount of fusion fuel at the center to add neutrons and boost the overall efficiency of the fission explosion. Therefore, even for spherical implosion bombs, there could be a number of variations with different sizes, fuels, and explosive yields.

B. Nonspherical Implosion Bombs

Spherical implosion gives the greatest efficiency and highest explosive yield for a given amount of conventional explosives and fission fuel, since the fission fuel is uniformly compressed from all sides. Likewise the larger an implosion bomb is, the more efficient it tends to be, as discussed above. However, very large spherical shapes are not particularly well suited for air-dropped bombs or for ballistic projectiles. Thus there would be a strong motivation to consider smaller and/or non-spherical implosion bombs, even if their explosive yield would be considerably less than that of a large spherical implosion bomb. Whereas a large fission implosion bomb can have an explosive yield of tens of kilotons and destroy an entire city (like Nagasaki), a smaller non-spherical fission implosion bomb might have a yield on the order of one kiloton or less, but that could still make it useful for destroying certain tactical military targets, especially considering the radioactive as well as the blast effects. As a further motivation, smaller bombs would require less fission fuel than larger bombs; fission fuel would be in short supply in the early phases of any nuclear weapons program, as Werner Grothmann specifically stated that it was for the German program.

In fact, several sources discussed the wartime development of a smaller fission bomb. It was described as a tactical, nonspherical, two-point-ignition, fission implosion bomb that was externally similar to a standard German 250 kg bomb, had a full yield likely less than one kiloton, and was potentially ready for deployment before the end of the war (pp. 4246–4248, 4271–4277, 5030).

C. Gun-Type Fission Bomb

German scientists also appear to have been aware of the gun-type fission bomb design [Karlsch and Walker 2005; Thirring 1946]. However, any development seems to have been focused on the implosion design, since it requires much less fission fuel and has a much higher efficiency than the gun design. The U.S. gun-type fission bomb, Little Boy, had a mass of 4400 kg, diameter of 71 cm, and length of 300 cm. That is far larger than the SC-250-like bomb described by Grothmann, and descriptions of other bombs alleged by Grothmann, Ilyichev, and other sources to have been constructed have geometries very different than Little Boy. Thus from the available evidence, the gun design appears to have been understood but not developed, probably due to its inherent disadvantages relative to implosion designs.

D. Radiological Dirty Bombs

As discussed in Section D.5, several sources stated that Germany possessed one or more operational fission reactors before the end of the war. If that were true, it would have been technologically very straightforward to remove highly radioactive spent fission fuel from a reactor, pack it around a modest amount of conventional explosives in a bomb, and detonate such a device over a target to scatter highly radioactive isotopes over the target area. Such a bomb would have no required critical mass and could be made as large or small as desired, so it could easily be carried by an A-4 or other rocket, missile, or aircraft. Because that approach would be so straightforward once a reactor was operational, and because there was such strong political and military pressure for Germany to develop powerful new weapons, it seems highly likely that this approach would have been pursued. During the war, high-level officials in the United States and United Kingdom wrote classified memos about the possibility of the Germans using such a radiological dirty bomb, although it is not clear if that was purely speculation or based on actual intelligence from Germany [TNA AB 1/608].

E. Layer Cake H Bomb

As summarized in Sections 8.8.9 and D.9 (see especially p. 4280), a large number of declassified and publicly available sources appear to describe a six-ton H-bomb with a planned yield around 1.6 megatons that used a fission implosion device to initiate fusion reactions in lithium deuteride fuel and was expected to be tested in 1945 or 1946 if the war had continued.

Many documents show that there was prewar and wartime work using lithium and deuterium together as fusion fuel (pp. 4281–4349). Because lithium deuteride is solid and not a gas or cryogenic liquid, it makes an ideal fuel for hydrogen (H) bombs. There were multiple reports that the Germans were developing a weapon with a 6-mile blast radius (pp. 4365–4367). From Eq. (D.49), a 6-mile or 10-km blast radius corresponds to an explosive energy of at least $(10,000/85.5)^3 \approx$ 1,600,000 tons of TNT equivalent, or at least 1.6 megatons. This is well beyond the kiloton ranges of fission bombs, as the German scientists knew from basic calculations of fission energies, and suggests that they were developing much more powerful H bombs. Knowledgeable German sources expected to complete a deliverable version of such a weapon later in 1945 or in 1946 (pp. 3401, 4272, 4367, 4334, 4359). If true, that was a feat that the United States and Soviet Union did not actually accomplish until 1953–1955 (Soviet Joe-4/RDS-6s, U.S. Castle Bravo, and Soviet RDS-37).

According to unclassified references, there are two major types of functional H-bomb designs [Goncharov 1996a, 1996b; Chuck Hansen 1988, 2007; Rhodes 1995; Sublette 2019; Wellerstein and Geist 2017]. The simpler one to build is what the Soviets later called a “layer cake” (*sloika*), a spherical implosion bomb with layers of fusion fuel interspersed with layers of fission fuel. The fusion reactions contribute only a modest amount of energy, but a huge number of neutrons that enable the consumption of far more fission fuel than would otherwise be possible.

Since the German program was producing fusion fuel such as deuterium and lithium, building spherical bombs with a diameter of at least 1.8 meters (significantly larger than even the U.S. Gadget/Fat Man fission implosion bomb), and expecting a blast radius corresponding to a megaton-level explosive yield, it is possible that a layer cake H bomb design was under development. (See also p. 4372.) This view might also be supported by the multiple reports of a new type of German bomb that weighed 6 tons, was radioactive, and would be delivered to the United States by a giant rocket (see pp. 4338, 4350–4363, and 5343). Furthermore, the postwar Soviet nuclear program was heavily dependent upon German scientists, materials, and ideas, and the first Soviet H bomb (Joe-4 or RDS-6, tested on 12 August 1953; see p. 1638) employed the layer cake design.

Joe-4 is reported to have weighed 4.5 tons, had a diameter of 1.5 meters, and produced an explosive yield of 400 kilotons; it is also reported that the bomb's yield could have been higher if its surrounding layer of conventional explosives had been better able to compress the layers of fission and fusion fuel [Wellerstein and Geist 2017]. (Joe-4's size was apparently constrained by the Soviet desire to make it no larger than the Joe-1 fission bomb, in order to facilitate delivery by aircraft). If there was a wartime German design that was very similar but had 1.5 tons more of surrounding conventional explosives (total weight of 6 tons), its diameter would have been around 1.8 meters, and its explosive yield could easily have been in the 1.5-megaton range.

F. Two-Stage H Bomb

According to unclassified references [Goncharov 1996a, 1996b; Chuck Hansen 1988, 2007; Rhodes 1995; Sublette 2019; Wellerstein and Geist 2017], the second major type of H bomb is a "two-stage" design, in which the dense outer bomb casing surrounds both a fission implosion bomb (the first stage) and a neighboring mass of fusion fuel (the second stage). When the fission bomb detonates, its heat and pressure ignite fusion reactions in the adjacent fusion fuel. If the outer bomb casing is made of fission fuel (even natural uranium), high-energy neutrons from the fusion reactions can trigger extensive fission reactions in the outer bomb casing, making it effectively a third stage of the explosion.

Friedwardt Winterberg, who worked very closely with Kurt Diebner after the war and never worked in the U.S. nuclear program, produced a book of designs for two- or three-stage fusion explosive devices that look rather different than publicly available U.S. H bomb designs but that are deeply steeped in earlier German hydrodynamics and physics research [Winterberg 1981]; see p. 4373. Whereas the outer casing of a U.S. H bomb design is generally depicted as cylindrical in the unclassified references, the outer casing of the Winterberg or Diebner H bomb design has a pronounced Prandtl-Meyer ellipsoidal shape. A surviving 1944 sketch from Walther Gerlach shows an ellipsoid in conjunction with nuclear reactions involving deuterium, which seems to support the wartime origin of Winterberg's ellipsoidal H bomb design (p. 4377). In addition to the more straightforward fission bomb designs, Werner Grothmann mentioned that an H bomb was being developed during the war, and that it was of an entirely different design that "looked like a swollen bomb" (p. 4272). The ellipsoidal H bomb design would seem to fit Grothmann's description perfectly. The multiple reports of a 6-ton bomb (pp. 4338, 4350–4363, and 5343) and a bomb with a 6-mile blast radius (pp. 4365–4367) could also describe this type of bomb.

In 1947, when Edward Teller was trying unsuccessfully to invent a workable design for the U.S. hydrogen bomb, he sent a highly unusual, specific, and urgent request for Siegfried Flügge to help him with a "physics... program... of interest and importance to the national security," stating that Flügge would "be of marked assistance in carrying out the aforementioned program" (p. 4996). Flügge was indeed brought to the United States, and it has never been publicly revealed what he worked on. In fact, late in the war and after the war, there was a large influx of scientists and engineers who came to the United States and/or United Kingdom and who were from or had knowledge of the German nuclear program (p. 1608). Many of those scientists appear to have been closely tied to the wartime German work on H-bombs, and may have especially aided the U.S. H-bomb development program between 1945 and 1954.

If enough archival material can be found, declassified, and released, it would be extremely interesting to find out how far German work on H-bombs may have progressed during the war, and how much that work (and the associated scientists, materials, and plans) influenced postwar work on H bombs in the United States, Soviet Union, or other countries.

D.15.7 Conclusions and Recommended Further Research

This appendix concludes by considering the plausibility of the primary source evidence, nuclear vs. non-nuclear explanations of that evidence, different possible nuclear devices, the reasons for not using any nuclear weapons in the war, the technological state of the German nuclear program relative to that of the United States, and recommendations for further research.

A. Plausibility of the Primary Source Evidence

The fundamental question underlying this appendix is the accuracy of the conventional historical view that Germany made little progress toward nuclear reactors and weapons during the war. While there are many types of potential documentation that Germany may have made significantly more progress than has been commonly acknowledged, the most dramatic proof would be the successful test explosion of a nuclear device. There is at least some evidence of several test explosions: one on or near the Baltic coast in October 1944, one in Poland during or around November 1944, and one or two in Thuringia in March 1945. Of those possible tests, currently there is the greatest amount of evidence for the early-March 1945 Thuringian test.

Wartime and postwar documents show that within the top echelons of the SS, there was a prolonged and intense interest in developing a nuclear weapon, and an expectation around March 1945 that battlefield use of such a weapon was imminent. Likewise, wartime and postwar documents from Diebner, Schumann, Trinks, Guderley, Harteck, Stetter, and others confirm that there were very active research programs on spherical implosion bomb designs, fission reactions, fission fuel production, fusion reactions, and fusion fuel production. The surviving documents do not indicate whether or how those research programs were combined or ultimately tested.

At least ten primary sources specifically address the March 1945 Thuringia test:

1. Ivan Ilyichev's November 1944 intelligence report to Stalin.
2. Ilyichev's 23 March 1945 report to Stalin.
3. Igor Kurchatov's 30 March 1945 response to Ilyichev.
4. Georgy Flerov's two brief May 1945 reports to Kurchatov and 1983 interview.
5. Robert Döpel's 1946 interrogation by the Russians.
6. Cläre Werner's testimony in 1962 and later in life.
7. Heinz Wachsmut's testimony in 1962 and later in life.
8. Erich Rundnagel's 1966 testimony.
9. Oscar Koch's 1960s testimony about a 1945 U.S. intelligence report.
10. Werner Grothmann's 2000–2002 testimony.

The details described in these ten primary sources are remarkably consistent with each other, as shown on p. 4480. The details are also consistent with other wartime and postwar primary sources that reported German work on a fission implosion bomb (see for example p. 4157). As shown in Section D.15.4 above, the details from all of these primary sources agree to a striking degree with the now well-established physics of nuclear weapons.

This may seem like an unacceptably small amount of evidence for such a dramatic historical claim as a German nuclear weapons test. However, even if the claim is true, it is not surprising that there is not more evidence. It is well known that Germans destroyed or buried documentation of military technologies at the end of the war.[34] Motivations for those actions included denying that technology to Allied nations, using that information as a bargaining chip, and/or avoiding imprisonment or execution for war crimes associated with the development, testing, use, or intended use of that technology. It is also well known that Allied nations vacuumed up as much documentation as they could find, and then kept it secret from the other Allies, or claimed it as their own technology, or simply lost the information within their large bureaucracies and the vast amount of material removed from Germany.[35]

Likewise it is not surprising that there is not more witness testimony. According to the ten primary sources, the test occurred in a sparsely populated area, most of the residents who did live there were evacuated ahead of time, and most of the residents who remained were sent to air raid shelters by warnings shortly before the test. Virtually all of the prisoners involved in the test or the preparations were worked to death, died in the test, or were killed afterward by the SS. Anyone else who spent much time at the test site in the hours immediately after the explosion would likely have received enough exposure to die of radiation sickness that would have been unrecognized in the chaos and hardship shortly before and after the end of the war. Scientists and military personnel who were involved would be strongly motivated to permanently conceal the test for fear of being executed for war crimes. Any others involved were threatened by the SS and sworn to secrecy or killed, and would have remained fearful of reprisals from former SS members for the rest of their lives if they revealed what they knew.

The Soviet intelligence reports from Ilyichev, Kurchatov, Flerov, Zhukov, and Döpel seem to prove that there was definitely some sort of test event, even if one might argue about the details of that event. The intelligence reports began at least as early as 15 November 1944, continued into 1946, went all the way to Stalin, and led to the commitment of major Soviet scientists, forces, and resources to investigate. These are certainly not forgeries, and it does not seem plausible that they are merely faulty intelligence about a completely nonexistent event.

[35] See for example Albrecht et al. 1992; Bar-Zohar 1967; Bower 1987; Buyer and Jensen 1948; Byrd 1948; Crim 2018; DOW 1945b, 1946; Gimbel 1986, 1990a, 1990b, 1990c; Goudsmit 1947; Glatt 1994; Hall 2019a; Linda Hunt 1985; Morton Hunt 1949; Jacobsen 2014; Jensen 1948; Jösten 1947; Matthias Judt and Ciesla 1996; Kurowski 1982; Lasby 1971; Mick 2000; Nagan 1947; Nagel 2016; O'Reagan 2014, 2019; Simpson 1988.

B. Nuclear vs. Non-nuclear Explanations of the Primary Source Evidence

All possibilities for what that test event might have been can be considered. Most of those possibilities can be rejected unless the primary sources are greatly in error:

- A conventional bomb would not have the blast radius reported by Ilyichev and Koch, the radioactive effects reported by Ilyichev, Werner, Wachsmut, and Grothmann, the design reported by Ilyichev, Döpel, and Grothmann, or the intense security reported by Ilyichev, Rundnagel, Grothmann, Werner, and Wachsmut.

- A fuel-air explosive device might have caused blast damage to an area as large as reported, but it would not have had the radioactive effects reported by Ilyichev, Grothmann, Werner, and Wachsmut, or the design reported by Ilyichev, Döpel, and Grothmann.

- A chemical agent test might have killed, burned, or sickened as many people as reported, but it would not have the blast radius reported by Ilyichev and Koch, or the design reported by Ilyichev, Döpel, and Grothmann.

- A fuel-air explosive device that dispersed a chemical agent might theoretically account for both the blast damage and the symptoms of the casualties, but would not be consistent with the design reported by Ilyichev, Döpel, and Grothmann, and a fuel-air explosion would be far more likely to incinerate a chemical agent than to efficiently disperse it.

- A radiological "dirty bomb," with radioactive elements packed around and dispersed by a conventional explosive, might explain the radioactive effects, but would not have the blast radius reported by Ilyichev and Koch, or the design reported by Ilyichev, Döpel, and Grothmann.

- A "hydrodynamic" test of a nuclear bomb without any of its nuclear fuel, purely to scientifically validate the design details, would have the outward appearance of a conventional bomb explosion; it would not have the blast radius reported by Ilyichev and Koch, or the radioactive effects reported by Ilyichev, Grothmann, Werner, and Wachsmut.

- A pure fusion device, with fusion fuel at the center of an implosion design powered by conventional explosives, would not produce a significant amount of nuclear reactions, radiation, or energy. Even with over 70 years of effort and steadily improving technology, scientists have not been able to trigger significant fusion reactions with conventional explosives [Gsponer and Hurni 2009, pp. 139–141; Winterberg 2010, pp. 297–298, 302]. Thus such a device would not have the blast radius reported by Ilyichev and Koch, or the radioactive effects reported by Ilyichev, Grothmann, Werner, and Wachsmut. It would also not contain uranium as reported by Ilyichev, Döpel, and Grothmann.

- A pure fission device would be highly consistent with the blast radius reported by Ilyichev and Koch, the radioactive effects reported by Ilyichev, Grothmann, Werner, and Wachsmut, and the design reported by Ilyichev, Döpel, and Grothmann.

- A hybrid fission-fusion device could also be highly consistent with the blast radius reported by Ilyichev and Koch, the radioactive effects reported by Ilyichev, Grothmann, Werner, and Wachsmut, and the design reported by Ilyichev, Döpel, and Grothmann.

C. Type of Nuclear Device

Therefore the only possibilities that seem consistent with the evidence from the primary sources appear to be either a pure fission device or a hybrid fission-fusion device. If it was a fission-fusion device, the fusion reactions would not have made a significant direct contribution to the energy output, but their neutrons could have greatly reduced the critical mass of fission fuel required.

If the device tested had an explosive energy yield of a few hundred tons or so (as found in Section D.15.4), that would make its energy ~ 100 times larger than that of a conventional bomb of the same size, yet ~ 100 times smaller than that of well-known fission bombs such as the Gadget and Fat Man bombs that the United States detonated in July and August 1945. Even in March 1945, Igor Kurchatov was puzzled by the reported energy yield (p. 4496). If the explosive energy of the test was indeed in the few-hundred-ton range, there are three possible explanations:

- The most likely explanation is that the device was a full-sized bomb capable of an energy yield in the range of tens of kilotons if used with a pit containing several kilograms of U-235, but was tested with a pit containing very little U-235, perhaps as little as ~ 100 grams. Any U-235 that Germany had produced would be a highly precious commodity that would be saved for battlefield deployment of such devices, not used up in a test. The Germans would also be reluctant to create a very large blast and very large amount of radioactivity deep in the heart of Germany, especially just for a test. (For the same reasons, several of India's 1998 Shakti nuclear detonations tested devices that produced explosions of less than 1 kiloton each yet successfully demonstrated their designs would have much higher yields if deployed.) This explanation fits well with Grothmann's statements that the test deliberately used only a very small amount of fuel. It is also very consistent with all of the other primary sources.

- A less likely but still possible explanation is that the device was a full-sized bomb, tested with the full amount of U-235, but misfired (for example if the neutron initiator failed or if the implosion was not spherically symmetric), causing the energy yield to be much smaller than expected. Evidence against this explanation includes the statements of Grothmann and Wachsmut that the energy yield was actually larger than expected, the comments of Grothmann that only a small amount of fuel was used, and the military undesirability of using up too much scarce U-235 or making too large of a mess purely for a test.

- Another unlikely but possible explanation is that the device was a small-sized "mini nuke" design, never intended to have a large yield even if deployed on the battlefield. Evidence against this explanation includes the large bomb diameters given in both of Ilyichev's reports, the large bomb mass given in Ilyichev's second report, the statement of Rundnagel that the bomb was designed to use at least 8 kg of fuel, the statements by Grothmann that these late-war efforts were focused on developing a large strategic nuclear weapon that could be delivered by rocket, and the military futility of testing or deploying a low-yield tactical weapon at that late stage of the war.

D. Reasons for Not Using a Nuclear Weapon in the War

One might try to argue that if Germany had really developed a nuclear bomb, it would have immediately used it during the war, so the fact that such a weapon was never used proves that it never existed. However, there are several reasons why Germany may not have used a nuclear weapon even if it had one in its possession. Conceivably any or all of these reasons might be true:

- The weapon may have been developed too late to be deployed. This seems quite plausible if the weapon was still being tested in March 1945 and the area was overrun by Allied forces on 4 April.

- A suitable delivery system for the weapon may have been developed too late or not at all. This also seems quite plausible if—as described by Ilyichev, Schumann, Grothmann, and others—the weapon was intended for delivery by rocket but weighed two tons. Existing A-4 or V-2 rockets were designed to carry a one-ton payload, and any rocket with a larger payload capacity would have still been in the experimental stage.

- There may have been only enough fission fuel for one or a very small number of weapons, and German leaders may have realized that even if those were used, they could not halt the advance of Allied forces into Germany from all sides. This seems very plausible, especially in light of Grothmann's comments about the uncertain political effect of any battlefield use of the weapon, and Grothmann's and Rundnagel's comments about the small amount of fuel.

- German leaders probably realized that if they used a nuclear weapon, Allied forces would respond by killing tens of millions of German civilians with crude but effective WWI-style chemical weapons (mustard agent and phosgene) or other means (pp. 2632–2651). This explanation is highly plausible, since that same reasoning seems to have prevented German leaders from employing the large amounts of advanced nerve gas that the country had in its arsenal (pp. 2632–2651).

- To extend the previous two points, German strategic plans may never have involved the use of just one or two nuclear weapons:

  - In the final years of the war, Allied forces were approaching Germany from all sides; it would have been obvious throughout those final years that destroying one or two Allied cities with nuclear bombs would never halt all of those Allied forces, let alone an Allied counterattack dropping mustard agent, firebombs, etc. on millions of German civilians.

  - Accordingly, the strategic thinking behind the German nuclear program may have been to mass-produce and stockpile nuclear weapons and the means to deliver them. Those weapons would have only been used once their numbers surpassed a capability threshold that would have enabled many simultaneous nuclear attacks [quite possibly in parallel with simultaneous attacks using German nerve agents and other chemical weapons (p. 2651), biological weapons, and/or fuel-air explosives] on Allied targets and the credible threat of further attacks if the Allies launched any counterattacks or if German demands were not met.

  - That approach appears to be supported by Grothmann and other sources that described mass-production or attempts at mass-production for nuclear weapons as well as their delivery methods.
  - Indeed, German officials spoke of plans to end the war within a matter of hours by such an overwhelming attack with their stockpiled weapons of mass destruction. Moreover, after studying German technologies after the war, Allied officials described exactly the same scenario of a massive German nuclear attack. See for example pp. 4549–4550, 4587, 4621, 4627–4665, 4679–4681, 4766, 5038, 5218, 5380, 5454–5466, 5658–5659.
  - If that was indeed the German strategy in the final years of the war, it suggests that the scale and level of advancement of the nuclear weapons/delivery programs may have been quite extraordinary, and that the world may have narrowly escaped a level of devastation that was unthinkable, at least until much later in the Cold War.

- Individual political or military leaders in charge of the deployment of a nuclear weapon may have realized that Germany would lose the war very soon regardless, and feared that they would be executed as war criminals if they actually used the weapon. That same reasoning may have prevented them from employing their nerve gas. For example, according to a 1 April 1945 Allied intelligence document, Luftwaffe General Albert Kesselring mentioned deliberations among Hitler's top staff about whether to use a final secret weapon, referred to as the "desperation weapon," that would cause a "terrible blood bath"; "Kesselring said if Fuehrer gave him order to use weapon he would surrender his command" (p. 4670). Grothmann confirmed this line of reasoning in the high command.

- Individual political or military leaders in charge of the deployment of a nuclear weapon may have realized that Germany would lose the war very soon, and come to individual decisions that they had more to gain personally by secretly offering the nuclear weapons technology and other advanced technologies to Allied countries than by employing the weapon against Allied forces. This is quite plausible since SS General Hans Kammler seems to have been directly in command of all advanced weapons (including any nuclear weapons) in the final stages of the war, and he secretly disappeared to America after faking his death—see pp. 4931–4959 [Agoston 1985; Döbert 2015; Döbert and Karlsch 2019; Karlsch 2014; Michalski et al. 2019; Reuter et al. 2019; Sulzer and Brauburger 2014, 2019a].

E. Technological State of the German Nuclear Program vs. the U.S. Program

Much more work is needed to gather and analyze relevant data from primary sources and physical evidence in order to verify that the Germans indeed tested a nuclear device, and to work out the design details of that device. With that large caveat, the extrapolated design details above and further details in the works of Schumann, Trinks, Diebner, Guderley, and others suggest that the wartime German nuclear program was actually ahead of the wartime and postwar U.S. nuclear programs:

- The implosion design reported by Ilyichev seems very detailed, physically feasible, and deeply grounded in experimental and engineering details. While similar to the U.S. Gadget design, it does not appear to be a carbon copy of that design, suggesting that it was arrived at independently and not by any German espionage of the U.S. program. It seems to be much more than an abstract concept never reduced to practice, or a hasty idea thrown together at the end of the war. It appears to be the end product of a well-funded, long-running, highly scientifically skilled nuclear weapons development program.

- As stated by Werner Grothmann (pp. 4271–4273) and supported by other evidence as discussed in Section D.15.6, the German program appears to have developed not just one nuclear weapon design, but rather a whole range of specialized designs for a variety of strategic and tactical applications. The United States did not have comparable diversity in its own nuclear arsenal until many years after World War II.

- German nuclear scientists appear to have been aware of the gun design, but seem to have focused their work on the implosion design from early on, since that would use much less fission fuel and offer much higher efficiency, which is why the implosion principle is still used in modern bomb designs. In contrast, the U.S. Manhattan Project spent most of its time and resources developing the gun-type design (called Thin Man in the early versions and Little Boy in the final version), and only began a serious program to develop an implosion design (Gadget/Fat Man) in July 1944.

- Germany appears to have conducted a test explosion of a nuclear device on 4 March 1945, four and a half months before the first U.S. test, and the German test appears to have been of a device that, if deployed, would have had a yield comparable to or even greater than the first U.S. fission bombs. If the reported October 1944 Baltic test explosion was real and was a successful nuclear test, that would have been over 9 months before the first U.S. test.

- The United States had produced no functioning nuclear weapons whatsoever by V-E Day, and only three by V-J Day (those detonated at Trinity, Hiroshima, and Nagasaki). In contrast, there is evidence that before V-E Day, Germany may have produced at least three nuclear weapons that were used in successful tests (Sections D.10, D.11, and D.12), and apparently several more that were held in a stockpile for possible military use (e.g., pp. 4182, 4436, 4667, and 4670). If that information is correct, then by the end of the war, Germany held an enormous lead over the United States in the world's first nuclear arms race.

- If allegations are true that the United States removed nuclear weapons technologies from Germany, used enriched uranium and bomb detonators obtained from the German submarine U-234, and relied at least in part upon those captured nuclear weapons technologies, captured enriched uranium, and captured experts for the first U.S. fission bombs (Section D.14.5), the German program was even further ahead of the U.S. program.

- The German nuclear program accomplished as much as it did despite the tremendous handicaps and setbacks of years of heavy Allied bombing, sabotage, and blockades, which the U.S. program did not have to endure.

- If the Thuringian device used a high-voltage fusion neutron source as an initiator, that was a more advanced solution than the U.S. polonium-210/beryllium initiator, and was ultimately adopted much later after the war by the United States.

- If the Thuringian device used a compact betatron as an initiator, that was also a more advanced solution than the U.S. polonium-210/beryllium initiator. The U.S. did not demonstrate a betatron neutron initiator for a fission bomb until the 1 June 1952 George test of Operation Tumbler-Snapper [https://nuclearweaponarchive.org/Usa/Tests/Tumblers.html].

- If the Thuringian device and other proposed German designs used neutrons from fusion fuel in the center to greatly "boost" the yield of the fission fuel, that was a major advance that could increase the energies of fission bombs by a factor of ~ 10 (from tens of kilotons to hundreds of kilotons). Officially, fusion boosting was first considered in the U.S. by Edward Teller in 1945 and in the Soviet Union by Andrei Sakharov in 1948, was first tested by the U.S. in 1951 and by the Soviet Union in 1953, and is commonly used in modern bombs [Goncharov 1996a, 1996b; Chuck Hansen 1988, 2007; Rhodes 1995; Sublette 2019; Wellerstein and Geist 2017].

- The Thuringian device appears to have been designed to be launched on a rocket (perhaps even the intercontinental A-9/A-10), which the United States was not prepared to do until 1958 (after help from hundreds of German-speaking scientists and engineers it had acquired). See p. 5821.

- The Thuringian device appears to have packed a full-fledged implosion design (and presumably an explosive yield to match) into a bomb with a total deployed mass less than half that of the first U.S. fission bombs (2000 kg for the Thuringian device vs. 4670 kg for Fat Man). Grothmann reported that Germany possessed tactical nuclear bombs that were even smaller. It took the United States several years to reduce the size and mass of fission bombs.

- Whereas the U.S. program relied heavily on a very inefficient and expensive gaseous diffusion process to help enrich uranium, the German program developed and employed (among other techniques) gas centrifuges, which were much more efficient and therefore subsequently became the preferred modern method. There is also evidence that the German program studied "photochemical" methods of uranium isotope enrichment, many decades before laser isotope separation was perfected in the United States.

- There is evidence that the German program developed electronuclear breeding of fission fuel (p. 3954), a technology that the United States did not seriously pursue until years after the war, and that is still of concern for nuclear weapons proliferation in the modern world.

- The German nuclear program appears to have produced and perhaps even used lithium-6 deuteride as readily storable solid fuel for producing fusion reactions in nuclear bombs (Section D.9), as an alternative to the much more troublesome cryogenic deuterium and tritium. Officially, lithium-6 deuteride was first considered in the United States by Edward Teller in 1947 and in the Soviet Union by Vitaly Ginzberg in 1949, was first tested by the United States in 1954, and is commonly used in modern H bombs [Goncharov 1996a, 1996b; Chuck Hansen 1988, 2007; Rhodes 1995; Sublette 2019; Wellerstein and Geist 2017].

- A 1948 U.S. intelligence document stated that Austrian and German scientists such as Josef Schintlmeister had produced and identified transuranic elements through element 104; if true, that is a feat that was not accomplished until 1969 in the United States (p. 4335).

- In addition to possibly using fusion fuel to improve a fission bomb design, there is significant evidence that the German program was working on full-fledged H-bomb versions with megaton-level yields (pp. 3401 and 4271–4273 and Sections D.9 and D.15.6). German sources stated that they expected to complete a deliverable version of such a weapon later in 1945 (see p. 4367) or in early 1946 (see p. 3401). If true, that was a feat that the United States and Soviet Union did not actually accomplish until 1953–1955 (Soviet Joe-4/RDS-6s, U.S. Castle Bravo, and Soviet RDS-37).

F. Final Perspective and Recommendations

As summarized in this appendix, the very incomplete information that is currently available about the wartime German nuclear weapons program appears to best match the pattern of a large and advanced program, not the small and primitive program that has generally been depicted for the last 75+ years. Some readers may object to this claim, but historians should actively search for additional information that could help to confirm or refute this picture:

1. Any relevant records in U.S., U.K., French, Russian, or other national archives should be located, declassified, and released to the public. Even from the currently available evidence, it is abundantly clear than highly relevant documents (wartime intelligence on German nuclear tests and progress; postwar interrogations of Hans Kammler, German and Austrian nuclear scientists, and other key players; reports on postwar investigations of nuclear-related sites and submarines; etc.) remain classified and unavailable to the public. The war ended 75+ years ago, and government censorship of all those historical documents must finally end.

2. Any relevant information in personal collections (war diaries, preserved documents, photographs, etc.) should be located, authenticated, and analyzed with the other available data.

3. Thorough scientific analyses of suspected test sites should be conducted (especially using mass spectrometry, particle-induced X-ray emission, neutron activation analysis, or other highly sensitive methods; looking for ^{238}U from the tamper; and comparing data at and away from the test sites to eliminate background signals), although after 75+ years of radioactive decay and weathering, even the most diligent testing might be inconclusive.

4. Extensive and meticulous industrial archaeological digs should be conducted at sites suspected to have been involved in developing or storing nuclear materials or nuclear weapons. Even

> if much of the material at those sites had been removed by German or Allied forces, any remaining evidence could provide conclusive proof about the nature and extent of the wartime nuclear program.

Until those searches have been thoroughly conducted, historians and scientists should cease making authoritative-sounding declarations that the nuclear program was small and unsuccessful, since there is already a great deal of evidence to the contrary.

An analogous historical mystery may be the 1960s Soviet program to land a cosmonaut on the moon. Prior to the U.S. manned landing on the moon, it was widely believed that the Soviet Union was very close to achieving the same goal. Yet once the United States had achieved victory, the Soviet Union denied that it had ever even attempted a manned lunar program. Soviet denials continued for two decades, and concrete proof of a Soviet manned lunar program could not be found. Most historians ignored the Soviet program, and only a handful of authors sifted through the small amount of available evidence and speculated about the program [Oberg 1981; Phelan 2013]. In 1990, Soviet officials finally revealed the entire former program and put five of the LK manned lunar landers that had been built for it on display in various museums [Siddiqi 2000].

Similarly, for most of World War II, it was widely believed that Germany was developing a nuclear bomb and might well beat the United States to that goal. Yet once Germany was defeated, there were denials that it had ever even attempted to develop a nuclear bomb. Those denials have continued for decades and concrete proof has not been found. Most historians have ignored the German nuclear weapons program, and only a handful of authors have sifted through the small amount of available evidence and speculated about the program. Whether those authors are correct, and whether concrete proof of the program will ever be released, remains to be determined.

If the German nuclear weapons program was indeed successful, one can understand why the major countries involved would have wanted to conceal that fact at the end of World War II and the beginning of the Cold War. Germans would not want to appear guilty of additional acts for which they might be punished after the war; key German players could find much greater personal reward in offering the fruits of the nuclear program to Allied nations and remaining silent. For purposes of internal morale and external public image, Allied countries might prefer to claim that such technological accomplishments were really their own, and in any event would be highly motivated to try to protect any new weapons technologies from rival Allied nations in the incipient Cold War.

Likewise, if the German nuclear weapons program was successful, one can also understand why the major countries involved might want to preserve that secret even 75+ years later. Germans and Austrians might not want yet another Third Reich offense from their past for which they would need to apologize. Former Allied countries might not want to admit that their wartime and postwar technological prowess was not as great as they had boasted for so many years, or that that of their vanquished enemy was greater than they had claimed for so long. In any event, routine security classification rules would prevent the release of archival documents with useful details about nuclear weapons designs and production methods, no matter what their age, history, and country of origin might have been.

Yet if the German nuclear program was truly successful, on the whole it would seem far more beneficial for all countries to finally acknowledge that fact than to continue to deny it:

1. As with “truth and reconciliation commissions” in other countries, Germany and Austria could finally acknowledge and address the full extent of the Third Reich’s actions, their current citizens (who were too young to have been involved in any of those events) could have a detailed understanding of those actions and history, and these countries could move forward with that chapter fully closed, rather than still having to hide or fear further revelations in the indefinite future.

2. Carefully inspecting and cleaning up any sites involved in producing or storing nuclear materials would prevent contamination of local drinking water and farms with radioactive isotopes, heavy metals, or other toxic chemicals.

3. Elucidating all the concentration camp prisoners who died in the preparation, production, and testing of nuclear weapons would finally bring justice to what may be many thousands of currently forgotten victims of the war.

4. The media-consuming public in former Allied countries seems fascinated with and proud of their countries’ roles in World War II, so they should be extremely interested in new details about that war, and should in fact find it exciting that their victory was even more hard-won and more consequential than previously known (somewhat similar to how sports fans are more excited by especially close or high-stakes wins).

5. Everyone would gain a much better understanding of the strategic decisions made by all countries during and after the war, making more sense of events and actions which have previously not been as well explained in the history books.

6. All nations would benefit tremendously by learning exactly how such revolutionary technologies were created then, so that they could employ similar methods of innovation to create and enjoy the benefits of new revolutionary technologies in the future.

Appendix E

Advanced Creations in Aerospace Engineering

Für den Ring nimm nun auch mein Roß!	For the Ring take now my horse!
Ging sein Lauf mit mir	Though he once carried me
einst kühn durch die Lüfte,	boldly through the air—
mit mir	with me
verlor es die mächt'ge Art;	he lost all his magic powers;
über Wolken hin	above the clouds
auf blitzenden Wettern	through lightning and thunder
nicht mehr	no more
schwingt es sich mutig des Wegs.	will he brave the way.

Richard Wagner. 1874. *Götterdämmerung* [*Twilight of the Gods*]. Prologue. Brünnhilde.

As discussed in Chapter 9, a tremendous number of aerospace technologies were invented by German-speaking creators, especially shortly before and during World War II: helicopters, guided missiles, smart bombs, jet engines and jet aircraft, ejection seats, ramjets, the V-1 cruise missile, the A-4 or V-2 single-stage rocket, supersonic wind tunnels, radar stealth technology, etc. There is also thorough documentation (though regrettably too little modern public recognition) that German-speaking creators personally carried those aerospace technologies to their limits during the postwar era, with funding and support from the United States, United Kingdom, France, Soviet Union, and other countries.

However, archival documents strongly suggest that there are several areas in which aerospace technologies may have advanced significantly further in wartime Germany than has been officially acknowledged in the conventional historical narrative.

This appendix presents:

E.1. Evidence for intercontinental jet bombers.

E.2. Evidence for liquid propellant rockets larger than the A-4 or V-2.

E.3. Evidence for space planes or space shuttles.

E.4. Evidence for large solid propellant rockets and submarine-launched rockets.

E.5. Evidence for longer-term technologies for space exploration.

E.6. A physics analysis of some of the evidence for advanced jet developments.

E.7. A physics analysis of some of the evidence for advanced rocket developments.

E.8. Conclusions.

This evidence that is currently publicly available should spur much more extensive searches in archives worldwide. Further searches could uncover documentation clarifying just how far development work proceeded during the war, how those technologies were transferred to other countries after the war, and which scientists were most responsible for the wartime and postwar work.

E.1 Intercontinental Jet Bombers

[English-language histories tend to regard intercontinental jet aircraft as an invention that originated primarily during the postwar period and primarily in Allied countries. For example, Oxford's *Biographical Dictionary of Scientists* says of Frank Whittle: "British engineer and inventor of the jet engine. The developments from his original designs were used first in the Gloster Meteor at the end of World War II. Direct descendents of these engines are now the sources of power for all kinds of military and civil aircraft" [Porter 1994, pp. 721–722]. This biographical dictionary does not mention Hans von Ohain or other German-speaking inventors of jet engines and jet aircraft, apart from briefly mentioning that "the Germans had produced the Messerschmitt Me 262 slightly earlier" than the British. While the existing literature does document the German production of small, shorter-range jet aircraft such as the Me 262, it generally describes more advanced jet aircraft as projects that never progressed much beyond the design stage [e.g., Griehl 2004; Masters 1982; Myhra 1998a].

In fact, there is evidence that even very advanced jet aircraft projects such as large intercontinental jet bombers may have progressed much further in wartime Germany than has been acknowledged in the conventional historical narrative, and that in turn those projects and their creators led directly to the postwar jet aircraft programs in Allied countries:

- March–June 1944 articles in the British magazine *Flight* reported that the Luftwaffe was rapidly constructing several large airfields near Oslo, including workshops for Heinkel, which was known for designing and building new jet aircraft, and BMW, which was known for building engines for jet aircraft (p. 5190).

- On 5 January 1945, Colonel Lowell Weicker at the Headquarters of the U.S. Strategic Air Forces in Europe wrote: "Germany... is leading the world in tested jet propelled airplanes... A large part of her manufacturing facilities have gone underground and she is bending every sinew for the last stand on the Vaterland frontiers. Our Ground Armies, despite superiority in manpower and quantity of equipment, are presently engaged more in defensive than offensive fighting and, unless this state of affairs is quickly changed or the Russians actually drive through to Berlin and victory, we must face the grim expectation of fighting Germany and her new capabilities through greater 1945... The first cycle and period of the war has ended without the capitulation of Germany and with Germany leading in the development of principal new weapons and methods, which will be included in her capabilities during 1945" (p. 5336).

- Based on a 10 May 1945 U.S. interrogation of former Luftwaffe head Hermann Goering, the *New York Times* reported on 8 June 1945 that the Germans had built a prototype Messerschmitt 264 "New York" bomber with four jet engines, found at an undisclosed place in France, and were "within a few months of working out the kinks" when the war ended (pp. 5200–5202).

- On 29–30 June 1945, numerous major newspapers reported that at the end of the war, "40 giant Heinkels of a new type, with a range of 7,000 miles" had been found near Oslo at "the largest Luftwaffe field I have ever seen" according to senior British military officers. The articles reported that "German ground crews said the planes were held in readiness for missions to New York," and that the planes had been captured by the British (pp. 5197–5198).

- On 26 June 1945, Henry Fowler, Director of the Enemy Branch of the U.S. Foreign Economic Administration testified to a U.S. Senate committee: "According to recent reports from Germany, it appears that if the Germans could have held out only 6 months longer they would have been able to smash New York City with improved V-2 bombs. Only a little longer period would have been needed to bring into production the jet-propelled planes that could have reached Washington. It is not necessary here to elaborate upon the terrifying scientific discoveries which our economic and industrial intelligence is gradually uncovering as we work beneath the lid in Germany. With the memories of her new V-weapons fresh in our minds, little needs to be added except to point out that they just didn't appear out of thin air. They were the fruit of carefully organized and adequately financed research institutions in which large numbers of highly trained and specialized scientists went about their business of inventing and developing the weapons that would establish German world supremacy... Germany could rapidly set up plants for such new products because of its enormous capacity to produce machines and machine tools, and the huge supplies of machine tools that were built up in advance of need" (p. 5206).

- On 27 August 1945, Consolidated Vultee Aircraft Corporation (Convair) stated in *Life* magazine: "In a converted salt mine, our ordnance officers examined nearly complete jet-propelled heavy bombers... bombers claimed by the Germans to be capable of crashing high explosives into the industrial cities of the eastern United States and flying back again across the Atlantic. Goering himself said that the planes had been successfully test-flown and would have been in operation if Germany could have held out 3 months longer" (p. 5208).

- In his 1956 autobiography, Ernst Heinkel did not mention the 40 giant Heinkel intercontinental bombers found in Norway, perhaps due to Cold-War censorship or to avoid self-incrimination. However, he did mention that he had long been a strong proponent of jet bombers that he believed could be built quickly, that his company participated in a late-war push to build new jet aircraft that nearly came to fruition, that those aircraft were found by the Allies, that his top designer Siegried Günter had been engrossed with flying wing bomber designs, and that Günter had submitted his information on the flying wings to U.S. Army Air Forces Major Robert L. Cardenas by the end of September 1945 (p. 5220).

- According to a report apparently written by Siegried Günter and filed by Major Cardenas on 1 October 1945, Heinkel engineers had been working on four-jet-engine long-range bombers with a flying wing design before the end of the war. Günter described 26-ton and 60-ton versions of the design with intercontinental ranges (p. 5223).

- If the British captured novel German intercontinental jet bombers with oversized wings at the end of the war, the first British intercontinental jet bombers with oversized wings such as Vulcan (1957) may be based on those German aircraft (p. 5226).

- Several different turbofan and turboprop engines with high fuel efficiencies, suitable for intercontinental bombing round trips, were under active development throughout the war, and at least some of them were built and successfully demonstrated (pp. 1746–1748, 5233–5241, 5779).

- Large numbers of German-speaking creators, designs, documentation, and prototypes for a wide range of jet engines and jet aircraft were taken to the United States and other Allied countries, directly shaping the course of postwar jet programs in those countries (pp. 1707, 5250).[1]

- German-speaking creators also developed a number of anti-radar stealth materials, coatings, configurations, and other techniques during that war that were captured and used by Allied countries after the war (p. 1234).

Today these directly German-derived technologies are represented by one third of the military "nuclear triad" (intercontinental jet bombers), as well as jet fighters, stealth aircraft, jet passenger aircraft, and gas turbines used in everything from helicopters to electric power plants.]

Behind the Lines. *Flight.* 2 March 1944 p. 230.

For Defence

From neutral sources it is reported that the Germans have started work on two new big airfields in Norway. One of these is at Eggemo[en], between Ådalen and Randsfjorden, and the other at Haslemo[en], only some 18 miles from the Swedish border.

Behind the Lines. *Flight.* 11 May 1944 p. 503.

Preparing

Only time will show the real purpose of the new chain of airfields now being established by the *Luftwaffe* in Norway. But whether for defence or offence, reports indicate a feverish activity in the expansion of existing landing facilities and the construction of new ones.

Over 300 acres of forest have been cleared to make room for the big airfield which the Germans are building at Halsemoen, Flisa, about twenty miles from the Swedish border and about fifty miles from the big air base at Gardemoen which has recently been substantially enlarged.

The work on the Haslemoen airfield started in January and large areas have been evacuated, schools and churches requisitioned, and farms devastated. The whole district has been practically destroyed. One thousand Russian prisoners and 800 Norwegian slave labourers are engaged on the work.

Only twelve miles from this airfield another temporary one is being rapidly built, and the construction of a third situated close to the Swedish border, was started at the end of last month.

Both the Fornebu airfield, near Oslo, and the Bardufors, in the county of Troms, are being expanded.

The method used for the construction of these temporary airfields on frozen ground or lakes is first to remove the snow from the ice, then cover it with a layer of sawdust which acts as an insulator, and then a layer of gravel.

Ice treated in this way—it is said—can last until midsummer, provided the weather in the spring does not become unusually warm.

In Denmark, too, the *Luftwaffe* is preparing; the Kastrup airfield is being transformed from a training to an operational base; many bombers are reported to have arrived and stocks of bombs are placed around the periphery.

On the Avedore airfield the B.M.W. have installed repair workshops for their engines, while the Heinkel concern has taken over the engine shops of the naval dockyards.

[BMW was noted for its jet engines, and Heinkel was noted for its advanced jet aircraft models. Eggemoen airfield, though not specifically named in the May 1944 article, was named in the March article and was also very important.]

Behind the Lines. *Flight.* 29 June 1944 p. 693.

Preparing

From Norway it is reported that over 300 acres of forest have been felled to make room for the big airfield which the Germans are building at Haslemoen, Flisa, about 20 miles from the Swedish frontier. The work was started in January, and large areas have been evacuated and the forests cut down. Schools and churches have been requisitioned and farms devastated. The whole district has been practically destroyed.

Norwegians in the labour service have been conscripted for this work, in the teeth of the Hague Convention, which prohibits the employment of the people of an occupied country for the military purposes of an Occupying Power.

The airfield is situated only about 50 miles from the big German airfield at Gardermoen which the Germans have substantially enlarged.

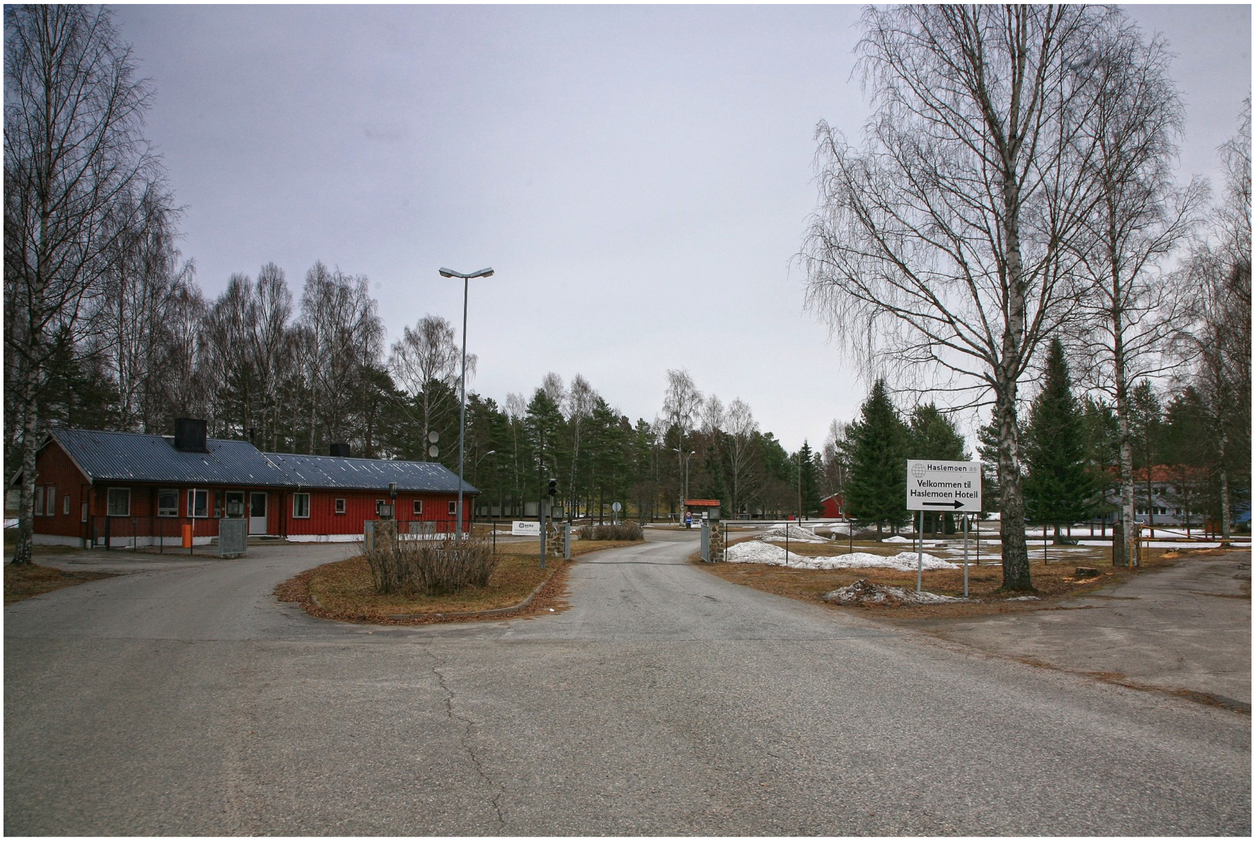

Figure E.1: Entrance to Haslemoen airfield, near the Swedish border, in 2011.

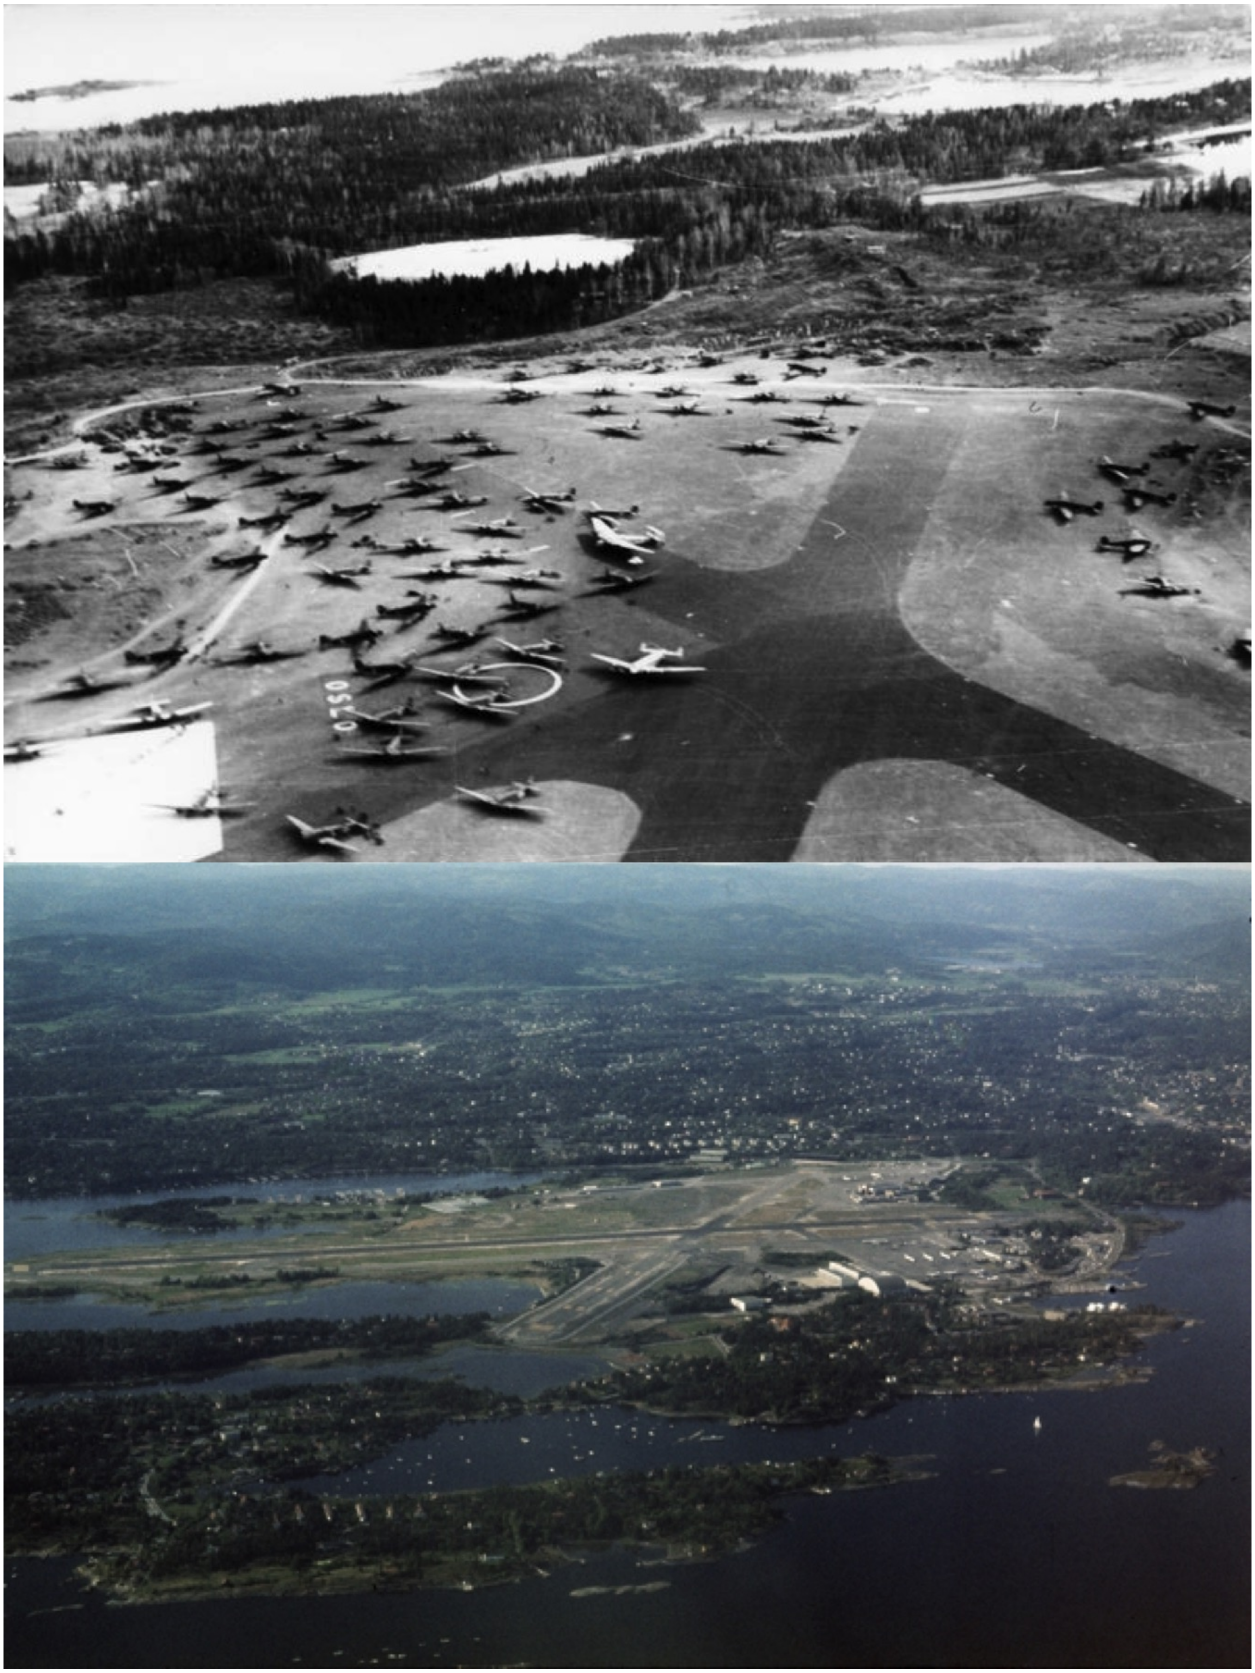

Figure E.2: Fornebu airfield, approximately 5 miles west of Oslo, in 1940 (upper) and in the late 1970s (lower).

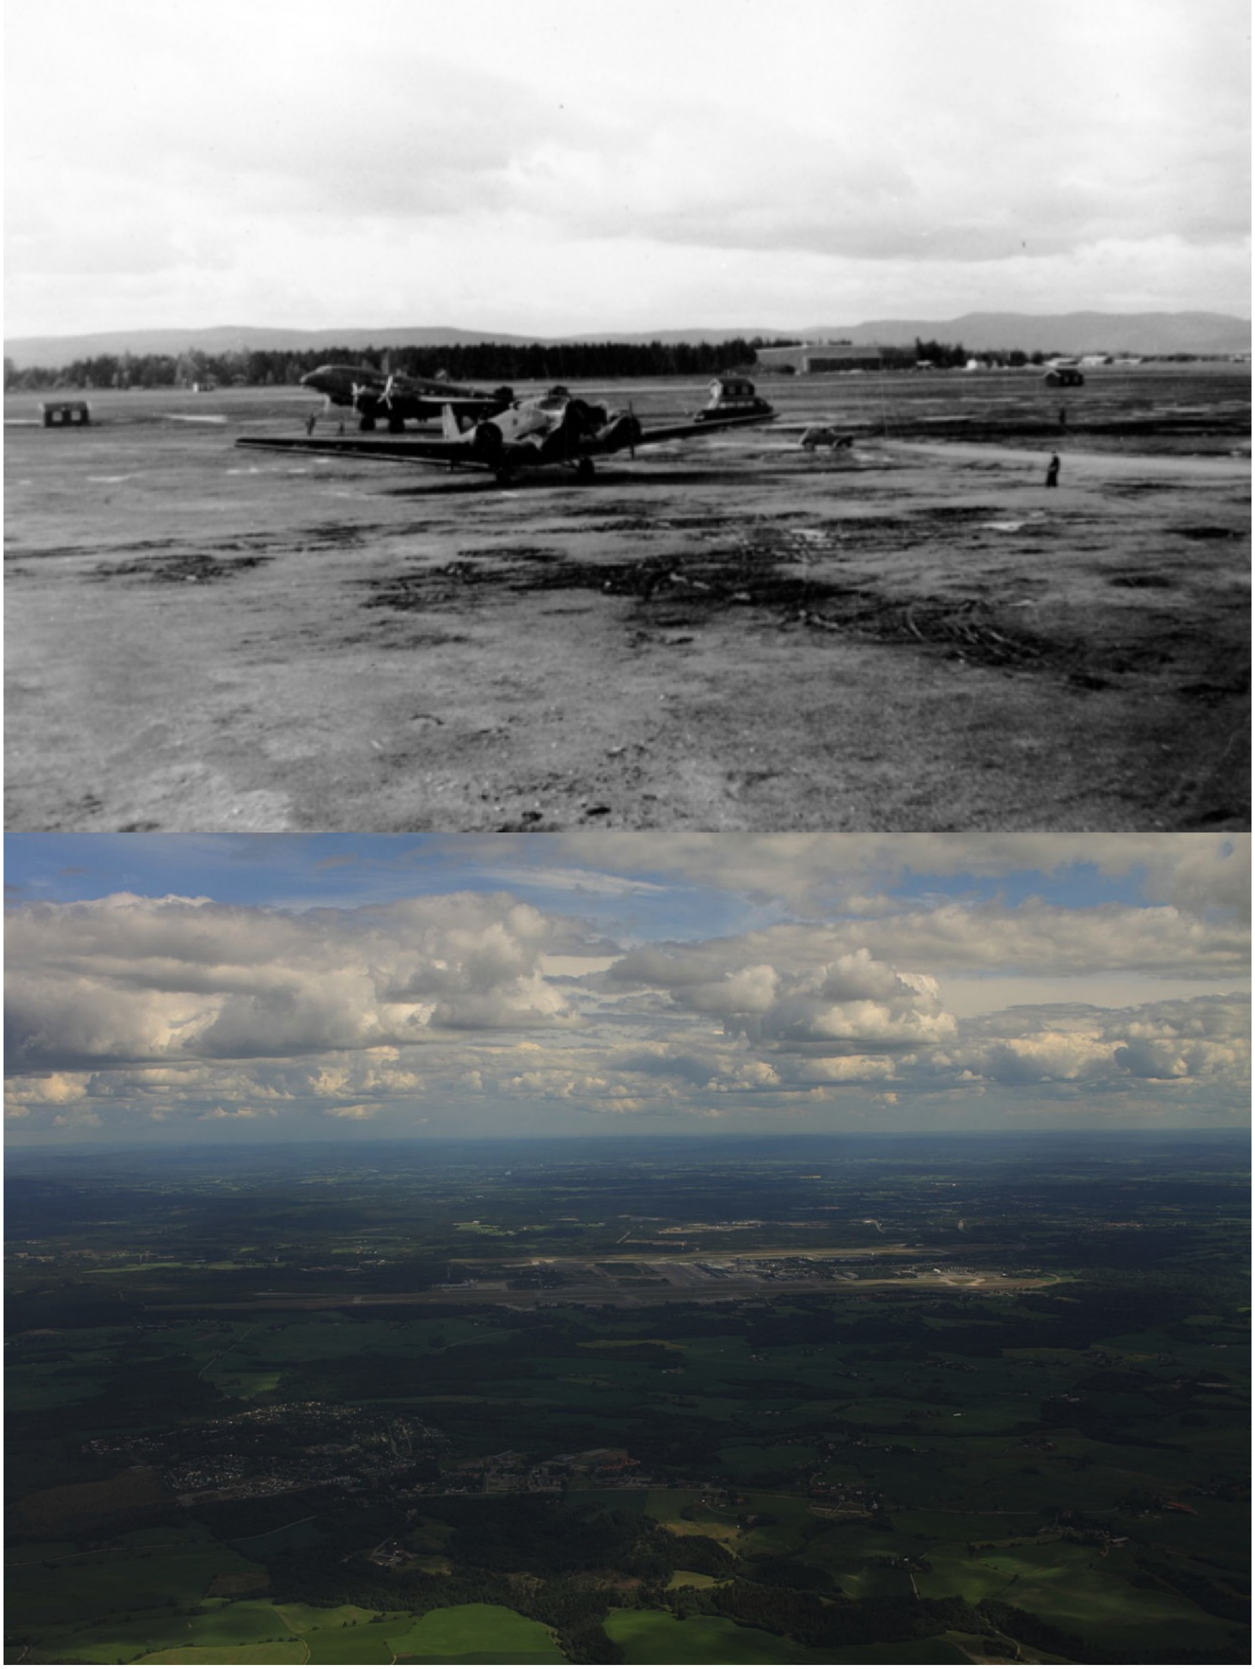

Figure E.3: Gardermoen airfield, approximately 23 miles northeast of Oslo, in 1942 (upper) and in 2010 (lower).

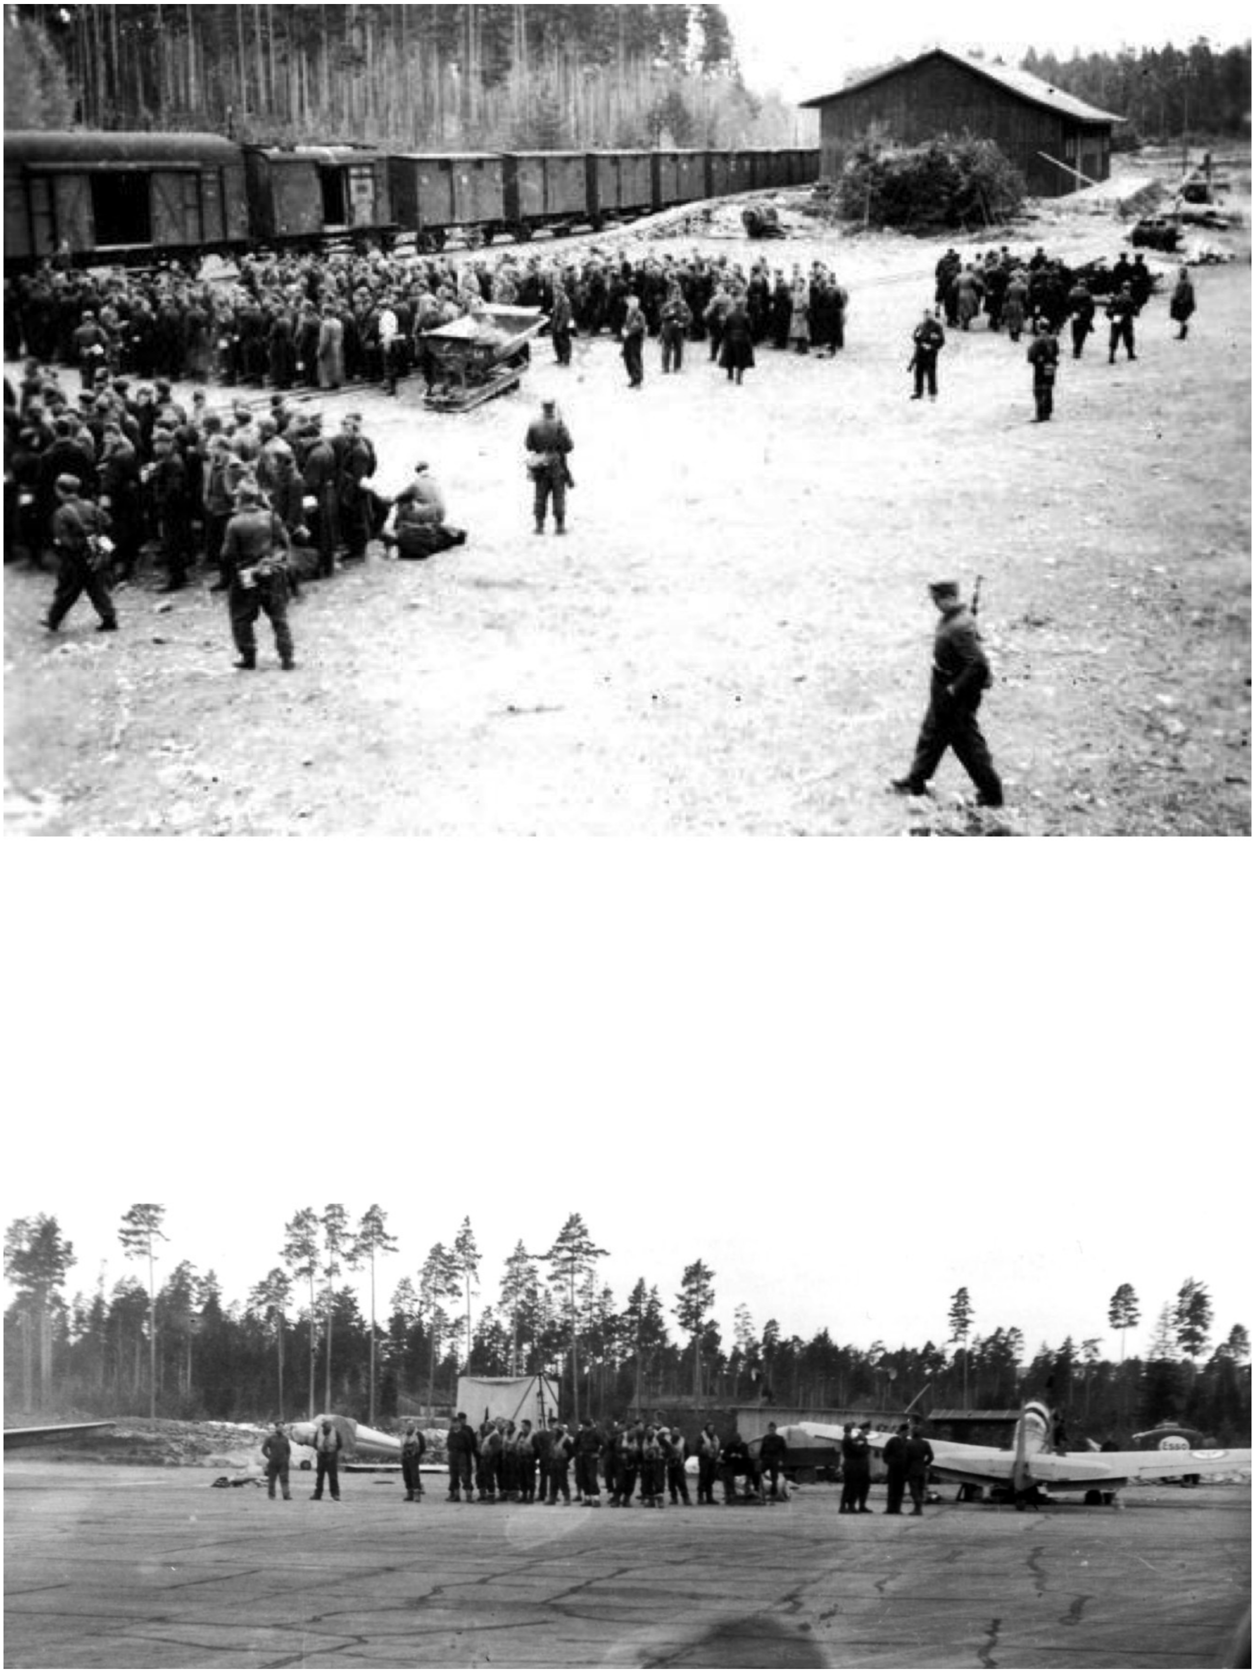

Figure E.4: Eggemoen airfield, approximately 23 miles northwest of Oslo, under construction in 1943 (upper) and operational in 1944 (lower).

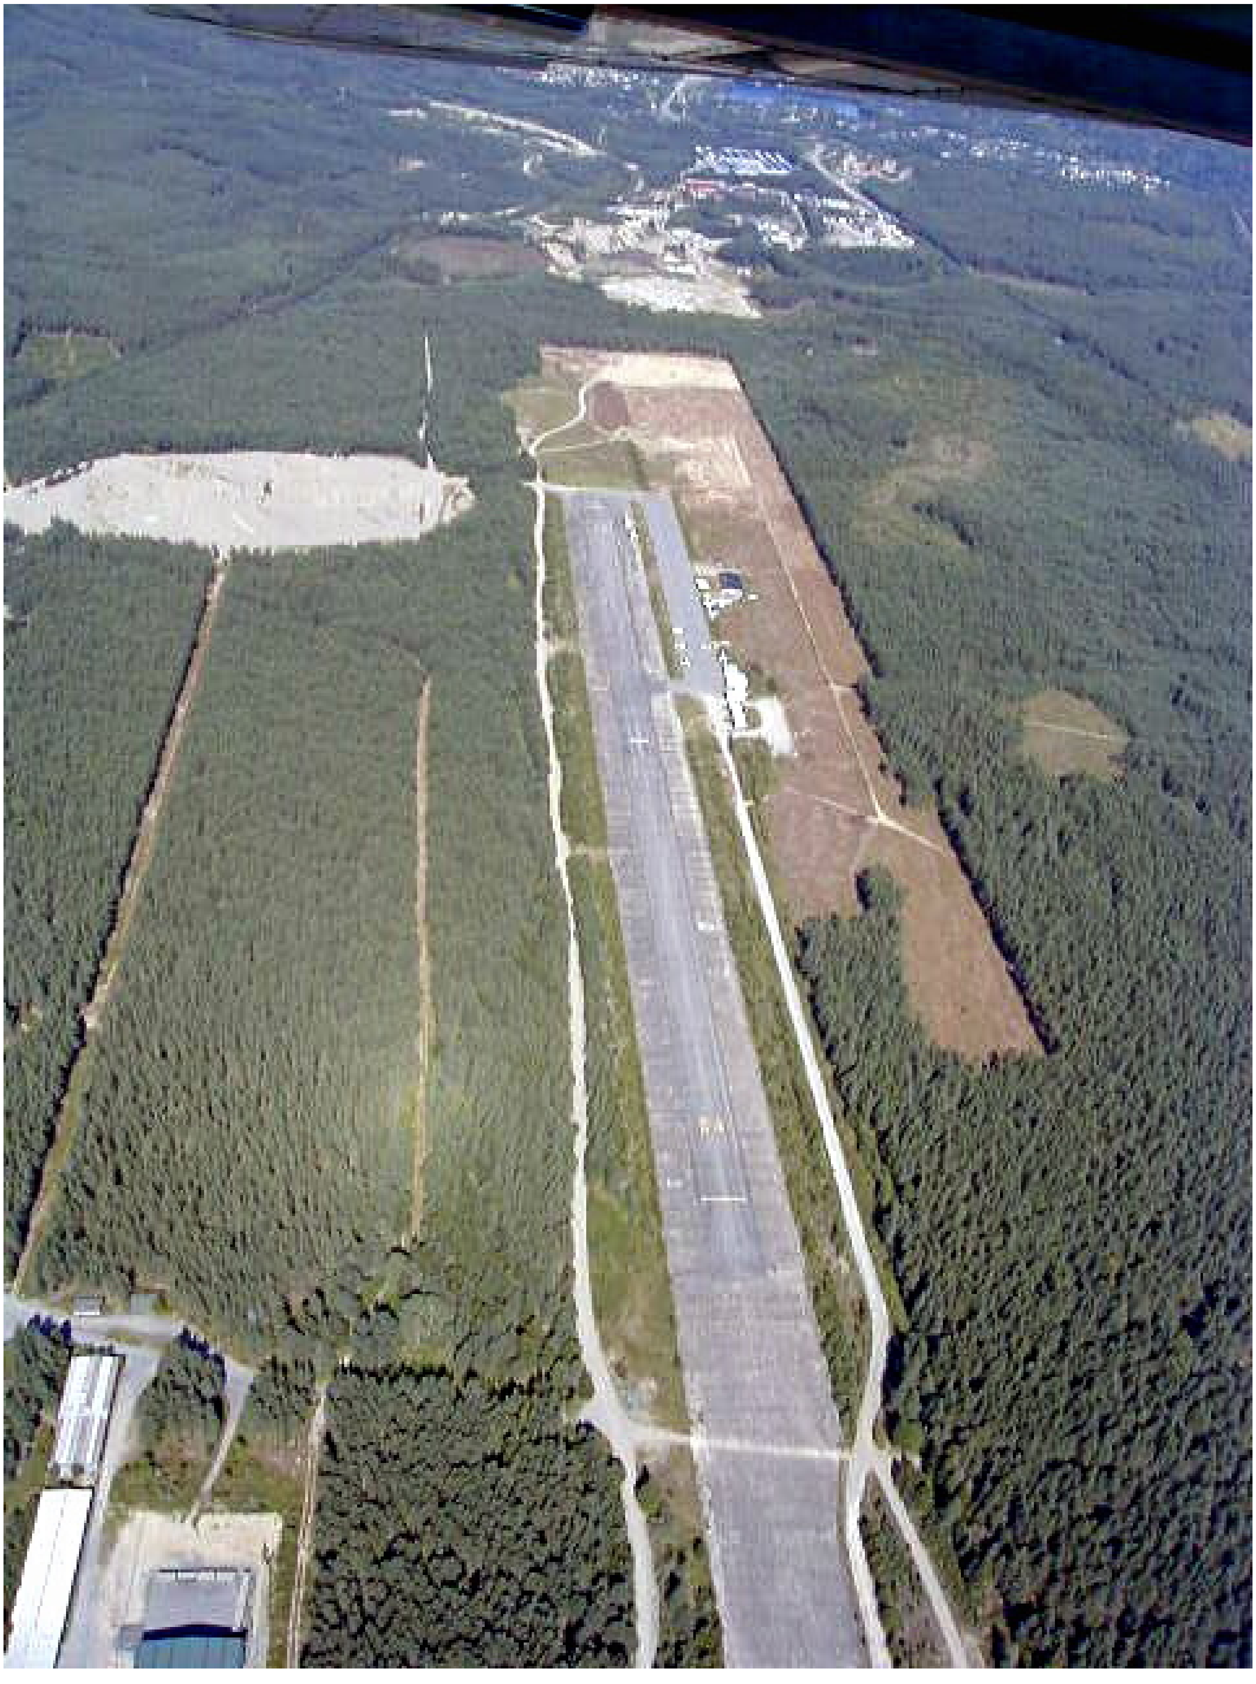

Figure E.5: Eggemoen airfield, approximately 23 miles northwest of Oslo, in 2007.

[These facts are firmly established:

- During the war, Germany built several separate airfields in southern Norway.
- Each of those airfields was massive.
- Each airfield had a remarkably large runway with the same dimensions: 1800 meters long and 60 meters wide.
- The German military placed a very high priority on finishing those airfields in 1944.
- The German military stubbornly held those airfields until V-E Day, making them an even higher priority than defending the German homeland.

The above facts are not explained in conventional histories of the war.

The above facts strongly suggest that:

- Germany expected by late 1944 or early 1945 to have huge aircraft that would need such large runways.
- Germany expected to have large numbers of those aircraft.
- Germany expected those aircraft to make war-critical missions to Allied targets—not just the United Kingdom, but also the east coast of the United States.
- Germany expected that those aircraft would be fast enough to make the trip before Allied defenses could be fully mobilized, and that at least some fraction of the aircraft could evade Allied propeller airplanes—apparently the large German aircraft were jet-propelled.
- Germany expected those aircraft to have payloads destructive enough to justify such expensive infrastructure and equipment—likely nuclear weapons, or at the very least chemical or biological weapons.

The following news articles demonstrate that such aircraft were indeed built and stationed at the Norwegian airfields.]

Planes to Bomb N. Y. Uncovered. *The Stars and Stripes* (Paris). 30 June 1945 p. 8.

Planes to Bomb N. Y. Uncovered

21st ARMY GROUP. June 29 (AP).—The Germans had “almost completed” preparations to bomb New York from a “colossal airfield” near Oslo when the war ended, RAF officers disclosed today.

“Forty giant bombers, with a 7000-mile range, were found on this base—the largest Luftwaffe field I have ever seen,” a senior officer said. “They were the new type bombers developed by Heinkel. They are now being dismantled for study. German ground crews said the planes were held in readiness for missions to New York.”

Hundreds of different type planes were taken intact on the field, cut through a pine forest about five miles from Oslo. Some of the latest model fighters, including the JU88 night fighters, equipped with intricate Radar devices to guide pilots to their target, were found.

RAF officers said they were indications that the Germans had planned a “last-ditch stand” in the area and were hoarding their newest bombers and fighters.

Bombing New York. *The West Australian* (Perth, WA). 30 June 1945 p. 7.

Bombing New York.

New Giant Heinkel.

Nazi Plan Disclosed.

London, June 29.—RAF officers have disclosed that the Germans had nearly completed preparations to bomb New York from a colossal airfield carved out of a forest 23 miles from Oslo, says a correspondent of the American Associated Press at Field Marshal Montgomery’s HQ.

A senior officer said that 40 giant Heinkels of a new type, with a range of 7,000 miles, had been found there.

German ground staff members admitted that they were being held in readiness for raids against New York.

Were Ready to Bomb N.Y. *Washington Post.* 29 June 1945.

Twenty-first Army Group Headquarters, June 28 (AP)—RAF officers said today that the Germans had nearly completed preparations for bombing New York from a “colossal airfield” near Oslo when the war ended.

“Forty giant bombers with a 7000-mile range were found on this base—the largest Luftwaffe field I have ever see,” one senior officer said.

“They were a new type bomber developed by Heinkel. They now are being dismantled for study. German ground crews said the planes were held in readiness for a mission to New York.”

[Discovery of the 40 giant Heinkel intercontinental bombers was also reported in many other newspapers worldwide, such as:

Planned N.Y. Bombing. *Chicago Daily Tribune.* 29 June 1945 p. 4.

Plan to Bomb New York Told. *Los Angeles Times.* 29 June 1945.

Nazis Nearly Bomb NY City. *Schenectady Gazette* (New York). 29 June 1945 p. 1.
[https://fultonhistory.com/newspaper%208/Schenectady%20NY%20Gazette/Schenectady%20NY%20Gazette%201945%20Grayscale/Schenectady%20NY%20Gazette%201945%20Grayscale%20-%203174.pdf]

The articles disagreed on whether the airfield was 5 miles from Oslo (the approximate distance of Fornebu) or 23 miles from Oslo (the approximate distances of both Gardermoen and Eggemoen). See Figs. E.2–E.5. The Luftwaffe used all of those airfields during the war, as well as Haslemoen (Fig. E.1). The Heinkel long-range bombers and other advanced German aircraft may have been found at all four airfields when the war ended. A combination of those or similar airfields likely would have been necessary to launch a coordinated, simultaneous, intercontinental mission by 40 large bombers and to receive the returning planes, which would have been running low on fuel after the round trip. The Luftwaffe equipped those airfields with some of the most advanced radars, approach lights, radio-guided blind landing systems, and other technology available at the time.]

Bombs Slow Down Nazi Atomic Use. *Wilmington Morning Star.* 28 September 1945, p. 8. [https://chroniclingamerica.loc.gov/lccn/sn78002169/1945-09-28/ed-1/seq-8/]

Washington, Sept. 27.—(AP)—A report by Maj. Alexander De Seversky that Allied strategic bombing of Germany may have prevented the Nazis from being the first to use atomic bombs was released today by the War Department.

De Seversky, aircraft designer and aviation writer, returned recently from Europe where he had gone as a special consultant to the Secretary of War to appraise the use of air power.

His report said that the Germans were far advanced in the aerodynamics of high speed flying, jet propulsion, the study of ballistics, rocket projectiles and synthetic fuels. He added that the German jet design was more efficient than ours.

"Moreover, there are indications that German science had made great advances in atomic power research," Seversky said. "If our strategic bombardment had not nipped enemy atomic research in the bud, the Germans might have succeeded in winning the race for the atomic bomb."

(While the De Seversky report did not detail where the air attacks on the German atomic bomb efforts occurred, the Allied air forces paid attention to German installations in Norway and islands in the Baltic sea.)

De Seversky was critical of some of the equipment used by the American Air Forces in the European war. He declared that the United States fought the war "largely with a bomber more than 10 years old in basic design."

Discussing bombsights, Seversky asserted that "I am constrained to say that there has been some gross exaggeration about the allegedly miraculous powers of our sighting devices."

Nazis Nearly Beat Allies to Atom Bomb Secret. Examiner (Launceston, Tasmania). 29 September 1945, p. 1. [https://trove.nla.gov.au/newspaper/article/91945338]

WASHINGTON (A.A.P.)—Major de Seversky, world famous aviation figure and special consultant to the Secretary for War, has reported after a five months' inspection of Europe, that German scientists might have beaten the Allies to a solution of the atomic power riddle if unrelenting Allied airpower had not interfered with their research.

De Seversky, who is at present in the Pacific, declared that the Germans were achieving sensational developments when the Reich fell. The U.S. should bring German scientists to America and make them complete their experiments for America's benefit.

The American air force must be prepared to jettison all its present equipment because, due to the advent of jet propulsion and the faster-than-sound era in aircraft design, it would be totally obsolete within 10 years.

De Seversky interrogated German military leaders, scientists and officials, including Goering. and also key figures in Britain, France, Sweden and Switzerland. He said the Germans excelled in high-speed flying research, jet propulsion, ballistics, and synthetic fuels. Their jet design was more efficient than America's.

Interrogation of Reich Marshall Hermann Goering. 10 May 1945. [Cornell University Donovan Archive]

(Because General Patch is personally responsible for the safe custody of the prisoner, it was necessary for General Spaatz' party to go from Headquarters Ninth Air Force to Headquarters Seventh U.S. Army). [...]

Interpreter provided by the Seventh Army.

Those present were:

Reich Marshal Hermann Goering.
General Spaatz, CG, USSTAF.
Lt. Gen. Patch (part of the time), CG, 7th Army.
Lt. Gen. Vandenberg, CG, Ninth Air Force.
Brig. Gen. E. P. Curtis, C/S, USSTAF.
Brig. Gen. Paul Barcus.
Major Alexander de Seversky, Special Consultant to Secretary of War.
Dr. Bruce Hopper, Historian, USSTAF.

SPAATZ: Would you tell us something of the organization of the Luftwaffe and the plans, especially the factors which went into the non-fulfillment of those plans?

GOERING: In the early years when I had supreme command of the Luftwaffe, I had definite plans, but in 1940 Hitler began to interfere, taking air fleets away from our planned operations. That was the beginning of the breakdown of the Luftwaffe efficiency. [...]

SPAATZ: Did the jet airplane really have a chance to win against us?

GOERING: Yes, I am still convinced, if we had only four to five months more time. Our underground installations were practically all ready. The factory at Kahla had a capacity of 1000 to 1200 jet airplanes a month. Now with 5000 to 6000 jets the outcome would have been different.

VANDENBERG: But could you train sufficient jet pilots, considering your shortage of oil?

GOERING: Yes, we would have had underground factories for oil, producing a sufficient quantity for the jets. The transition to jets was very easy in training. The jet pilot output was always ahead of the jet aircraft production.

SPAATZ: Could Germany have been defeated by air power alone, using England as a base, without invasion?

GOERING: No, because German industry was going underground, and our counter measures could have kept pace with your bombing. [...]

GOERING: We had too few long-range airplanes and then, later, when you got to Algiers the airfields in Italy were inadequate. You have no idea what a bad time we had in Italy. If they had only been our enemies instead of our Allies we might have won the war. [...]

SPAATZ: Have you any knowledge of a proximity fuze?

GOERING: Yes, in three or four months there would have been production. [...]

SPAATZ: If you had to design the Luftwaffe again, what would be the first airplane you would develop?

GOERING: The jet fighter and then the jet bomber. The problem of speed has been solved. It is now a question of fuel. The jet fighter takes too much. The jet bomber, ME 264, designed to go to America and back, awaited only the final solution of the fuel consumption problem. I might add that according to my view the future airplane is one without fuselage (flying wing) equipped with turbine in combination with the jet and propeller.

SEVERSKY: In view of your diminishing manufacturing resources, who made the decision to divert a large portion of your national effort to manufacture of V-1 and V-2 weapons instead of building up the Luftwaffe?

GOERING: Well, there was great confusion of thought in Germany. Prior to the invasion the V-1 would have been effective. After the invasion our effort should have been concentrated on the ME 262 (jet). The decision on the V-2 project was made at higher headquarters. [...]

SPAATZ: Did you have a three-inch gun for the jet?

GOERING: The 5.5 centimeter machine gun, only now going into production, would have made a great difference in the jet. While waiting for that we used the 5.5 centimeter rocket. You might find around Germany some jet airplanes equipped with anti-tank guns. Don't blame me for such monstrosities. This was done on the explicit orders of the Fuehrer. Hitler knew nothing about the air. He may have known something about the Army or Navy, but absolutely nothing about the air. He even considered the ME 262 to be a bomber; and he insisted it should be called a bomber.

SEVERSKY: I know that four-engine Focke-Wulf planes were in production in 1939. When you found after the Battle of Britain that your planes did not have sufficient fire power and bombing power, why didn't you concentrate on these four-engine planes as a heavy bomber?

GOERING: Instead of that, we were developing the HE 177 and tried to develop the ME 264 which was designed to go to America and return. We did use the Focke-Wulf against shipping from Norway. Because our production capacity was not so great as that of America we could not produce quickly everything we needed. Moreover, our plants were subject to constant bombing so that it was difficult to carry out our plans for heavy bomber production.

SEVERSKY: The reason why I asked the previous question was because I wanted to establish whether you failed to build the big bombers because you did not believe in strategic air power or because your productive capacity was restricted to the production of tactical aircraft for the Russian campaign.

GOERING: No, I always believed in strategic use of air power. I built the Luftwaffe as the finest bomber fleet, only to see it wasted on Stalingrad. My beautiful bomber fleet was used up in transporting munitions and supplies to the army of 200,000 at Stalingrad. I always was against the Russian campaign.

New York Bomber Built in Germany. *New York Times.* 8 June 1945.

New York Bomber Built in Germany.

De Seversky Says Principal Bar to Use Was Its High Rate of Fuel Consumption

The Germans planned to bomb New York and other eastern American ports and, according to Hermann Goering, were within a few months of working out the kinks in a jet-propelled plane that would do it, Maj. Alexander P. de Seversky, airplane designer and airpower advocate, said today.

Major de Seversky, World War I commander of the Russian Navy's Baltic fighter plane force, has been touring Germany as a special air consultant to Secretary of War Henry L. Stimson. He interviewed Goering with Gen. Carl A. Spaatz right after Goering was captured at Augsburg.

[...] The Germans' "New York" bomber, a prototype of which was found at an undisclosed place in France, was a Messerschmitt 264. It had four engines with jet propulsion for high altitudes, Major de Seversky said. The Germans started working on it before the war, designing it to cross the Atlantic and return nonstop with two or three tons of bombs. The only obstacle to its introduction was its big fuel consumption, but this, Goering asserted, the Germans had expected to solve in a few months.

[The intercontinental jet bomber described in the Goering interrogation and the article above was built by Messerschmitt and found in France. It was probably similar to, but should not be confused with, the intercontinental bombers described in the previous articles, which were built by Heinkel and found in Norway.]

Chicago Daily Tribune 1945-04-13 p. 9. German 'Flying Wing' Factory Found by Yanks. 718 M.P.H. Claimed; Plane Tailless.

GOETTINGEN, Germany, April 9 [Delayed]—A factory in which the Germans had been experimenting with a "flying wing," a super-powerful plane without fuselage or tail, has been overrun by American infantry. Both bomber and fighter types had been produced, with one to six engines. Later models were jet propelled.

Eight German technicians who had been left behind said they had flown the flying wings and found them much more maneuverable and of greater stability than conventional type planes.

One model was said to have a speed of 625 miles an hour at an altitude of 3,280 feet and 718 miles an hour at 4,600 feet. The plane's ceiling is about 52,500 feet, with a climbing rate of 65.6 feet a second. Its flying radius was reported at 937 miles.

This plane was designed to carry two bombs under the wings. [...]

[For another report of a similar six-jet-engine flying-wing bomber, see pp. 5227–5231. Note that the demonstrated airspeed reported above is in the high subsonic range. For jet engines that were optimized to operate at such airspeeds and were successfully tested in 1943, see pp. 5233–5241.]

AMEMBASSY

LUMMY.

Hart adds following details on V-3: Capture of Watten and flooding of Walcheren has played out V-2. Atom splitting explosive and frozen blitz considered diversions by industrialists acquainted with German industry. V-3 also known as cistern plane considered the real thing and estimated that a third of Luftwaffe productive capacity devoted to it. Probably two engined long range bomber but some four engined and considerable proportion jet-propelled. Experiments conducted on Leuneberger Heide near Hambrug and is now in mass production. About 2000 to be produced. Also reports that Germans are distributing gasmasks with new energy and putting new filters on old ones.

PW Intelligence Bulletin No 1/34, 5 February 1945. [AFHRA folder 506.61951 Nos. 1/19–1/35 26 Dec 1944–7 Feb 1945, IRIS 207524; AFHRA A5185 frame 481; also NARA RG 165, Entry NM84-79, Box 1915]

11. Experimental Aircraft

PW heard in 1942 when he was working as a camera man at the aircraft testing field RECHLIN (Mecklenburg) that a new type of plane was being designed which could retract its wings during flight and thereby increase its speed considerably.

PW saw the plane in flight in Feb 44 and describes it as a two (4) motor transport plane, similar to the US C47. PW heard from mechanics that the plane was designed to fly bombing missions to the US, it can carry a load of 3,000 to 4,000 kg. The speed is supposed to be 700 to 800 km per hr. The two propellers are connected to two in-line 16 cylinder engines each.

According to PW the experimental flights were very successful but the plane is not being mass-produced as yet.

PW Intelligence Bulletin No 1/34

10. 20 July 44 (Continued)

They had been arrested by a group of AHA officers led by Obst i G VON DER HEYDE, Obst FLIESSBACH, Maj in G KUBAN, and the AHA Ib, who had turned against OLBRICHT. Other conspirators personally known to PW were Obslt i G BERNARDIS, Maj i G HAYESSEN, Obslt VON DER LANCKEN (hanged), Obslt d Res GRAF VON DER SCHULENBURG, Hptm d Res KAISER, Maj THOMA, Gen VON HASE (hanged), Obst i G VON FREYTAG LOHRINGHOVEN (formerly Ic with Army Group Süd, now Amt Ausland Abwehr), Dr KIEP (former Consul General in NEW YORK, executed after he was denounced by a BERLIN physician, Dr RECKZE), and Ambassador VON HASSEL.

PW saw Dr GÖRDELER, Gen STIEFF, Obslt i G KLAMROTH, Maj i G KUHN, and Gen d Art LINDEMANN visit Gen OLBRICHT's office. Others who were involved, but not known to PW psersonally, were obst i G FREIHERR VON RÖNNE (OKH, Fremde Heere West), Gen VON STÜLPNAGEL, GRAF DOHNA, GRAF LEHNDORF, Obst i G SANDROSZINSKI (Ia, Befehlshaber des Ers Heeres), Gen VON PFUHLSTEIN (Div Brandenburg), Gen CRAMER (PW, exchanged from ENGLAND, May/June 44), Ambassador GRAF VON DER SCHULENBURG, Hptm d Res SCHOLZ-BABISCH (Generalkommando BRESLAU), GRAF LYNAR (Adjutant to WITZLEBEN), GRAF HARDENBERG (Adjutant to BOCK), Obst i G MEICHNER (Wehrmachts Führungsstab, executed. His father, Konsistorialrat in WITTENBERG, was under arrest as of Nov.), Gen Obst ZEITZLER's adjutant, and the Ia of the Kommandantur, BERLIN.

The fate of Gen Obst FROMM was not clear. Although he shot Gen Obst BECK personally in an opportune, last minute change of heart, he was still under arrest late in Nov 44.

PW visited the AHA on 22 July and saw 2 SS guards with MPs in front of every door. Patrols of the BERLIN guard Bn roamed the corridors. The offices of the executed officers were searched. The atmosphere was strained.

The hanging of Feld Marschall VON WITZLEBEN, Gen Obst HÖPNER, Gen VON HASE etc in PLÖTZENSEE prison was filmed by the UFA on HITLER's orders.

OLBRICHT was succeeded by Gen d Art MAINER.

Testimony of Henry H. Fowler, Director, Enemy Branch, Foreign Economic Administration. *Elimination of German Resources for War. Hearings Before a Subcommittee of the Committee on Military Affairs, United States Senate, Seventy-Ninth Congress, First Session, Pursuant to S. Res. 107 (78th Congress) and S. Res. 46 (79th Congress) Authorizing a Study of War Mobilization Problems. Part 3: Testimony of Foreign Economic Administration and Materials on German Penetration of European Industry.* Washington, DC: U.S. Government Printing Office. 26 June 1945.) p. 162. [**https://www.economicsvoodoo.com/wp-content/uploads/Elimination-of-German-Resources-for-War-Hearing-1945-Part-3-German-Infiltration-of-European-Industry-mas-0015.pdf**]

In assessing these bare bones of Germany's industrial war potential certain other less tangible, but none the less important, aspects of her economic base for aggression should be appraised. These include her amazing technical ability to produce new weapons as a result of technological invention, her vast pool of skilled workmen and highly trained scientists, the existence abroad of extensive economic assets and activities, and finally, a highly integrated organization and control of her economy. Each of these aspects of Germany's base for aggression deserves a brief reappraisal as of today.

Ability to produce new weapons and products.—According to recent reports from Germany, it appears that if the Germans could have held out only 6 months longer they would have been able to smash New York City with improved V-2 bombs.

Only a little longer period would have been needed to bring into production the jet-propelled planes that could have reached Washington.

It is not necessary here to elaborate upon the terrifying scientific discoveries which our economic and industrial intelligence is gradually uncovering as we work beneath the lid in Germany. With the memories of her new V-weapons fresh in our minds, little needs to be added except to point out that they just didn't appear out of thin air. They were the fruit of carefully organized and adequately financed research institutions in which large numbers of highly trained and specialized scientists went about their business of inventing and developing the weapons that would establish German world supremacy. The results they achieved and would still achieve if opportunities are provided, spring from the existence of a laboratory here and pilot plant there and a research institution in another place. These institutions and these scientists are still on hand ready to do business for a new Germany when the break comes. Nor will their ideas and inventions be fruitless because of a lack of German capacity to translate them into mass production.

Germany could rapidly set up plants for such new products because of its enormous capacity to produce machines and machine tools, and the huge supplies of machine tools that were built up in advance of need. The plants the victors so innocently permitted to operate after the last war to turn out agricultural, construction, and textile machinery for the devastated regions of Europe were expanded and re-equipped to supply German factories to meet the needs of the war of 1939—already being planned when the armistice of 1918 was signed.

German economic assets and activities outside Germany.—One of the most important bases for German aggression consists of the properties owned or controlled by Germans, which are located outside the physical borders of the country. Coupled with these properties and based upon them, there are a wide variety of economic activities which act as transmission lines for the achievement of German economic and political objectives.

Consolidated Vultee Aircraft Corporation (Convair). 1945. ...By the Skin of Our Teeth. *Life* (27 August) 19:9:2–3.

...by the Skin of our Teeth

Several times during the European phase of this war, victory was almost within Germany's grasp... on land, on the sea, or in the air.

Above all, knowing the vital importance of air supremacy, the Nazis tried time and again to wrest it back from the Allies.

And they almost succeeded.

Time ran out

Especially in the last months of the war, our margin of safety was slimmer than most of us suspected.

Just how slim it was is known best to certain American military experts who have since inspected some of Germany's underground research laboratories and war plants.

Here they saw secret weapons in various stages of development... weapons which might conceivably have turned the trick for the Nazis if they could have used them boldly in a last desperate gamble.

Some of these things can now be revealed. Others cannot—yet.

In one plant, the U.S. Army officers found partially assembled jet fighter planes of radical new design. There were planes potentially better than anything the Allies had in combat at that time.

If time hadn't run out on the Germans, quantities of these jet planes might have changed the balance of air power in their favor.

In a V rocket plant, burrowed 800 feet deep in limestone rock, our technicians found blueprints for a fearful V bomb with an estimated range of 3000 miles.

"We planned to destroy New York and other American cities starting in November," said a German rocket engineer.

Target: U.S.A.

In a converted salt mine, our ordnance officers examined nearly complete jet-propelled heavy bombers... bombers claimed by the Germans to be capable of crashing high explosives into the industrial cities of the eastern United States and flying back again across the Atlantic.

Goering himself said that the planes had been successfully test-flown and would have been in operation if Germany could have held out 3 months longer.

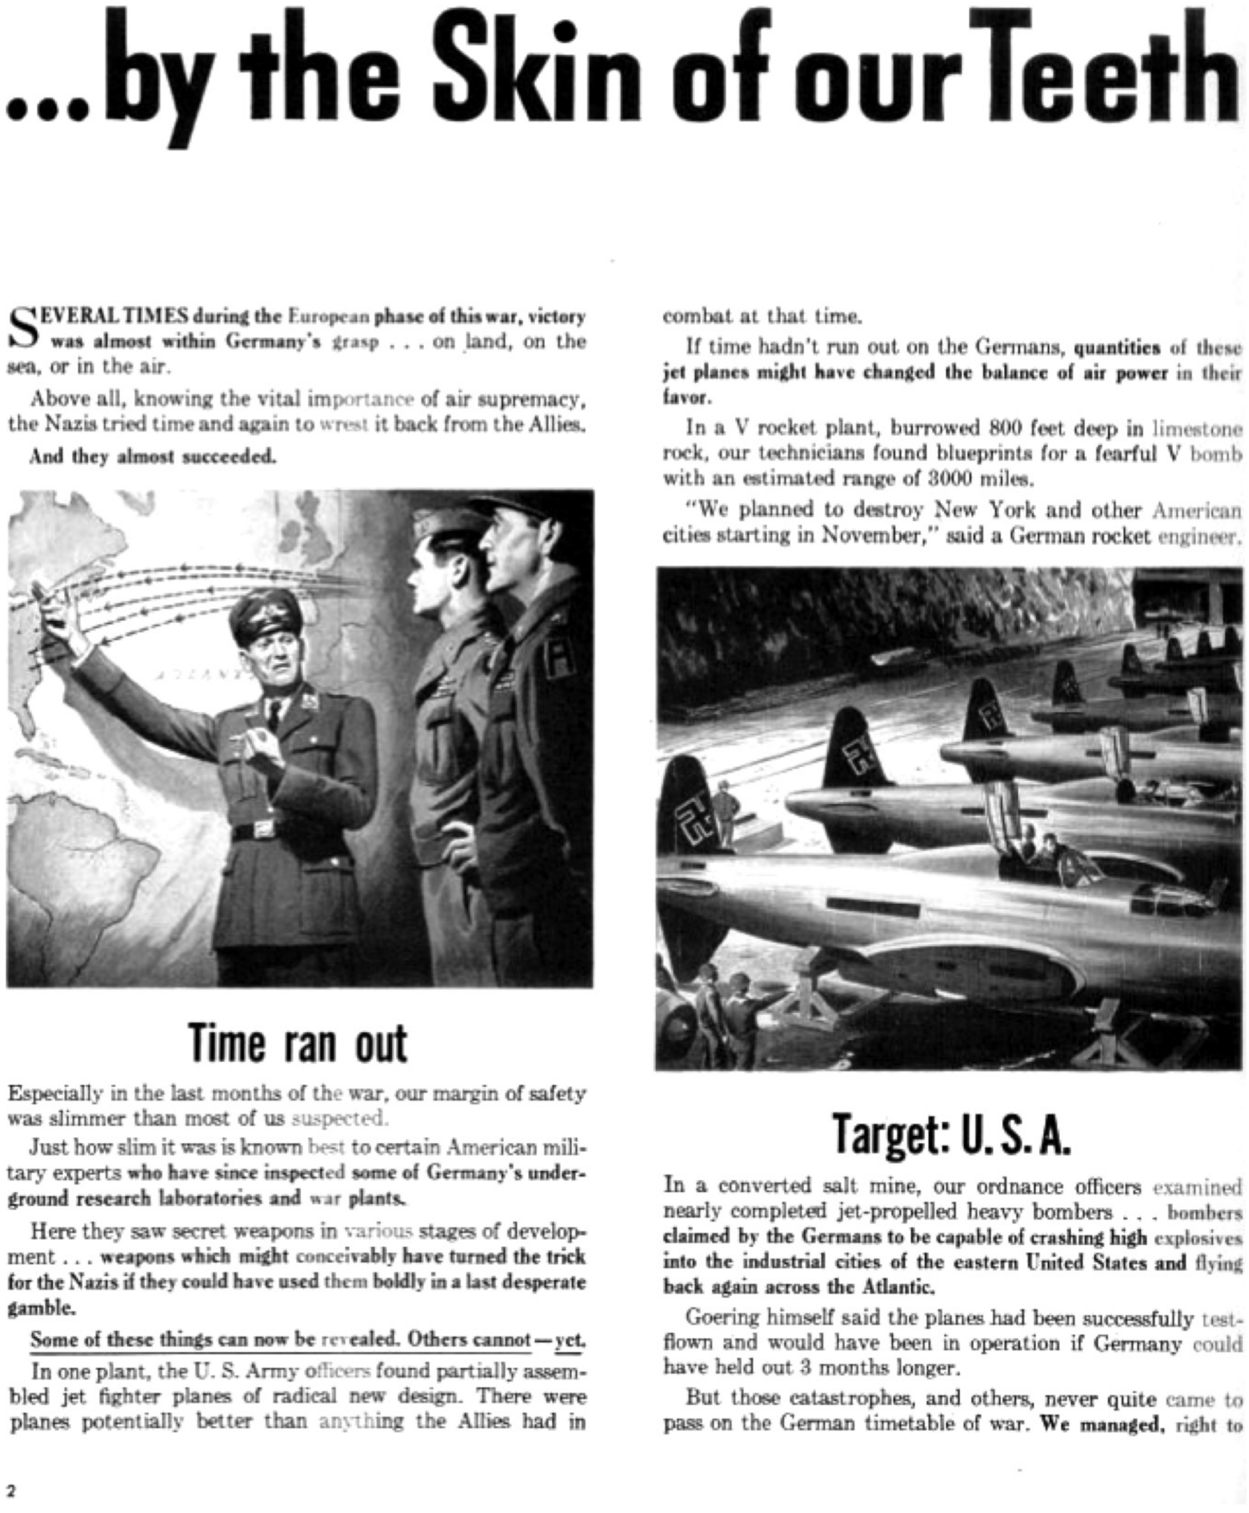
But those catastrophes, and others, never quite came to pass on the German timetable of war. We managed, right to the end, to maintain the air supremacy we had achieved... sometimes *just by the skin of our teeth.* [...]

[This two-page spread from *Life* is reproduced in full on pp. 5210–5211.

Although it was published on 27 August 1945, it was written before the 6 August 1945 bombing of Hiroshima, since it said the war with Japan was still a very serious concern. It references the end of the war in Europe and makes extensive use of postwar Allied discoveries in Europe, several of which are mentioned here but were never publicly disclosed in any other documents. Therefore the spread appears to have been written and finalized between May and July 1945.

The "nearly complete jet-propelled heavy bombers" for intercontinental missions found in the salt mine have never been publicly revealed, and appear to be distinct from the 40 intercontinental jet bombers discovered in Norway. Can documentation on this discovery be found and released? According to information given here, these long-range jet bombers had been successfully test-flown and mass produced, and would have been deployed to bomb American cities no later than the beginning of August 1945. For all of the time and money that Germany must have spent to develop such bombers, and for the long distance they would have had to travel, would their cargo really have been only conventional "high explosives," or would it have actually been atomic bombs? Note that U.S. government censorship would not have allowed any publications to write about atomic bombs prior to the public announcement of the Hiroshima bombing (and this spread was written before that time).

A German rocket engineer was specifically quoted as saying, "We planned to destroy New York and other American cities starting in November." He was not only talking about New York, but many American cities, which would have required a number of intercontinental rockets. Furthermore, he said that those cities would be "destroyed," which would have required atomic bombs and not merely one-ton conventional explosive warheads such as the V-2 rockets delivered to London. Thus this engineer who was apparently deeply involved with and knowledgeable about the German programs indicated that mass-production of both numerous intercontinental rockets and numerous atomic bombs apparently would have been completed before November 1945. That would have required mass production of both to begin well before that time, and prototype intercontinental rockets and atomic bombs to have been completed and tested even before that. From that timeline, the intercontinental rocket and atomic bomb programs must have been extremely advanced by the end of the war—they would have been far beyond the stage of just "blueprints for a fearful V bomb."]



...by the Skin of our Teeth

SEVERAL TIMES **during the European phase of this war, victory was almost within Germany's grasp** . . . on land, on the sea, or in the air.

Above all, knowing the vital importance of air supremacy, the Nazis tried time and again to wrest it back from the Allies.

And they almost succeeded.

Time ran out

Especially in the last months of the war, our margin of safety was slimmer than most of us suspected.

Just how slim it was is known best to certain American military experts **who have since inspected some of Germany's underground research laboratories and war plants.**

Here they saw secret weapons in various stages of development . . . **weapons which might conceivably have turned the trick for the Nazis if they could have used them boldly in a last desperate gamble.**

Some of these things can now be revealed. Others cannot—yet.

In one plant, the U. S. Army officers found partially assembled jet fighter planes of radical new design. There were planes potentially better than anything the Allies had in combat at that time.

If time hadn't run out on the Germans, **quantities of these jet planes might have changed the balance of air power in their favor.**

In a V rocket plant, burrowed 800 feet deep in limestone rock, our technicians found blueprints for a fearful V bomb with an estimated range of 3000 miles.

"We planned to destroy New York and other American cities starting in November," said a German rocket engineer.

Target: U. S. A.

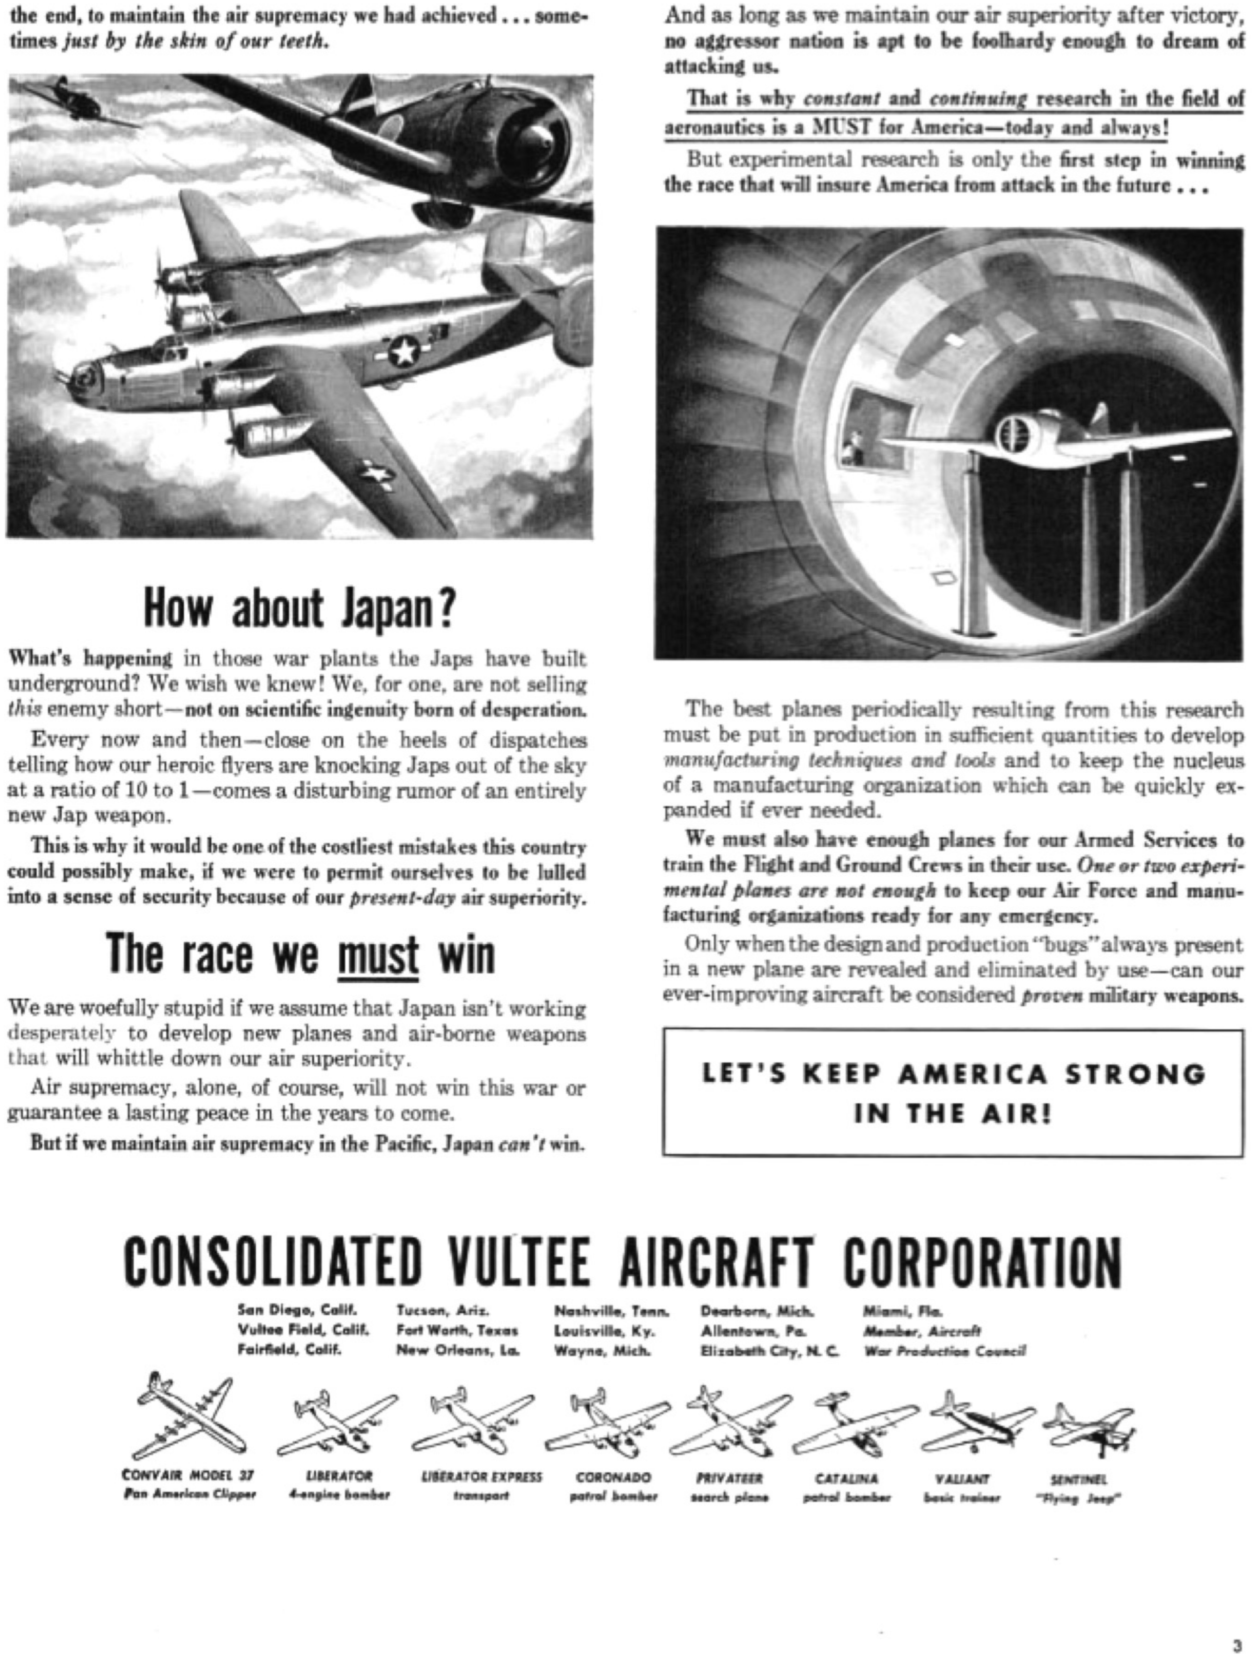
In a converted salt mine, our ordnance officers examined nearly completed jet-propelled heavy bombers . . . **bombers claimed by the Germans to be capable of crashing high explosives into the industrial cities of the eastern United States and flying back again across the Atlantic.**

Goering himself said the planes had been successfully test-flown and would have been in operation if Germany could have held out 3 months longer.

But those catastrophes, and others, never quite came to pass on the German timetable of war. **We managed,** right to

2

Figure E.8: Two-page spread from *Life*, 27 August 1945.



the end, to maintain the air supremacy we had achieved . . . sometimes *just by the skin of our teeth.*

How about Japan?

What's happening in those war plants the Japs have built underground? We wish we knew! We, for one, are not selling *this* enemy short—**not on scientific ingenuity born of desperation.**

Every now and then—close on the heels of dispatches telling how our heroic flyers are knocking Japs out of the sky at a ratio of 10 to 1—comes a disturbing rumor of an entirely new Jap weapon.

This is why it would be one of the costliest mistakes this country could possibly make, if we were to permit ourselves to be lulled into a sense of security because of our *present-day* air superiority.

The race we must win

We are woefully stupid if we assume that Japan isn't working desperately to develop new planes and air-borne weapons that will whittle down our air superiority.

Air supremacy, alone, of course, will not win this war or guarantee a lasting peace in the years to come.

But if we maintain air supremacy in the Pacific, Japan *can't* win.

And as long as we maintain our air superiority after victory, **no aggressor nation is apt to be foolhardy enough to dream of attacking us.**

That is why *constant* and *continuing* research in the field of aeronautics is a MUST for America—today and always!

But experimental research is only the **first step in winning the race that will insure America from attack in the future . . .**

The best planes periodically resulting from this research must be put in production in sufficient quantities to develop *manufacturing techniques and tools* and to keep the nucleus of a manufacturing organization which can be quickly expanded if ever needed.

We must also have enough planes for our Armed Services to train the Flight and Ground Crews in their use. *One or two experimental planes are not enough* to keep our Air Force and manufacturing organizations ready for any emergency.

Only when the design and production "bugs" always present in a new plane are revealed and eliminated by use—can our ever-improving aircraft be considered ***proven* military weapons.**

Albert Ducrocq. 1947. *Les Armes Secrètes Allemandes.* Paris: Berger-Levrault. pp. 163–164.

Les bombardiers lourds intercontinentaux Heinkel

C'est vraisemblablement à partir du mois de juin 1945 que l'Allemagne pensait attaquer le territoire américain. Notons-le: alors que la mise en action d'autres armes secrètes, comme les bombes volantes et les nouveaux avions-fusées, était littéralement imminente, cette menace contre les États-Unis doit être située à six semaines ou deux mois après la date qui marqua l'effondrement du Reich. On nous permettra de la trouver pratiquement tout aussi dangereuse, d'autant plus que les V-2 amphibies, elles aussi, auraient très bien pu transporter des bombes atomiques.

Mais les Allemands préparaient, en plus, des raids de bombardement sur l'Amérique à partir de leurs bases européennes. Ils avaient, en effet, mis en construction sur une assez vaste échelle des bombardiers géants de type Heinkel, capables de couvrir sans escale de 11.000 à 12.000 kilomètres, c'est-à-dire largement un aller et retour Europe-Amérique!

La Norvège avait été choisie comme point de concentration de ces bombardiers intercontinentaux. Les Allemands avaient aménagé près d'Oslo le plus grand aérodrome de toute la Luftwaffe. Et il n'est pas sans intérêt de noter que, le 27 avril 1945—trois jours avant la fin de la bataille de Berlin et la disparition d'Hitler—400 [sic: 40] de ces bombardiers étaient bel et bien rassemblés sur l'aérodrome en question, prêts à prendre leur envol vers l'Amérique. C'est le 21e Groupe d'armées américain [sic: U.K.] qui devait les découvrir deux semaines plus tard...

Heinkel intercontinental heavy bombers

Germany was probably thinking of attacking American territory beginning in June 1945. It should be noted that while the use of other secret weapons, such as flying bombs and new rocket planes, was literally imminent, this threat to the United States must be located six weeks or two months after the date of the collapse of the Reich. We are allowed to consider it almost as dangerous, especially since the amphibious V-2s, too, could very well have carried atomic bombs.

But the Germans were also planning bombing raids on America from their European bases. They had, in fact, built giant Heinkel-type bombers on a fairly large scale, capable of covering non-stop 11,000 to 12,000 kilometers, i.e. a round trip from Europe to America!

Norway had been chosen as a concentration point for these intercontinental bombers. The Germans had set up near Oslo the largest airfield of the Luftwaffe. And it is not without interest to note that, on April 27, 1945—three days before the end of the battle of Berlin and the demise of Hitler—400 [sic: 40] of these bombers were indeed gathered on the airfield in question, ready to take off for America. It was the 21st American [sic: actually British] Army Group that was to discover them two weeks later...

[Albert Ducrocq (1921–2001) was a French scientist and science writer who was involved in the French investigations of German science and German scientists near the end of the war and after the war. He would have had considerable first-hand knowledge about German scientific plans and capabilities, although some of his knowledge would have been second- or third-hand. His story of the Heinkel intercontinental bombers agreed with the 29/30 June 1945 articles in English-speaking newspapers, but he also included several details that were not in those stories. It is not clear where Ducrocq got those details.

Note that Ducrocq suggested that Germany possessed atomic bombs and planned to deliver them via the Heinkel bombers or other means. Note too that he mentioned “amphibious V-2s,” submarine-launched missiles that also would have been nuclear armed; see Section E.4.

For more information from Ducrocq, see pp. 5380, 5658–5659, 5666.

For independent confirmation of German plans for a nearly simultaneous nuclear attack on multiple Allied targets, see pp. 4549–4550, 4587, 4621, 4627–4665, 4679–4681, 4766, 5038, 5454–5466.]

Rudolf Lusar. 1956. *Die deutschen Waffen und Geheimwaffen des 2. Weltkrieges und ihre Weiterentwicklung.* 1st ed., Munich: J. F. Lehmanns. p. 49

Kurz vor dem Kriegsende kam Professor Heinkel noch mit einem schweren Vierstrahltriebwerk-Bomber heraus, anscheinend He-343 (?), der eine Reichweite von 11000 bis 12000 km haben sollte. Dieses Bombenflugzeug war bestimmt Amerika anzugreifen. Nach amerikanischen Berichten waren am 27. April 1945 mehrere dieser Maschinen auf einem Flugplatz bei Oslo, Norwegen, versammelt, wo sie der amerikanischen 21. Armee in die Hände gefallen sein sollen. Sie sollten im Mai den ersten Einsatz gegen New York fliegen.	Just before the end of the war, Professor Heinkel came out with a heavy four-jet engine bomber, apparently He-343 (?), which was supposed to have a range of 11,000 to 12,000 km. This bomber was destined to attack America. According to American reports, on April 27, 1945, a number of these machines were massed at an airfield near Oslo, Norway, where they were to fall into the hands of the American [sic: actually British] 21st Army. They were supposed to be flying to New York in May.

[The details provided by Lusar were very similar to those provided by Ducrocq. Did Lusar obtain his information from Ducrocq, or did Lusar and Ducrocq have other sources that provided the same information? Lusar was apparently speculating about the exact identity of the Heinkel intercontinental bomber.]

Ernst Heinkel [Heinkel 1956, pp. 236–241, 246–247; see also Myhra 1998a, pp. 156–160]

On this occasion [early 1942] I was so upset that I declared, “At the present stage of jet units I am convinced we can produce jet bombers as well as very fast fighters in an extremely short time. I cannot see why we should delay for a moment. The Ministry must form a commission to eliminate all difficulties. It’s a matter of indifference whether Junkers or BMW units [jet engines] or any other units are used. The plane can, in any case, be built by the middle of next year.”

The conference ended without result. Neither Milch nor his colleagues would decide upon the building of jets. [...]

No one will take exception to my having had my doubts about the technical soundness of the reasons for scrapping my He 280...

After the rejection of the He 280 I remained excluded until the summer of 1944 from the development of jet airplanes, which Sauer now carried on with great vigor. This development, however, remained limited chiefly to the Me 262 and the outstanding Arado reconnaissance plane Ar 234. Much time had been lost and the general situation was now so precarious that up to October, 1944, only from one to three Me 262’s appeared each month. Then for the first time Sauer’s ruthlessness and powers of organization and improvisation made themselves felt, and by the end of the war about 1,600 Me 262’s were built, under the indescribable conditions that prevailed during those last six months.

They were produced in countless factories and small workshops, both above and below ground. Because of the disorganized railroad system, road convoys had to bring the individual parts to the assembly sheds. Smaller parts were brought by courier in haversacks. It is understandable that only a few hundred of these planes actually reached the last front-line units which still remained in South Germany and were largely destroyed from the air simply because it was no longer possible to supply them with some last piece of equipment, such as a cabin canopy. German industry could not bring the two-engined Me 262 into mass production, in spite of all improvisations and efforts. Destruction by enemy bombing, shifting of plants, the flight from occupied territory and constant communications breakdowns made it impossible. [...]

When I, too, received orders at Vienna to build a light single-engined jet fighter, I realized that this was a last attempt to struggle against the inevitable. Yet the fact that I had been shut out from the revolutionary development of jet aircraft, even though I had been the first to take it up, had left such scars in me that I was eager to prove my supremacy in the field once more.

[...] Now we started to work on the last jet fighter of the German Luftwaffe in World War II. It was the He 162, misnamed “people’s fighter.”

Construction began on September 24, 1944, in Vienna. [...]

All arrangements had been made when the heavy Allied attacks on German communications started in the spring of 1945. A few weeks later, despite our efforts, there was no further possibility of achieving a regular output. On April 1, 1945, we had to close all our factories in Vienna in the face of the advancing Russian armies.

Thus ended the last great effort in the field of jet-plane building, without a single plane ever getting to the front. Most of the completed planes were destroyed in the factories or in Oranienburg, where the Lufthansa had tried to open a test-flight center, or they fell into the hands of the British, American or Russian engineers advancing with their victorious armies through Germany. [...]

After returning home on August 5, 1945, I wanted to see the situation in Jenbach with my own eyes. [...]

Stopping at Landsberg, I searched for Siegfried Günter, who had escaped there in the middle of April, 1945, and had managed to carry on a primitive office with thirty-five other employees from my design office. I found him—the most important expert on airplane structures and aerodynamics that Europe had at that time—living with his wife in a small room. He was working with ten of my people in a technical office that an American, Major Cardenas, had established on the airfield. They had tried in vain to call the attention of the American military authorities to the importance of Günter.

Günter was too modest and shy to blow his own horn. Now he was happy that Cardenas had enabled him to carry on his scientific work. This work embraced everything we had planned for the future in the way of fresh developments in jet propulsion. He was particularly engrossed with new "flying wing" types. I hoped on this visit that Günter would find a permanent outlet for his activities, either in Landsberg or in America.

I knew him. His only happiness was in scientific work and I told this to Cardenas. A few weeks later, however, at the end of September, Cardenas closed his office and flew to England. He informed Günter that a larger office was planned in Wiesbaden and that he would send for him, but he never did.

Günter remained in Landsberg until the spring of 1946, when his money ran out. During the last weeks he constantly repeated that he had no skill for anything else—he had to build airplanes. If the West didn't want him, he might have to work for the East. At that moment, I was empty-handed and could do nothing for the man who for so many years had been my closest collaborator and whose unique abilities no one could appreciate better than myself.

In the spring of 1946 he used the last of his money to go to Berlin to see his father-in-law, who kept a garage. He still hoped the Americans would send for him, and left his address in case some message should arrive, but no message came.

Instead, the Soviet special experimental unit OKB IV, in Berlin, took him on. Günter continued to work on our latest designs and was then taken to Russia, where, I am convinced, he worked on constructions that today have become a problem for the Western world.

[Ernst Heinkel did not mention the 40 giant bombers in Norway, but due to Cold War censorship and Heinkel's motivation to avoid self-incrimination, one would not expect him to. However, he did mention that he had long been a strong proponent of jet bombers that he believed could be built quickly, that his company participated in a late-war push to build new jet aircraft that nearly came to fruition, that those aircraft were found by the Allies, that his top designer Siegried Günter had been engrossed with flying wing bomber designs, and that Günter had submitted his information on the flying wings to Major Robert L. Cardenas [see Johnsen 2014, pp. 119–120] by the end of September 1945.]

Dieter Herwig and Heinz Rode. 2000. *Luftwaffe Secret Projects: Strategic Bombers 1935-1945.* 2nd ed. Hinckley, UK: Midland. p. 68:

Heinkel Projects for a Four-Jet Long-Range Bomber

According to a report which Dipl-Ing Siegfried Günter—who had been head of Heinkel's Project and Design Department in Vienna—was required to write for the US Technical Service on 1st October 1945, Heinkel engineers had been engaged on designs for four-jet long-range bombers right up until May 1945. These designs included not only aircraft of standard 'fuselage and tail' configuration, but also of flying-wing layout.

Work was concentrated particularly on one flying-wing bomber which was powered by four HeS 109-011 jet engines, each developing 1,300 kg (2,865 lb) static thrust, and which weighed 26 tons.

Another flying-wing bomber was to have been fitted with either four BMW 109-018s, each of 3,000 kg (6,612 lb) static thrust, or six Junkers Jumo 004 jet engines, each of 1,300 kg (2,865 lb) static thrust. This machine which possessed a very high wing loading, would have weighed 60 tons.

[...] Again according to Günter's report, the 60-ton flying-wing project was to have combined a 3,000 kg (6,612 lb) bomb load with a range of 28,000 km (17,388 miles).

[Can this 1 October 1945 report by Siegfried Günter be located? It appears to have been filed by Major Robert Cardenas when he left Germany.

Is this information directly related to the 40 Heinkel intercontinental bombers that were reported to have been found in Norway?

Oslo to New York is approximately 5930 km (3680 miles), or approximately 11,860 km (7360 miles) roundtrip. Oslo to Los Angeles is approximately 8570 km (5320 mi), or approximately 17,140 km (10,640 mi) roundtrip.

Are there UK or US aerial surveillance photos of the Oslo-area Luftwaffe airfields from 1944 or 1945?

Are some postwar Allied long-range jet bomber designs such as the British Valiant, Victor, and Vulcan series directly descended from these planned or completed German bombers?

Other German intercontinental jet bombers had been designed and may have been in various stages of development, testing, or production by the end of the war. [Herwig and Rode 2000; Miranda 2015; Masters 1982, especially pp. 79–80; Myhra 1998a, especially pp. 156–160; Griehl 2005, Vol. 2].]

[See pp. 5228–5231 for this document. It was released along with many other unrelated documents as part of a Freedom Of Information Act (FOIA) request.

This document was a proposal sent to the U.S. Army after World War II by a group of German aerospace engineers and pilots, including Albert Kalkert (German, 1902–1977, p. 1679) and Herbert Hintze (German, 1921–??). They offered to immediately begin building for the United States a Horten-style flying wing intercontinental bomber with 6 jet engines, various armaments, a 48-meter wingspan, an operating radius of 7,000 km (14,000 km total range round trip), and a speed of 900 km/hour ("900 Km/St." on the drawing, or 250 m/sec).

Since their offer was so specific and so immediate, was it based on an identical aircraft (or multiple aircraft) that they had already built during the war? For reports that such aircraft were actually constructed and even flown during the war, see for example p. 5202.

Note that the combined range and speed strongly suggest that the German engineers had a detailed and ready knowledge of (or access to) turbofan engines, not just the more common wartime German turbojet engines (p. 5779). In fact, a suitable turbofan engine that was specifically designed for a cruise velocity of 250 m/sec was first demonstrated in 1943–see pp. 5233–5241.]

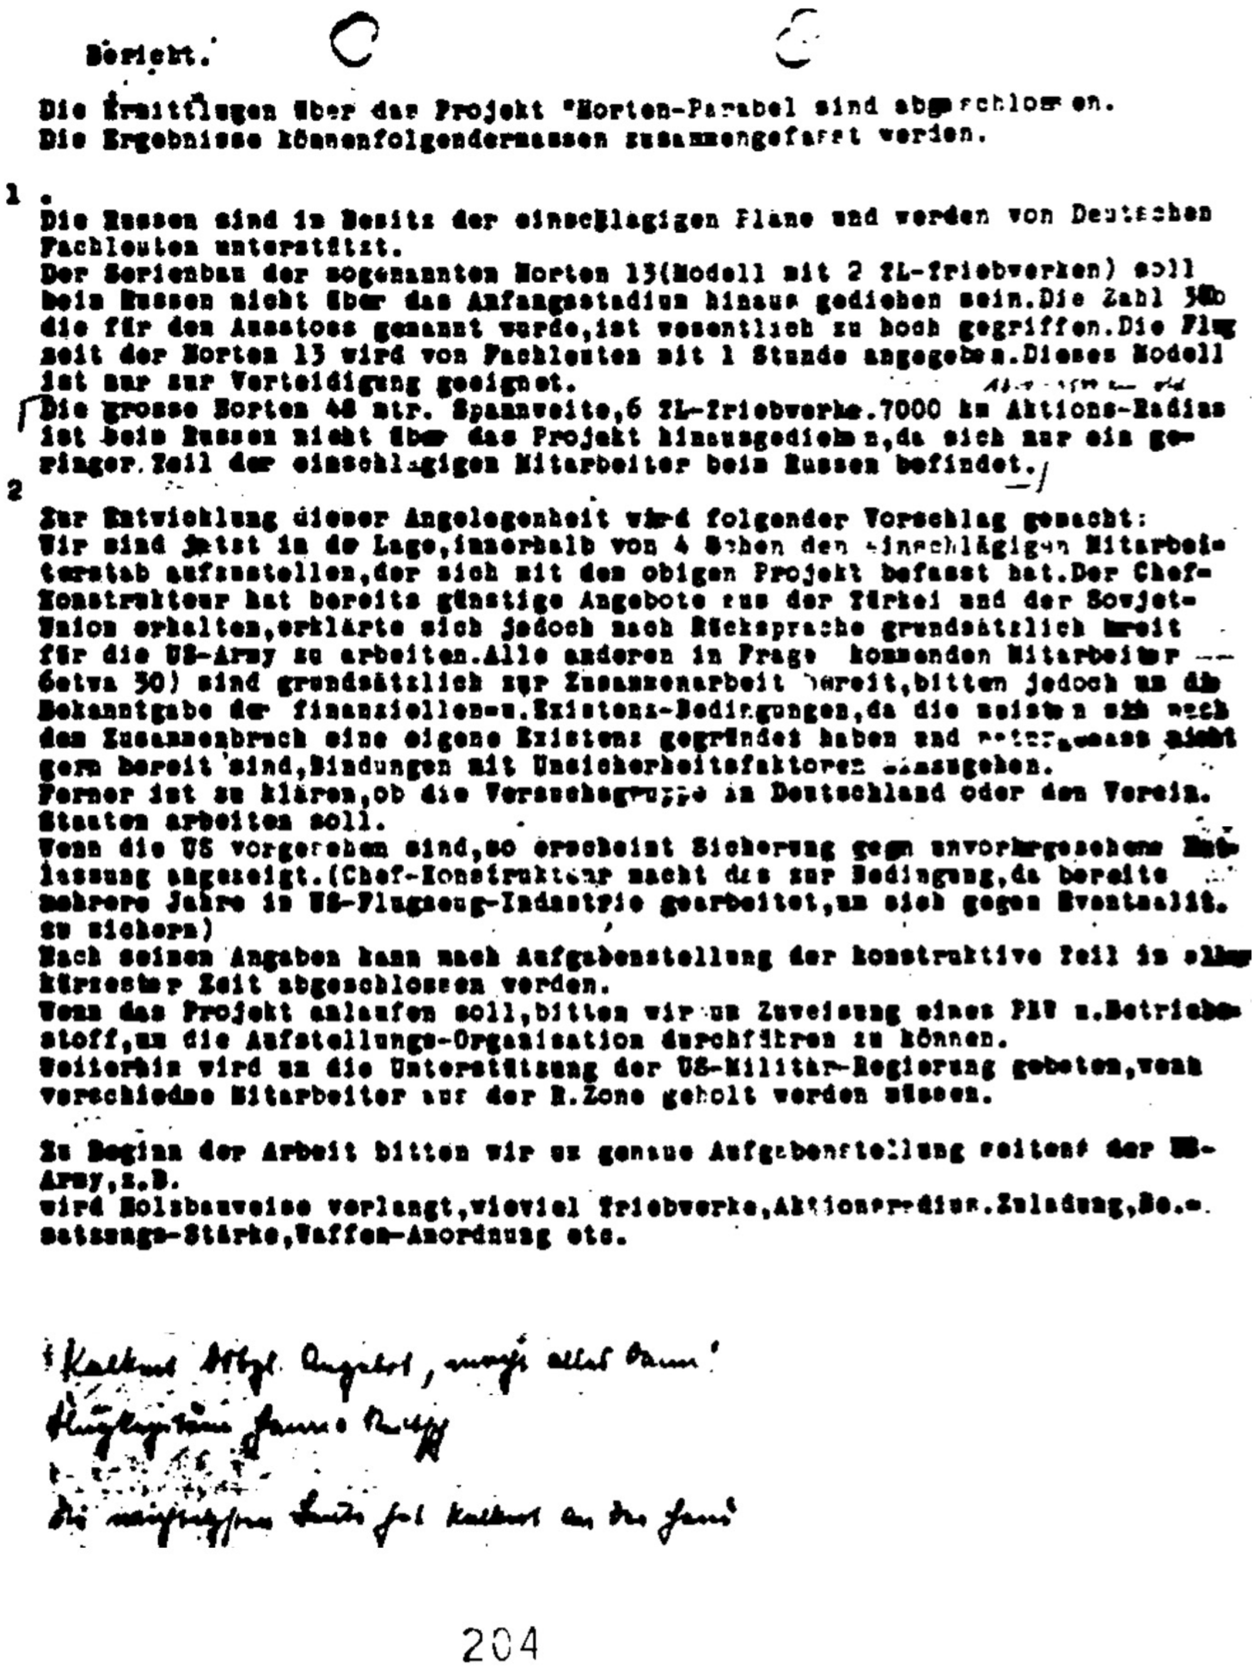
Figure E.20: After the war, a group of German aerospace engineers offered to immediately begin building for the U.S. military a 7,000-km-range (14,000-km round trip), 6-jet-engine flying wing bomber. Was their offer based on an aircraft they had already built during the war?



Bericht.

Die Ermittlungen über das Projekt "Horten-Parabel sind abgeschlossen.
Die Ergebnisse können folgendermassen zusammengefasst werden.

1.

Die Russen sind im Besitz der einschlägigen Pläne und werden von Deutschen Fachleuten unterstützt.
Der Serienbau der sogenannten Horten 13 (Modell mit 2 TL-Triebwerken) soll beim Russen nicht über das Anfangsstadium hinaus gediehen sein. Die Zahl 300 die für den Ausstoss genannt wurde, ist wesentlich zu hoch gegriffen. Die Flugzeit der Horten 13 wird von Fachleuten mit 1 Stunde angegeben. Dieses Modell ist nur zur Verteidigung geeignet.
Die grosse Horten 48 mtr. Spannweite, 6 TL-Triebwerke. 7000 km Aktions-Radius ist beim Russen nicht über das Projekt hinausgediehen, da sich nur ein geringer Teil der einschlägigen Mitarbeiter beim Russen befindet.

2

Zur Entwicklung dieser Angelegenheit wird folgender Vorschlag gemacht:
Wir sind jetzt in der Lage, innerhalb von 4 Wochen den einschlägigen Mitarbeiterstab aufzustellen, der sich mit dem obigen Projekt befasst hat. Der Chef-Konstrukteur hat bereits günstige Angebote aus der Türkei und der Sowjet-Union erhalten, erklärte sich jedoch nach Rücksprache grundsätzlich bereit für die US-Army zu arbeiten. Alle anderen in Frage kommenden Mitarbeiter (etwa 30) sind grundsätzlich zur Zusammenarbeit bereit, bitten jedoch um die Bekanntgabe der finanziellen- u. Existenz-Bedingungen, da die meisten sich nach dem Zusammenbruch eine eigene Existenz gegründet haben und naturgemäss nicht gern bereit sind, Bindungen mit Unsicherheitsfaktoren einzugehen.
Ferner ist zu klären, ob die Versuchsgruppe in Deutschland oder den Verein. Staaten arbeiten soll.
Wenn die US vorgesehen sind, so erscheint Sicherung gegen unvorhergesehene Entlassung angezeigt. (Chef-Konstrukteur macht dies zur Bedingung, da bereits mehrere Jahre in US-Flugzeug-Industrie gearbeitet, um sich gegen Eventualit. zu sichern)
Nach seinen Angaben kann nach Aufgabenstellung der konstruktive Teil in allerkürzester Zeit abgeschlossen werden.
Wenn das Projekt anlaufen soll, bitten wir um Zuweisung eines PKW u. Betriebsstoff, um die Aufstellungs-Organisation durchführen zu können.
Weiterhin wird um die Unterstützung der US-Militär-Regierung gebeten, wenn verschiedne Mitarbeiter aus der R.Zone geholt werden müssen.

Zu Beginn der Arbeit bitten wir um genaue Aufgabenstellung seitens der US-Army, z.B.
wird Holzbauweise verlangt, wieviel Triebwerke, Aktionsradius. Zuladung, Besatzungs-Stärke, Waffen-Anordnung etc.

Kalkert Abgl. Angebot, mögl. alles bauen!
Flugkapitän Hanna Reitsch
Die einschlägigen Leute hat Kalkert an der Hand

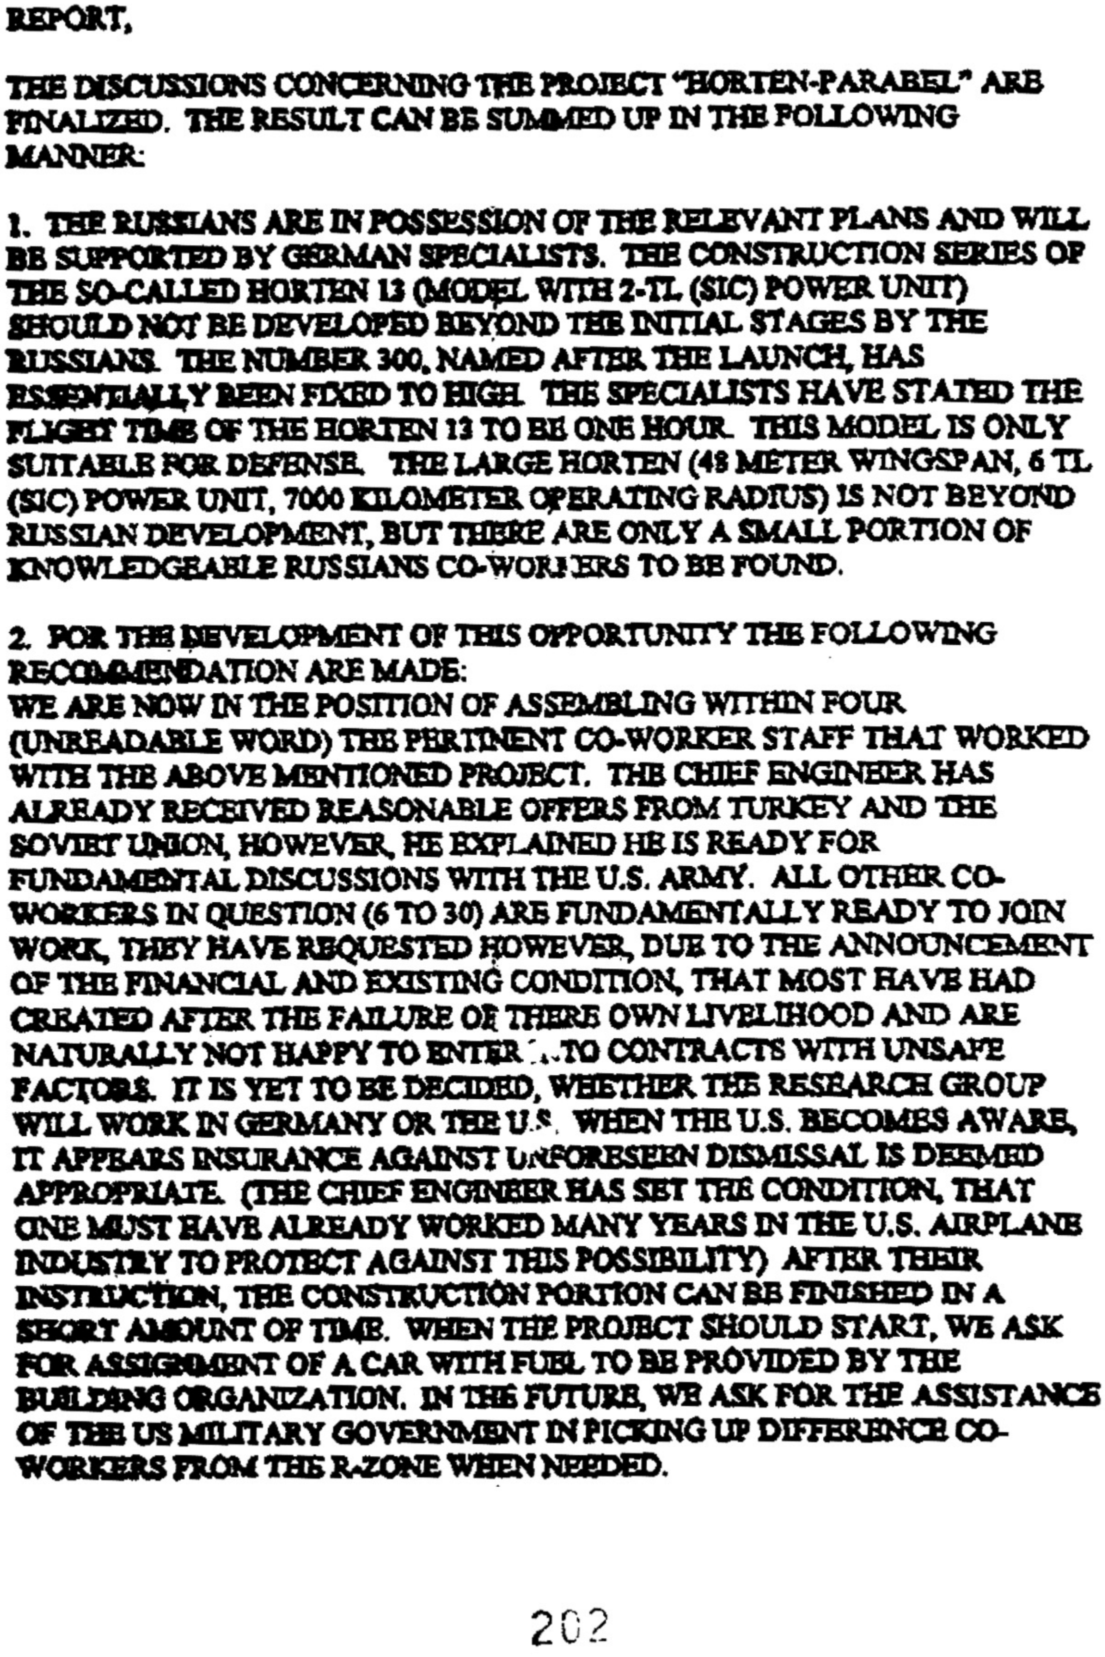
Figure E.21: After the war, a group of German aerospace engineers offered to immediately begin building for the U.S. military a 7,000-km-range (14,000-km round trip), 6-jet-engine flying wing bomber. Was their offer based on an aircraft they had already built during the war?



REPORT,

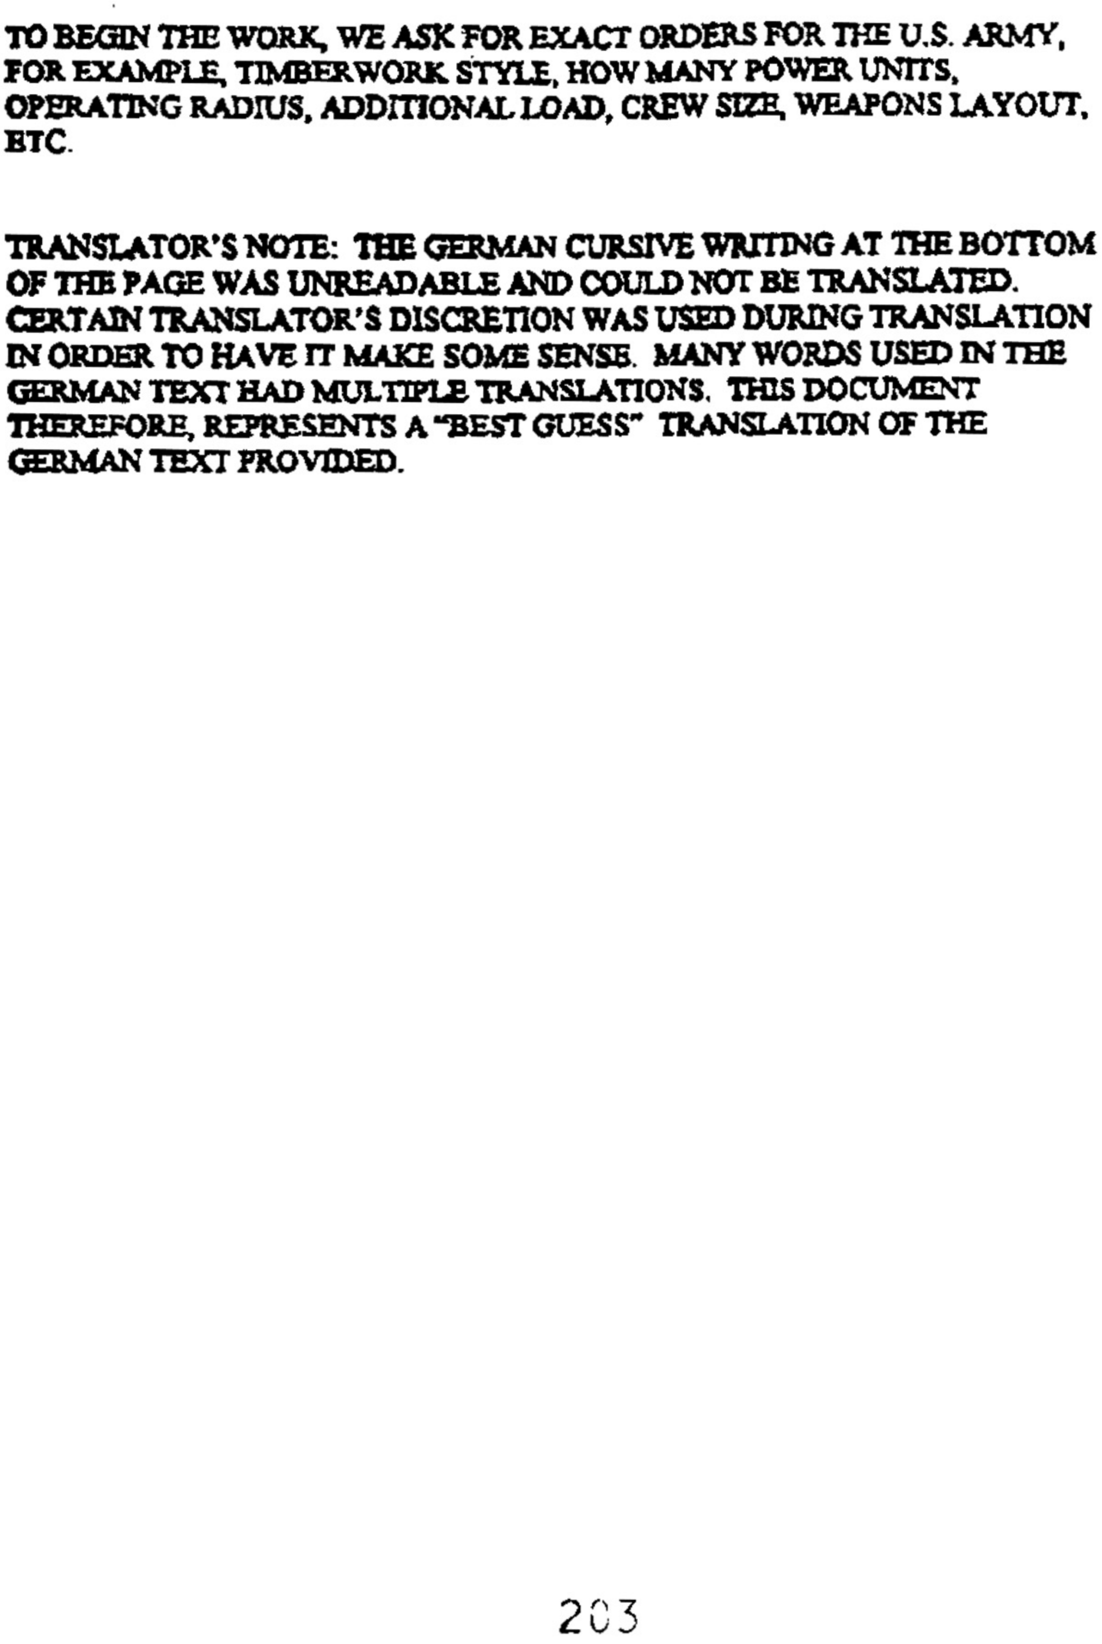
THE DISCUSSIONS CONCERNING THE PROJECT "HORTEN-PARABEL" ARE FINALIZED. THE RESULT CAN BE SUMMED UP IN THE FOLLOWING MANNER:

1. THE RUSSIANS ARE IN POSSESSION OF THE RELEVANT PLANS AND WILL BE SUPPORTED BY GERMAN SPECIALISTS. THE CONSTRUCTION SERIES OF THE SO-CALLED HORTEN 13 (MODEL WITH 2-TL (SIC) POWER UNIT) SHOULD NOT BE DEVELOPED BEYOND THE INITIAL STAGES BY THE RUSSIANS. THE NUMBER 300, NAMED AFTER THE LAUNCH, HAS ESSENTIALLY BEEN FIXED TO HIGH. THE SPECIALISTS HAVE STATED THE FLIGHT TIME OF THE HORTEN 13 TO BE ONE HOUR. THIS MODEL IS ONLY SUITABLE FOR DEFENSE. THE LARGE HORTEN (48 METER WINGSPAN, 6 TL (SIC) POWER UNIT, 7000 KILOMETER OPERATING RADIUS) IS NOT BEYOND RUSSIAN DEVELOPMENT, BUT THERE ARE ONLY A SMALL PORTION OF KNOWLEDGEABLE RUSSIANS CO-WORKERS TO BE FOUND.

2. FOR THE DEVELOPMENT OF THIS OPPORTUNITY THE FOLLOWING RECOMMENDATION ARE MADE:
WE ARE NOW IN THE POSITION OF ASSEMBLING WITHIN FOUR (UNREADABLE WORD) THE PERTINENT CO-WORKER STAFF THAT WORKED WITH THE ABOVE MENTIONED PROJECT. THE CHIEF ENGINEER HAS ALREADY RECEIVED REASONABLE OFFERS FROM TURKEY AND THE SOVIET UNION, HOWEVER, HE EXPLAINED HE IS READY FOR FUNDAMENTAL DISCUSSIONS WITH THE U.S. ARMY. ALL OTHER CO-WORKERS IN QUESTION (6 TO 30) ARE FUNDAMENTALLY READY TO JOIN WORK, THEY HAVE REQUESTED HOWEVER, DUE TO THE ANNOUNCEMENT OF THE FINANCIAL AND EXISTING CONDITION, THAT MOST HAVE HAD CREATED AFTER THE FAILURE OF THERE OWN LIVELIHOOD AND ARE NATURALLY NOT HAPPY TO ENTER INTO CONTRACTS WITH UNSAFE FACTORS. IT IS YET TO BE DECIDED, WHETHER THE RESEARCH GROUP WILL WORK IN GERMANY OR THE U.S. WHEN THE U.S. BECOMES AWARE, IT APPEARS INSURANCE AGAINST UNFORESEEN DISMISSAL IS DEEMED APPROPRIATE. (THE CHIEF ENGINEER HAS SET THE CONDITION, THAT ONE MUST HAVE ALREADY WORKED MANY YEARS IN THE U.S. AIRPLANE INDUSTRY TO PROTECT AGAINST THIS POSSIBILITY) AFTER THEIR INSTRUCTION, THE CONSTRUCTION PORTION CAN BE FINISHED IN A SHORT AMOUNT OF TIME. WHEN THE PROJECT SHOULD START, WE ASK FOR ASSIGNMENT OF A CAR WITH FUEL TO BE PROVIDED BY THE BUILDING ORGANIZATION. IN THE FUTURE, WE ASK FOR THE ASSISTANCE OF THE US MILITARY GOVERNMENT IN PICKING UP DIFFERENCE CO-WORKERS FROM THE R-ZONE WHEN NEEDED.

202

Figure E.22: After the war, a group of German aerospace engineers offered to immediately begin building for the U.S. military a 7,000-km-range (14,000-km round trip), 6-jet-engine flying wing bomber. Was their offer based on an aircraft they had already built during the war?



TO BEGIN THE WORK, WE ASK FOR EXACT ORDERS FOR THE U.S. ARMY, FOR EXAMPLE, TIMBERWORK STYLE, HOW MANY POWER UNITS, OPERATING RADIUS, ADDITIONAL LOAD, CREW SIZE, WEAPONS LAYOUT, ETC.

TRANSLATOR'S NOTE: THE GERMAN CURSIVE WRITING AT THE BOTTOM OF THE PAGE WAS UNREADABLE AND COULD NOT BE TRANSLATED. CERTAIN TRANSLATOR'S DISCRETION WAS USED DURING TRANSLATION IN ORDER TO HAVE IT MAKE SOME SENSE. MANY WORDS USED IN THE GERMAN TEXT HAD MULTIPLE TRANSLATIONS. THIS DOCUMENT THEREFORE, REPRESENTS A "BEST GUESS" TRANSLATION OF THE GERMAN TEXT PROVIDED.

203

Figure E.23: After the war, a group of German aerospace engineers offered to immediately begin building for the U.S. military a 7,000-km-range (14,000-km round trip), 6-jet-engine flying wing bomber. Was their offer based on an aircraft they had already built during the war?

Captured German Equipment, German, Box 3353, Book 15, SC 314829.]

Karl Leist, and Hans Georg Wiening. 1963. *Enzyklopädische Abhandlung über ausgeführte Strahltriebwerke.* pp. 356–360: Daimler-Benz-Triebwerk 109-007.

Die Firma Daimler-Benz begann Mitte 1939 als letzte der deutschen Firmen mit der Entwicklung von Strahltriebwerken. Dies war in ester Linie die Folge davon, daß die Kapazität des Werkes weitgehend durch die Entwicklung und Fabrikation der Daimler-Benz-Kolbenflugmotoren ausgelastet war. Auch während des Krieges, wo erklärlicherweise die in sehr viele Flugzeugbaumuster eingebauten DB-601-, DB-605- und DB-603-Motoren mit ihren verschiedenen Abarten einen außerordentlichen Einsatz des gesamten Werkes erforderten, konnte sowohl in der Konstruktion wie in der Werkstatt nur sehr allmählich die auf die Gasturbinenentwicklung angesetzte Mannschaft verstärkt werden.

Der späte Beginn der TL-Entwicklung hatte zur Folge, daß die Firma vom Reichsluftfahrtministerium, da schon genügend Firmen auf einfache Strahltriebwerke angesetzt zu sein schienen, mit einer Weiterentwicklungsaufgabe, nämlich Schaffung eines Triebwerkes mit besonders geringem Kraftstoffverbrauch für längere Einsatzzeiten, betraut wurde, welches als Zweikreistriebwerk entwickelt werden sollte. Da bei dieser komplizierten Einheit gleichzeitig ein größerer Schub als bei den anderen gefordert wurde und außer dem späteren Entwicklungsbeginn die Erfahrungen, die an einem einfachen TL-Gerät hätten gesammelt werden können, übersprungen werden mußten, ergab sich hiermit eine Aufgabe, die besonders hohe Anforderungen an die Entwicklung stellte. Außerdem führte diese zu einer großen Reihe von zusätzlichen Problemen, da die spezielle Zielsetzung des Projektes, nämlich die Erreichung höchster Wirtschaftlichkeit durch den Ballastluftkreislauf und seine speziellen Forderungen, ein besonders starkes Heranrücken an die Grenzen der ausführbaren Werte in bezug auf Druckverhältnisse, Gastemperaturen usw. forderte. Hierdurch war bei dem damaligen frühen Entwicklungsstand der Strahltriebwerke und dem gänzlichen Fehlen von Erfahrungen, auf die man sich hätte stützen können, eine schnelle und einfache Lösung sehr erschwert.

Daimler-Benz was the last of the German companies to begin developing jet engines in mid-1939. This was primarily the result of the fact that the plant's capacity was largely utilized by the development and production of Daimler-Benz piston aircraft engines. Even during the war, when the DB-601, DB-605, and DB-603 engines with their various versions, which were installed in a large number of aircraft models, required an extraordinary commitment from the entire plant, it was only possible very gradually to strengthen the team dedicated to gas turbine development, both in the design department and in the workshop.

The late start of TL [turbojet] development meant that the company was entrusted by the Reich Aviation Ministry, since enough companies already seemed to be focused on simple jet engines, with a further development task, namely the creation of an engine with particularly low fuel consumption for longer operating times, which was to be developed as a dual-flow [turbofan] engine. Since this complicated unit also required greater thrust than the others and, apart from the later start of development, the experience that could have been gained on a simple TL unit had to be skipped, this resulted in a task that placed particularly high demands on development. Moreover, it led to a large number of additional problems, since the special objective of the project, i.e. to achieve maximum efficiency through the cold air flow and its special requirements, demanded a particularly strong approach to the limits of feasible values in terms of pressure ratios, gas temperatures, etc. This meant that the development of the TL unit at that time was not possible. Given the early stage of development of jet engines at that time and the complete lack of experience on which to draw, this made it very difficult to find a quick and simple solution.

Da der geforderte Kraftstoffverbrauch außerordentlich niedrig war, mußte zu einer für damalige Verhältnisse sehr hohen Verdichtung übergegangen werden (ca. 1: 8), die, da sonst durch zu viele Kompressorstufen die Länge außerordentlich groß ausgefallen wäre und auch die kritische Drehzahl kaum hätte beherrscht werden können, zu einem gegenläufigen Verdichter führte, der in einer Lösung von der Aerodynamischen Versuchsanstalt Göttingen, in einer späteren Parallelausführung von der Firma Voith konstruiert wurde. Die Entspannungsanfangstemperatur wurde—ebenfalls mit dem Ziel bester Wirtschaftlichkeit—auf 1100^o C festgelegt. Um diese hohen Temperaturen für die Laufschaufeln erträglich zu machen, wurden diese gekühlt, und zwar vermittels einer Teilbeaufschlagung durch Luft, die nicht auf den Brennkammerdruck, sondern nur auf den Druck hinter der Turbine verdichtet war. Für diese Kühlmethode, die als einzige im praktischen Betrieb eine Temperatur von 1100^o C bereits erlaubt hatte, lagen die Verhältnisse gerade beim Zweikreistriebwerk deswegen besonders günstig, weil der Verdichter, die Turbine und die Brennkammern von dem zweiten Kreis (Ballastluft) umströmt wurden, dem die Kühlluft zwanglos entnommen werden konnte. Auch ließ sich der durch die Teilbeaufschlagung etwas größere Turbinenraddurchmesser ohne weiteres in dem Hauptspantquerschnitt unterbringen, der durch den Verdichterdurchmesser zuzüglich des zweiten Kreises sowieso nötig war. Die für die Gastemperatur von 1100^o C ausreichende Kühlwirkung der auch in der ausländischen Literatur günstig beurteilten* kühlenden Beaufschlagung mit unverdichteter Luft war vorher aus einer ganzen Reihe von Versuchen an Abgasturbinenrädern mit geeignet geformten Schaufeln festgestellt worden, bei denen Dauerläufe über 200 Stunden mit höchsten Drehzahlen bei dieser Temperatur anstandlos durchgeführt worden waren.

Since the required fuel consumption was extraordinarily low, a very high compression ratio (approximately 1:8) had to be used, which, since the length would otherwise have been extraordinarily large due to too many compressor stages and the critical speed could hardly have been controlled, led to a counter-rotating compressor, which was designed in one solution by the Aerodynamische Versuchsanstalt Göttingen and in a later parallel design by the Voith company. The initial expansion temperature was set at 1100^o C—also with the aim of achieving the best efficiency. In order to make these high temperatures bearable for the rotor blades, they were cooled by means of a partial admission of air, which was not compressed to the combustion chamber pressure, but only to the pressure behind the turbine. The conditions for this cooling method, which was the only one to permit a temperature of 1100^o C in practical operation, were particularly favorable for the dual-flow engine because the compressor, the turbine and the combustion chambers were surrounded by the duct carrying the second flow (cold air), from which the cooling air could be taken without constraint. Also, the somewhat larger turbine wheel diameter due to the partial pressurization could be easily accommodated in the main bulkhead cross-section, which was necessary anyway due to the compressor diameter plus the second flow. The cooling effect of the non-compressed air, which is also favorably assessed in foreign literature*, was sufficient for the gas temperature of 1100^o C. This had previously been established from a whole series of tests on exhaust gas turbine wheels with suitably shaped blades, in which endurance runs over 200 hours at maximum speeds had been carried out at this temperature without any problems.

---

* Vgl. z. B. JUDGE, Modern Gas Turbines.

* Cf., e.g., JUDGE, Modern Gas Turbines.

Als besonderes Kennzeichen der Konstruktion dieses Zweikreistriebwerks soll noch genannt werden, daß die Schaufeln zur Verdichtung der Ballastluft, also des zweiten Kreises, auf dem Außenläufer des gegenläufigen Verdichters angebracht waren, wodurch die Baulänge noch weiter verringert wurde.

Das DB-Triebwerk 109-007, wie die beschriebene Zweikreisentwicklung genannt wurde, sollte bei 250 m/sec Fluggeschwindigkeit in 6 km Höhe einen Schub von 600 kp erzeugen, das entsprach einer Vortriebsleistung von 2000 PS. Die Gastemperatur wurde aus den besprochenen Gründen auf 1100^o C, der Gasbeaufschlagungsgrad auf 67% festgelegt. Die Förderhöhe des Verbrennungsluftverdichters betrug 20 000 mkg/kg, die des Ballastluftverdichters 3000 m bei einer Drehzahl der Turbine von 12 600 U/min. Der Außenläufer des Verdichters der gleichzeitig die Beschaufelung des Ballastluftverdichters trug, lief mit 6200 U/min um und wurde durch ein Planetengetriebe von der Turbinenwelle aus angetrieben. Der Gegendruck der Turbine ergab sich zu 1,9 ata am Boden, so daß also weitgehend Schallgeschwindigkeit in der Enddüse herrschte. Der Luftdurchsatz betrug im ersten Kreis in Bodennähe 14,8, in 6 km Höhe 8,2 kg/sec; im zweiten Kreis 35,8 bzw. 19,9 kg/sec. Das Ballastluftvielfache betrug danach ca. 2,42.

Die Turbine war einstufig, obgleich das Expansionsdruckverhältnis bis 1 : 6 stieg, der Verdichter besaß 17 Stufen, d. h. gegenläufige Kränze. Dadurch war die Gesamtbaulänge trotz des hohen Druckverhältnisses relativ kurz.

Der feste Mittelträger unmittelbar hinter dem Verdichteraustritt hat die Rolle einer senkrechten Grundplatte, an der sich nach vorn ein die vorderen Lager tragender zylindrischer Teil als Verdichtergehäuse anschließt, und nach hinten der das Getriebe umhüllende konische Träger des Lagers der fliegend angeordneten Turbinenscheibe.

A special feature of the design of this dual-flow engine is that the blades for compressing the cold air, i.e. the second flow, were mounted on the outer rotor of the counter-rotating compressor, which further reduced the overall length.

The 109-007 DB engine, as this dual-flow project was called, was intended to produce 600 kp of thrust at 250 m/sec airspeed at 6 km altitude, equivalent to 2000 hp of propulsive power. The gas temperature was set at 1100^o C for the reasons discussed, and the gas impingement rate at 67%. The head of the combustion air compressor was 20,000 mkg/kg, that of the ballast air compressor 3000 m at a turbine speed of 12,600 rpm. The external rotor of the compressor, which also carried the blading of the cold air compressor, rotated at 6200 rpm and was driven by a planetary gear from the turbine shaft. The back pressure of the turbine was 1.9 ata at ground level, so that the speed of sound largely prevailed in the final nozzle. The air flow rate in the first flow near the ground was 14.8, at 6 km altitude 8.2 kg/sec; in the second flow 35.8 and 19.9 kg/sec, respectively. The air bypass ratio was thus approximately 2.42.

The turbine was single stage, although the expansion pressure ratio increased to 1:6; the compressor had 17 stages, i.e. counter-rotating rings. As a result, the overall length was relatively short despite the high pressure ratio.

The fixed center support immediately behind the compressor outlet had the role of a vertical base plate, to which a cylindrical part supporting the front bearings as the compressor housing was connected to the front, and to the rear the conical support of the bearing of the overhung turbine disk enclosing the gearbox.

Von den beiden Verdichterläufern ist der innere in einer Ausführung aus trommelartigen Ringen, in der anderen aus Rädern zusammengesetzt. Durch die Anbringung der zwei Stufen des Ballastluftgebläses auf dem Außenläufer des gegenläufigen Verbrennungsluftkompressors wird die Gesamtbaulänge des Kompressorteils trotz des hohen Verdichtungsverhältnisses und trotz der zwei notwendigen Verdichter sehr kurz, was der kritischen Drehzahl zugute kommt. Die erste Scheibe sowie die Schaufelringe sind sowohl beim Innen- wie beim Außenläufer aus einer besonderen Leichtmetallegierung gefertigt, die durch Nickelzusatz eine erhöhte Warmfestigkeit aufweist. Die letzten Stufen waren aus Stahl. Die Schaufeln der Erstlingsausführung waren aus dem Material der Ringe herausgeschnitten, für später war zwecks Verbilligung ein schräg einzuschiebender Schwalbenschwanzfuß für die Verdichterschaufeln vorgesehen. Die Lagerung wurde—mindestens bei der ersten Ausführung—als Gleitlagerung (teilweise mit schwimmenden Buchsen) ausgeführt mit einem Blockdrucklager zur Aufnahme des beträchtlichen Achsschubes, der durch einen Druckausgleichkolben am Außenläufer gesenkt wurde.

Die Düsen der einstufigen Turbine waren mit Rücksicht auf das sehr hohe Entspannungsverhältnis erweitert ausgeführt. Die Umfangsgeschwindigkeit des Turbinenrades betrug 375 m/sec. Das Rad ist mit Hirthverzahnung an der Welle befestigt und trägt einen radialen Schaufelkranz zur Förderung von Kühlluft zur Kühlung des Rades und insbesondere der Düsen. Ergänzend wurden Untersuchungen über eine zweistufige Ausführung der Turbine durchgeführt, die jedoch baulich ungünstigere Verhältnisse lieferte. Die Schaufelprofile warn vorn stark abgestumpft und im Verhältnis 1 : 2,7 verjüngt ausgeführt. Der Außenrand des Rades trug auf beiden Seiten eine konzentrische Umfangsrippe, die durch die radiale weiter nach innen reichende Kühlluftzuführung bespült wurde und somit dem besonders gefährdeten Radkranz die Wärme entzog.

Of the two compressor rotors, the inner one was composed of drum-like rings in one design and wheels in the other. By placing the two stages of the ballast air blower on the outer rotor of the counter-rotating combustion air compressor, the overall length of the compressor section becomes very short, despite the high compression ratio and despite the two compressors required, which benefits the critical speed. The first disk as well as the blade rings, both for the internal and external rotors, were made of a special light alloy that has increased high-temperature strength due to the addition of nickel. The last stages were made of steel. The blades of the first version were cut out of the material of the rings; for later versions, an oblique dovetail base was provided for the compressor blades in order to make them cheaper. The bearing arrangement was—at least in the first design—as a plain bearing (partly with floating bushings) with a block thrust bearing to absorb the considerable axle thrust, which was lowered by a pressure compensating piston on the outer rotor.

The nozzles of the single-stage turbine were of expanded design in consideration of the very high expansion ratio. The peripheral speed of the turbine wheel was 375 m/sec. The wheel was attached to the shaft with Hirth teeth and carried a radial vane ring for conveying cooling air to cool the wheel and, in particular, the nozzles. Supplementary investigations were carried out on a two-stage design of the turbine, which, however, provided structurally less favorable conditions. The blade profiles were heavily truncated at the front and tapered in a ratio of 1:2.7. The outer rim of the wheel had a concentric circumferential rib on both sides, which was flushed by the radial cooling air supply extending further inward and thus extracting heat from the particularly vulnerable wheel rim.

Die Zahl der Brennkammern betrug vier, wobei die Möglichkeit der Anbringung einer fünften Kammer offengelassen war, was während der Versuche bereits durchgeführt wurde. Der Luftüberschuß betrug mit Rücksicht auf die hohe Entspannungsanfangstemperatur 2,7–3. Die Düsen hatten neben ihrer hohen thermischen Beanspruchung durch die hohe Druckdifferenz der Entspannung auch hohe mechanische Beanspruchungen auszuhalten. Ihre Stege wurden daher hohl ausgeführt und von Kühlluft durchströmt.

Um den Gewinn durch den Ballastluftkreislauf vollständig zu machen, war eine möglichst weitgehende Mischung des Turbinenabgases mit der Luft des zweiten Kreises hinter der Turbine notwendig. Die Mischung geht dabei um so verlustärmer vor sich, je geringer die Strömungsgeschwindigkeit während derselben ist. Es wurden zwei Mischstrecken mit verschiedener Länge und mit verschieden aufwendigen Einbauten hergestellt, die diesem Gesichtspunkt bei verschiedenem Baugewicht und Werkstattaufwand Rechnung tragen sollten. Bei geringeren Geschwindigkeiten im Mischraum ergab sich gleichzeitig die Möglichkeit einer intensiveren Nachverbrennung ohne Erreichung der Schallgeschwindigkeit vor der Enddüse, d. h. also einer besseren Ausnutzung eines der wesentlichen Vorteile der Zweikreisers.

Der Einlaufverkleidung wurde zwecks Erzielung einer günstigen Einströmung sowohl im Stand wie bei voller Geschwindigkeit besondere Aufmerksamkeit durch Vorversuche gewidmet. Die Hilfsapparate waren mit dem Triebwerk unmittelbar verbunden. Sie bestanden aus je einer Pumpe für den Kraftstoff der Brennkammer und für die Zusatzverbrennung zuzüglich Vorpumpen, für den Schmierstoff wurden drei Druck- und drei Saugpumpen zunächst im Nabenkopf, später an einem gesonderten Apparateträger über dem Triebwerk untergebracht, an dem außerdem Einspritzregler, Drehzahlgeber, Anlasser und Zündgerät sowie Atemluftverdichter, drei Generatoren und eine Hydraulikpumpe für die Zelle usw. angeordnet waren.

The number of combustion chambers was four, leaving open the possibility of adding a fifth chamber, which was already carried out during the tests. The air ratio was 2.7–3. The nozzles had to withstand not only high thermal stress due to the high pressure difference during expansion, but also high mechanical stress. Their walls were therefore hollow and had cooling air flowing through them.

To make the gain from the cold air flow complete, it was necessary to mix the turbine exhaust gas as much as possible with the air from the second flow behind the turbine. The lower the flow velocity during mixing, the lower the losses. Two mixing sections of different lengths and with different complex internals were produced to take account of this aspect with different construction weights and workshop requirements. At lower velocities in the mixing chamber, there was at the same time the possibility of more intensive afterburning without the flow reaching the speed of sound upstream of the final nozzle, i.e., better utilization of one of the essential advantages of the two-flow mixer.

The inlet cowling was given special attention in preliminary tests for the purpose of obtaining a favorable inflow both at standstill and at full speed. The auxiliary equipment was directly connected to the engine. This consisted of one pump each for the fuel for the combustion chamber and for the auxiliary combustion plus backing pumps; for the lubricant, three pressure and three suction pumps were initially accommodated in the hub head, later on a separate apparatus support above the engine, on which were also arranged the injection governor, speed sensor, starter, and ignition unit as well as breathing air compressor, three generators, and a hydraulic pump for the airframe, etc.

Die für das Triebwerk benutzten Werkstoffe entsprachen bei den hohen Belastungen naturgemäß den besten damals verfügbaren Legierungen.

Wen auch in Anbetracht des durch den Krieg diktierten außergewöhnlich beschleunigten Entwicklungstempos viele Vorversuche, die wünschenswert gewesen wären, nicht durchgeführt werden konnten, wurde doch eine Reihe wichtiger Elemente, bezüglich derer besonders wenig Erfahrungen vorlagen, mindestens teilweise vorerprobt. Hierzu gehört insbesondere die Brennkammer und getrennt davon die Einspritzdüsen, der gegenläufige Verdichter, die Achsschublager, das Getriebe, welches bei leichtester Bauart 4000 PS übertragen mußte, die Einlaufverkleidung usw.; weiter gingen Schleuderversuche mit Überdrehzahlen, Schwingungsmessungen und umfangreiche Schaufelkühlungsversuche, Hilfsaggregatuntersuchungen usw. der Erprobung des Gesamttriebwerkes voraus. Zum Ausschleudern der Turbinenräder wurde en gesonderter Schleuderstand mit aufheizbarer Umgebungsluft und unter Absaugung auf Vakuum erstellt.

Die Gesamterprobung, die nach verschiedenen anfänglichen Schwierigkeiten mit allen Drehzahlen von der Abhebedrehzahl* 4000 U/min bis zur Auslegungsdrehzahl 12 600 U/min des Innenläufers (teilweise ohne Ballastluftverdichter) durchgeführt wurde, ergab für das erste Volltriebwerk eine Gesamtversuchszeit von 152 Stunden. Es wurde dabei auf eine Anzahl von Einzelfragen, die nicht in Vorversuchen geklärt werden konnten, miteingegangen. Teilweise wurde mit Wassereinspritzung in die Brennkammer gefahren.

The materials used for the engine naturally corresponded to the best alloys available at the time for the high loads.

Although, in view of the exceptionally accelerated pace of development dictated by the war, many preliminary tests that would have been desirable could not be carried out, a number of important elements with respect to which particularly little experience was available were at least partially pre-tested. These include in particular the combustion chamber and, separately, the injection nozzles, the counter-rotating compressor, the axle thrust bearings, the gearbox, which had to transmit 4000 hp in the lightest design, the inlet cowling, etc.; furthermore, spinning tests with overspeeds, vibration measurements, and extensive blade cooling tests, auxiliary unit tests, etc. preceded the testing of the overall engine. For spinning out the turbine wheels, a separate spinning stand was set up with heatable ambient air and under vacuum extraction.

The complete engine testing, which after various initial difficulties was carried out at all speeds from the lift-off speed* 4,000 rpm to the design speed 12,600 rpm of the internal rotor (partly without cold air compressor), resulted in a total test time of 152 hours for the first full engine. A number of individual issues that could not be resolved in preliminary tests were addressed. In some cases, the engine was run with water injection into the combustion chamber.

* Mindestdrehzahl, bei der das Triebwerk in der Lage ist, sich ohne Anlaßmotor selbst zu beschleunigen.

* Minimum speed at which the engine is capable of self-acceleration without a starter motor.

Die Brennkammerbelastung lag bei voller Drehzahl bei $94 \cdot 10^6$ kcal/Std. Die Freilaufdrehzahl rückt bei Zweikreisern, da die Ballastluft Leistung aufnimmt, ohne daß sie zur Leistungserzeugung herangezogen wird, höher als beim einfachen TL-Triebwerk. Sowohl die Einzelversuche wie insbesondere auch die Versuche am Volltriebwerk ergaben eine große Zahl von Erkenntnissen und aussichtsreichen Verbesserungsvorschlägen. Da andererseits die Aussicht gering erschien, daß dieses durch seine komplizierte Aufgabenstellung ziemlich problemreiche Triebwerk bei dem damaligen noch recht geringen Stand der allgemeinen Erfahrungen auf dem Strahltriebwerksgebiet noch innerhalb der im Rahmen des Kriegsfortgangs verfügbaren Zeit zur Betriebsreife würde entwickelt werden können, wurde die Weiterarbeit hieran von seiten des Luftfahrtministeriums zwecks Konzentration der Industriekapazität abgebrochen. Aus diesem Grunde mußten auch die im Gange befindlichen Schubmeßversuche des Gesamttriebwerks vor der Feststellung einigermaßen stichhaltiger Ergebnisse beendet werden. Auch Brennstoffverbrauchsmeßversuche, die einen Aufschluß über die Erreichung des Ziels der Zweikreisbauart mit einigermaßen zielsicher aufeinander abgestimmten Einzelmaschinen hätten geben können, konnten nicht mehr durchgeführt werden. Andererseits deuteten die zahlreichen Vorschläge für Konstruktionsvarianten und Auslegungsverbesserungen, die sich aus den Versuchen ergaben, darauf hin, daß trotz der schwierigen Aufgabenstellung bei ausreichender Zeit die Weitererprobung der mit Rücksicht auf unbekannte Havariequellen möglichst sicher und daher auch verhältnismäßig schwer konstruierten Erstausführung mindestens in der bei derartigen neuen Entwicklungen üblichen Zweit- und Drittkonstruktion eine erfolgreiche Entwicklung versprochen hätte.

The combustion chamber load at full speed was $94 \cdot 10^6$ kcal/hr. The freewheeling speed goes higher in turbofan engines than in the simple turbojet engine because the cold air absorbs power without being used to produce power. Both the individual tests and, in particular, the tests on the full engine yielded a large number of findings and promising suggestions for improvement. Since, on the other hand, there seemed little prospect of this engine, which was rather problematic because of its complicated task, being developed to operational maturity within the time available during the war, given the still rather limited state of general experience in the field of jet engines at that time, further work on it was discontinued by the Ministry of Aviation in order to concentrate industrial capacity. For this reason, the thrust measurement tests of the complete engine, which were currently in progress, had to be terminated before reasonably valid results could be obtained. Fuel consumption measurement tests, which could have provided information on the achievement of the goal of a dual-flow design with reasonably well-matched individual engines, could also no longer be carried out. On the other hand, the numerous suggestions for design variants and design improvements that resulted from the tests indicated that, despite the difficult task, given sufficient time, further testing of the first design, which was constructed to be as safe as possible with regard to unknown sources of damage and therefore also relatively heavy, would have promised successful development at least in the second and third design iterations that are customary for such new developments.

[For more information on the DB 007 and other early turbofan and turboprop engines, see pp. 1746, 1748 and Brix 2022; von Gersdorff et al. 2004; Jakobs et al. 2009; Kay 2002; Leyes and Fleming 1999.]

Ernst Heinrich Hirschel, Horst Prem, and Gero Madelung. 2004. *Aeronautical Research in Germany: From Lilienthal until Today.* Berlin: Springer.

[p. 227:] The development of the axial flow compressors for the BMW 003 and Junkers 004 engines was started already according to the requirements of the RLM. In this context a statement of *Helmut Schelp* is of significance, saying: *"Because in 1939 the development difficulties could not be foreseen, it was decided to assign as task a parallel development. Junkers was to work on a more conventional basis and BMW on a more advanced one with better technology [18]"*. For BMW this meant a compressor with seven stages, for Junkers one with eight stages for the same pressure rise. Both these compressors will be addressed later on.

Since the RLM had initiated promising development projects for turbo-jets and with a thrust of 8–9 kN (1,800-2,025 lbf), Daimler-Benz was given the task to develop an engine with higher thrust and a lower fuel consumption. The engine proposed under the direction of *Karl Leist* and tested 1943 on a test bed was one of the first bypass engines of the world [18]. For the required pressure ratio of eight, based on proposals made by *Walter Encke*, a compressor was designed consisting of two counter-rotating drums. A parallel development of the compressor was also undertaken and the compressor constructed by the company Voith in Heidenheim.

The development of the engine He S 30 under the direction of *Max Adolf Mülller* was the first engine of the company Heinkel with purely axial flow components: compressor, combustion chamber and turbine. The compressor, based on proposals by *Rudolph Friedrich* [18], reached a circumferential velocity of 313 m/s (1,027 ft/s) and a notable high efficiency of 87 per cent. The design of the compressor was based on the same considerations as for the *Wagner* engine, namely pressure transformation in the rotors and stators (degree of reaction 50 per cent). The He S 30 engine was thus superior at that time to all other designs regarding the important parameters for an aircraft like frontal area, weight and specific fuel consumption. By order of the RLM this engine development was however stopped at a time when a Me 262 with Jumo 004 engines took off on its first flight. Similar decisions of the RLM did also affect other developments.

The engines with axial flow compressors addressed here were followed by further ones with higher thrust. Apart from turbo-jet engines (TLs), developments were under way of turbo-propeller engines (PTLs) with axial flow compressors (BMW 028, Jumo 022). [...]

[p. 242:] **Combustion Chamber Development for a Bypass Engine at Daimler-Benz**

Daimler-Benz started after initial hesitation somewhat later with the jet engine development because of the large programme variety for piston aeroengines. From *Helmut Mauch* of the RLM the company obtained the difficult task to develop an engine with larger thrust and considerably lower fuel consumption. Under the leadership of *Karl Leist*, who had joined Daimler-Benz from the "Deutsche Versuchsanstalt für Luftfahrt, DVL", in September 1939 studies were commenced for the very advanced and very complex bypass engine DB 109-007 (later RLM designation) proposed by him, one of the first bypass engines of the world. After the start of the actual development work in the year 1941 the first of three test engines built was put on April 1, 1943 on a test bed in Stuttgart-Untertürkheim and reached in autumn of that year the full load rotational speed of 12,600 rpm. The combustion chamber module consisted initially of four single combustion chambers, later of five. In ground static operation a total of 50.6 kg/s (111.6 lb/s) of air flowed through the engine, of which 14.8 kg/s (32.6 lb/s) went through the gas generator with the combustion chambers. The design target for the combustion chamber outlet temperature had a very high value of 1,100 ^{o}C (1,373 K), requiring for the turbine an especially sophisticated cooling. At the end of 1943 the development was discontinued on order by the RLM [38]. [...]

[pp. 248–249:] **Turbine Cooling for the Daimler-Benz DB 109-007**

The development of turbo-jet engines at Daimler-Benz in Stuttgart-Untertürkheim began on request by the RLM in 1940/41. Preliminary work concerning the blade cooling was carried out under the leadership of *Karl Leist*, who came from the DVL in 1939, on exhaust-driven turbo-superchargers for the Daimler-Benz altitude engines. Because the bypass engine DB 109-007 possessed a turbine entry temperature of 1,100 ^{o}C (1,373 K), the single-stage axial turbine had to be cooled. A partial bleed of cooling air from the bypass flow duct was chosen, which was supplied via slots from the secondary air duct. Preliminary tests for these methods were performed at Daimler-Benz on exhaust gas turbine wheels also already at high gas temperatures. For supplying the cooling air a radial blade ring on the turbine rotor was responsible, a kind of radial fan. [...]

[p. 407:] A further aspect of the development of the jet engine was the introduction of the so-called bypass engine as powerplant for civil transport aircraft at the beginning of the sixties and the subsequent increase of the bypass ratio. This led to various research and development tasks of the past two decades and will be dealt with in the following in more detail. Bypass engines were, however, already the subject of investigations at the beginning of the jet engine development and were realized at the company Heinkel as engine He S 10 and particularly in 1943 tested in the successful test-bed runs of the Daimler-Benz bypass engine DB 109-007 with a thrust of 11.3 kN (2,543 lbf) and a bypass ratio of 2.42 [1]. The He S 10 was perhaps the most practical bypass engine that has been designed (1940) in the early days of the jet engine [2].

[How far did work on turbofan engines such as the DB 007 actually progress during the war? How much did German wartime work on turbofan engines influence postwar work on turbofan engines such as the General Electric CJ805-23 (also by German-speaking creators)?]

National Air and Space Museum. General Electric CJ805-23 Turbofan Engine, Cutaway. https://airandspace.si.edu/collection-objects/general-electric-cj805-23-turbofan-engine-cutaway/nasm_A19760792000

In 1956, based on the commercialized CJ805-3 version of the military J79 turbojet then powering the Convair 880, GE began development of an aft fan engine, the J79-X220, later designated CJ-805-23. This uncomplicated and low cost development increased take-off thrust by 40 percent, lowered specific fuel consumption by 15 percent, and reduced takeoff and landing noise. The engine became the first U.S. turbofan and, on the Convair 990 in the 1960s, the first in the world to enter airline service.

George E. Smith and David A. Mindell. 2000. The Emergence of the Turbofan Engine. In: Peter Galison and Alex Roland, eds. 2000. *Atmospheric Flight in the Twentieth Century.* Alphen aan den Rijn: Kluwer. pp. 107–155.
https://vdoc.pub/documents/atmospheric-flight-in-the-twentieth-century-7o4lo0covue0

[p. 127:] Peter Kappus, the principal advocate of the turbofan engine within GE, then began pushing the concept of an aft fan. The idea was to install an independently rotating fan rotor behind the gas generator. The exhaust from the gas generator would drive turbine blades mounted on this rotor, and fan blades would extend from the tips of the turbine blades. This idea dates at least as far back as a Whittle patent [50] and the Metro-Vick counter-rotating fan discussed above. One of the leading academic experts on turbomachinery, G. F. Wislicenus of Penn State University, had promoted its advantages in a talk entitled “Principles and Applications of Bypass Engines” presented at the Society of Automotive Engineers Golden Anniversary Aeronautical Meeting in April 1955. The most obvious advantage of an aft fan from GE’s point of view was that a new core engine would not have to be developed. GE could use the J-79, or what amounted to almost the same thing, its commercial counterpart, the CJ805. [...]

[p. 142] Why then was P&W not the first to come up with a superior turbofan engine? Perhaps P&W had no influential in-house proponent of turbofan engines, comparable to Peter Kappus at GE. But this can at most be part of the answer, for the potential of bypass engines to realize high propulsion efficiency in the high subsonic flight speed range had been known for years, and Wislicenus had called attention to it prominently once again in 1955. So, the answer must also include aspects of P&W's engineering style and orientation. [...]

[pp. 144–145] As a first step toward unraveling this complexity, we can identify the several local factors that lay behind General Electric's developing their first turbofan, the CJ805-23, when they did: (1) persistent advocates of fan engines within GE, especially Peter Kappus; (2) an established gas generator with sufficient specific-power to drive the fan; (3) the aft fan concept, which allowed the turbofan engine to be developed at remarkably little cost; (4) the realization, which emerged in the last years of the NACA supersonic compressor research program, that comparatively high Mach number transonic stages could be designed without first having to learn how to control shocks; (5) the shift of key figures in this research program from NACA to GE, especially Lin Wright; (6) the advent of the computer, allowing the introduction of streamline-curvature methods for analyzing radial equilibrium effects in compressors; (7) the idea of adapting streamline-curvature methods to provide a through-blade analysis that could define a blade contour precisely tailored for the significant radial redistribution of the flow that occurs within a high pressure-ratio transonic blade row. Three other factors may have been important in GE's decision to commit money to developing the CJ805-23: (1) Rolls-Royce's Conway engine, perceived perhaps by some as heralding the advent of bypass engines; (2) Pratt & Whitney's overwhelmingly dominant position in high-subsonic flight, achieved initially through their J-57 on the B-52 and then in the process of being repeated by the commercial version of the J-57, the JT3C, on the Boeing 707 and Douglas DC-8; and (3) Wislicenus's talk at the SAE Golden Anniversary Aeronautical Meeting, promoting the concept of an aft fan engine.

R. P. Linstead and T. J. Betts. 15 September 1945. *The Intelligence Exploitation of Germany. Report of Combined Intelligence Objectives Subcommittee.* G-2 Division, SHAEF. Ch. 4, pp. 37, 62–67. [AFHRA A5186 electronic version pp. 904–1026]

Certain items have been omitted because of security considerations. [...]

German progress in aerodynamics, particularly aircraft capable of super-sonic speeds, was the subject of intensive investigation by British and U.S. specialists. A wind tunnel, which is considered as probably the most advanced in the world was discovered near Kochel in the Bavarian Alps. This tunnel, with a test section 40 inches square, was capable of developing wind speeds of 3,360 miles per hour by utilizing only 880 kilowatts of electrical power. The maximum wind speed which could be obtained by this tunnel approached a Mach No. of 7.6 or 5,800 miles per hour. The power plant of this wind tunnel had a rated capacity of 57,000 horsepower.

The exceptional testing facilities provided by the German super-sonic wind tunnels made possible aerodynamic research by German experts which, at this writing, appears to be more advanced than any similar development in the United Kingdom or United States.

Perhaps the most important aerodynamic intelligence obtained related to the “swept-back” wing. Many authorities believe the development of the swept-back wing had never received the attention it deserved in British and United States aero-research establishments. Investigation of new German models and prototypes incorporating these wing features has disclosed apparent advantages. The sharply swept-back wing results in a substantial increase in the critical Mach number in speeds approaching supersonic velocities, therefore the development of shock waves and excess drag at extremely high speeds is minimized.

A second enemy aerodynamics development of perhaps equal significance is the trapezoidal wing. When tested at supersonic speeds, this type of wing has resulted in improved ease of control due to the slight shift of “center of pressure” in relation to center of gravity occurring when this wing design is used.

It was discovered that German designers had placed considerable emphasis on air duct designs for high-speed aircraft. An important design feature for which full data has been obtained is that of a center rod placed in the air duct. This device minimized pressure build-up and eliminated shock waves.

A research airplane known as the DFS-346 had been designed for the purpose of testing all flying qualities at extremely high speeds in the free air. This prototype was designed to test stability, controllability, maneuverability, the values and distributions of the forces of directional controls on the wing and on the tailplanes, and other essential conditions of flight. This plane was to be capable of a 1,250 miles per hour speed and a 66,000 foot ceiling. Investigation of German aerodynamic research records and interrogation of leading design personnel has disclosed that tests of aerodynamic speeds in wind tunnels did not always agree with actual tests of prototypes in the free air. The DFS-346 was designed for further research into the unknown conditions of supersonic speeds, notably the pronounced shifts of the center of pressure.

Of probably equal importance was German research activity in jet and rocket propulsion. Enemy developments in these latter fields were in general more advanced than our own. Interesting discoveries were encountered in the design of combustion chambers for greatly increased thermal efficiency and minimum pressure loss. Enemy technicians had devoted energy and skill to the design of jet turbine blades capable of withstanding extreme stresses and high temperatures. A particularly interesting development is that of the ceramic metal turbine blade which was molded with a composition of 100% metal at the rotor end of the blade with a gradual decrease in metal content until the composition became 100% ceramic at the blade tip. This type of construction had the advantage of providing the strength of metal at the base of the blade, where the greater stresses occur, and the heat resistant qualities of ceramics at the outside tip where temperatures are most extreme. Other innovations of blade design provided ingenious air vents or water-circulation-blade cooling. Hollow steel blades were discovered which possessed considerable advantage over blade types previously known. Another discovery was a construction and assembly technique in the production of turbine blades and rotors which used a novel method of welding pressed-steel materials. This method eliminates the cost of extensive machining and slashes man-hours required from approximately six hundred to ten.

German design of automatic controls for jet motors are believed to hold much promise when applied to similar work in the United States and the United Kingdom. These controls automatically regulate fuel ratios for optimum performance under given conditions. It was discovered that German jet motors normally incorporated bullet shaped devices which could be moved back and forth in the jet outlet varying the area of the nozzle, thereby keeping the engine working at maximum efficiency and economy.

A vast amount of enemy development on jet fuels was discovered. Test and development data covering 1,100 different fuel combinations have been obtained as a result of CIOS investigations. Of special importance are the German “multi-fuels” which provide specific chemical-dynamic characteristics for given combustion chamber designs. Fuel and water injection for turbojets permitted development of sudden bursts of speed when required. Test results indicate that a 14% increase in jet thrust can be sustained for five minutes.

[...] A new enemy method of attaching fins to air cooled engines is expected to provide a substantial saving in labor and expense.

United States and British experts were impressed with the extremely compact and simple arrangement of engine accessories in integral power units. The methods used have resulted in improved engine serviceability.

Investigation of German accomplishments in the aircraft instrument field revealed a new process which permits winding of potentiometers with very fine wire (approximately 1000th of an inch in diameter). This process permits extremely refined control by automatic pilot operation.

Roy Fedden. German Plans to Revolutionise Air Warfare. *Daily Telegraph & Morning Post* 1 October 1945, p. 4.

[...] In the course of two recent visits to Germany, as leader of a technical mission for the Minister of Aircraft Production, I have seen enough of their designs and production plans to realise that if they had managed to prolong the war some months longer, we might have been confronted with a set of entirely new and deadly developments in air warfare.

Atomic Explosives

There is some reason to believe that Hitler had been promised atomic explosives by October of this year, and if Germany had been first to use them the idea of changing the whole course of the war from a small base in the South German Mountains is by no means so far-fetched.

A new range of very high-speed fighters and jet bombers was already flying, or within a few weeks of flying, when the war ended. Immense developments were under way with robot rocket weapons, some of which had already started in production. They were simple and cheap to make, and with atomic explosives even a few such devices could have placed air warfare on a new nightmare plane of impersonal long-distance annihilation such as we have not so far contemplated. [...]

Superb Test Equipment

To an engineer who has seen the wonderful efforts made by the British aircraft industry with the restricted facilities at its disposal during the recent war, and the very small number of available scientists and trained investigators, it is staggering to see the lavish research plant and vast accumulation of most modern test equipment available in Germany.

Their scientific laboratories, supersonic wind tunnels, and high-altitude engine test beds are in some ways ahead of anything existing anywhere else in the world to-day. We witnessed tests of a jet propulsion engine on a high-altitude test plant which was capable of producing wind speeds above 560 m.p.h. and altitude conditions of over 36,000 ft. The plant was superbly equipped, and remotely controlled from a sound-proof room.

The power required to deliver refrigerated air in huge quantities at high speeds, and to run all the auxiliary services, was over 10,000 kw.

The cost of this engine test plant alone was 6,000,000 marks. Extensions in hand would have raised it to 9,000,000 marks, and four other similar establishments were in course of construction elsewhere. [...]

As soon as we depart from the orthodox aircraft with piston engine and airscrew and enter the field of thermal jet propulsion, a multiplicity of possible solutions presents itself, of which the turbine jet propulsion unit, as we now know it, is only one. The Germans tackled every line likely and unlikely, and they had already obtained some wonderful research results from their bold approach and lavish expenditure, but they came just too late to avert defeat. [...]

This thoroughness is typical of the German approach to any new problem, and it was only possible to pursue this course at such a critical period of their history by reason of the large number of highly trained and experienced technicians available.

The first fruit of their labours was, of course, the flying bomb V1. [...I]t was a historic weapon which marks the beginning of the new German conception of air warfare. [...]

When the V2 rockets, travelling faster than sound, began to blast the London suburbs, the pattern of the future became clearer. [...] Right up to the time when our armies overran the launching sites, no defence had been possible against them other than bomber attacks on the factories and assembly points.

Big V2 Output

The ordeal which might have faced the British people if the land forces had not liberated France, Belgium and Holland in time may be gauged from the fact that, at one underground factory I visited, slave workers had been producing V2 rockets at the rate of 1,000 a month, despite our bombing.

It is reported that the V2 attacks were to be supplemented by long-range incendiary rockets, fired from bomb-proof emplacements, and underground rocket guns with barrels of unprecedented length were being constructed on the invasion coast for the bombardment of London.

Another new weapon which was already in production, and had been used experimentally against our bombers over Germany, was an inter-aircraft rocket, fired from an aircraft shadowing the bomber formations at a safe distance, and controlled by a wire paid out from a spool. It had a speed of 620 m.p.h. and carried a warhead of 110 lb. It could be made in ten hours and cost only 250 marks.

Guiding V3 to Target

Even more interesting was the Schmetterling or Butterly, to be known as V3. This was a rocket missile to be fired from the ground, to defend very important targets against our bombers. It was beautifully shaped, with sharply swept back wings of about 7 ft. span, and had a speed of from 560 to 620 m.p.h.

It was controlled initially by radio, but was being developed with an acoustic "ear" and photo-electric "eye," which would enable it to follow and strike down the bombers automatically, once ground control had guided it into the vicinity of the attacking formations.

The rocket motor weighed a mere 350 lb, took less than 60 hours to make, and cost about 500 marks, but for a short period it gave a thrust greater than the most powerful aero engine or jet propulsion unit in production to-day, and it was said to be effective up to 30,000 feet. It was reported to be in production at the rate of 1,000 a month at one factory alone.

At the opposite extreme, some of the German designers had found time to scheme out proposals for passenger-carrying rockets which would cross the Atlantic in under an hour, but this was the only case of any interest in peaceful aviation which I heard of during my two visits.

Huge Power at Low Cost

[...] The new German rocket motors were in effect compact and very neat editions of the big V2 rocket unit, using a mixture of nitric acid and a hydrocarbon as fuel. Their fuel consumption is enormous, and their duration correspondingly short, but they give tremendous power at negligible cost, and every possible application for them was being explored. [...]

The Me. 262, first jet-propelled fighter to go into action in the war, was a practical machine capable of well over 500 m.p.h., but with two small rocket thrust augmenters, each giving about 2,700 lb thrust in addition to the 1,700 lb thrust given by each of its main engines, it was capable of phenomenal performances for short periods and was credited with climbing to 39,000 feet in three minutes. The thrust augmenters are permanent attachments which can be used as required by the pilot as long as the fuel lasts.

All possible drive was going into the development and production of both rocket and jet propulsion units. The jet propulsion turbine units, the Jumo 004 and the B.M.W. 003, were already in series production when the war ended, and experimental work was well advanced on a new range giving much higher powers.

The most modern production plant had been assembled in new bomb-proof underground factories, and by the spring of this year jet unit production was up to between 2,000 and 3,000 a month. By the middle of 1946 production was scheduled to reach a rate of 1000,000 jet units a year.

The German jets are in several ways not as efficient as our own, but they have certain features, such as air-cooled turbine blades, and small overall diameter, which merit careful study, and they are designed for rapid production at minimum cost.

German aircraft designers were working against time to produce an entirely new range of very high-speed fighters and bombers, using turbine and rocket jets.

Rocket-Driven Fighter

The little Me. 163, the only rocket-propelled fighter of the war, although actually a failure, was a remarkable experiment and indicates the shape planned for German high-speed aircraft if the war had continued.

It has a rocket motor weighing perhaps one-tenth as much as the engine and airscrew of a conventional fighter, and costing a fraction of the price. It has no tail and its wings are sharply swept back, so that it looks rather like a boy's paper dart. Its duration is short, but it is extremely fast and represents a conception capable of great development.

Two new Messerschmitt turbine jet fighters designed to do over 600 m.p.h. were being built on similar lines, with sharply swept back wings and very small fuselages carrying equally swept back tail surfaces. I saw one of these, which was within a few weeks of flying when the war ended.

The German technicians admitted that recent research work evolved in their superb wind tunnels at Goettingen and Volkenrode, near Brunswick, had completely revolutionised their ideas on the shape of high-speed aircraft, and they were putting the new conceptions into practice with all possible speed.

A new Horten tailless fighter with two jet engines was said to be nearly ready for flight testing, and Junkers were working on a tailless bomber with four jet engines.

Meanwhile production work was being rushed ahead on new bombers of more conventional shape.

Flight at Speed of Sound

Everywhere one found the utmost enthusiasm for jet propulsion for military aircraft. Aircraft designers said it simplified their airframe design problems, and in one case it was claimed that a new jet fighter had flown within seven months of the inception of the project.

Their many high-speed wind tunnels and elaborate laboratory equipment had already yielded a fund of data with which the Germans were confidently tackling the problems of flight at sonic speeds. [...]

U.S. Air Forces in Europe. 1946. [AFHRA C5098 electronic version pp. 586–602; http://www.indianamilitary.org/FreemanAAF/OperationLusty/OperationLusty-s.pdf]

At a medieval inn near Thumersbach near Berchtesgaden, early in May 1945, the German General Air Staff patiently awaited the outcome of surrender negotiations taking place in the North. They had arrived by car and plane during the past weeks, when the fall of Berlin was imminent, and had kept in contact by radio with Admiral Doenitz at Flensburg. Through the interception of one of these messages, their location, which had previously been unknown, was discovered. Within twenty-four hours Lt Col. O'Brien and his small party, representing the Exploitation Division of the Directorate of Intelligence, USAFE, had arrived, located the party and conducted the first of a series of discussions with General Koller, who was then in command. All documents and records that had been brought by the High Command were immediately turned over, and the first unearthing of buried records and documents, in and around Berchtesgaden, as well as the initial interrogation of the staff officers present, took place.

A casual remark made by a technical engineer, who stated that he had recently been offered a position in Japan, led to his being thoroughly interrogated for significant technical information. As an aside, and what he probably considered a relatively unimportant incident, he stated that less than a month ago, about the middle of April, ten submarines heavily loaded with the latest German equipment relative to aerial warfare, were dispatched from Kiel to Japan. When Lt Col. O'Brien was thus informed he immediately advised the Directorate of Intelligence, USAFE, who in turn notified the Japanese Intelligence Section of SHAFE. A cable was then dispatched to all commands.

In every theater of war, all vessels in ports and at sea were notified, and one of the biggest searches ever undertaken during the war for submarines was initiated. What route they had taken, whether they had gone alone or together, no one knew. But so extensive was the search and so carefully was it executed by warships of all Allied nations, that by the end of June, six of these ten submarines had been captured intact, some a relatively short distance away from their bases, others perilously close to Japan.

In a mountain side near the camp of the German Staff officers, an air raid shelter had been blocked up and then carefully covered and concealed with dirt. Its presence was eventually revealed by the officer who had directed this concealment, but only after he had noticed that a hole, large enough for a man to crawl through, appeared in one or the sides. Thinking that the cache had been discovered, he explained to the USAFE party the location of the shelter, informed them that he had been in charge of the burying of some extremely important records of the High Command, and would be glad to supervise their excavation. When the contents were eventually removed, one important document after another was laid out and carefully examined. One file contained correspondence from 1 Gruppe/6 Abteilung, German Air Ministry Intelligence, dated January 1943 to March 1945, concerning the supply to Japan of all types of equipment for aerial warfare, including models of Me 262 and Me 163, quantities of V1 equipment, high explosives, incendiary bombs, bomb sights, radar apparatus of all description, including models of the Wurzburg and Freya radio and signals installations, telephone, teleprinters, and so forth, and all types of aircraft parts. Another contained the precise location of every plant in Japan presently engaged in the manufacture of the latest aerial plane designs, every research institution connected with the Japanese Air Force, and, many vital targets hitherto unknown and unsuspected by Army Air Forces Intelligence officers. These volumes were flown at once to Washington, D.C., and shortly thereafter bombers of the 20th Air Force were doing precision bombing of the secret targets whose existence had been disclosed in the documents captured at Berchtesgaden.

A report reached Lt Col O'Brien's party that a "strange aircraft" had been seen in a mountainous retreat near Salzburg. Investigation quickly determined that this "strange aircraft" was a jet-propelled helicopter, the only one of its kind in the world. The inventor and his entire staff, who had laboriously worked ten years to perfect it, were present, guarding his invention as one would a precious jewel. The helicopter was examined, and a preliminary superficial interrogation of the staff was sufficient to reveal its tremendous importance. It was carefully loaded in a large truck and taken to Munich. From there it was sent across Europe to France, placed on a boat and shipped to Wright Field, together with the confiscated notes, drawings, and meticulous records of experiments conducted by the scientist and his assistants. After lengthy and detailed interrogations of these persons by technical experts assigned to USAFE, the men were sent to P/W cages. After ten years of labor they were left with only their memories of a remarkable technical achievement. The only jet-propelled helicopter in the world had been found and disposed of in such a way that it would prove advantageous to American scientists and the government.

The presence of the USAFE party at Berchtesgaden before surrender negotiations had been concluded, the interrogation of a technical engineer and the subsequent seizure of six submarines, the unearthing of a detailed list of important and unknown Japanese laboratories, plants, and factories, the finding of a jet-propelled helicopter, and invaluable documents and records of the German General Staff, was neither accidental nor the result of fortuitous circumstances, but rather the outcome of a well-defined and executed policy known as "OPERATION LUSTY", which was the code designation for a project with a priority equal to those of military operations that had been put into immediate effect in April 1945. This project was a combined effort of the Exploitation Division of the Directorate of Intelligence, USAF, and the Disarmament Division of the IX Air Force Service Command. Its mission was the complete and minute exploitation of air intelligence and technical air objectives in liberated and hostile countries, which at that time were divided up into zones either already occupied or to be presently occupied by the 6th, 12th, and 21st Army Groups.

There was a substantial foundation for the belief that the Germans had made many, if not all, of their recent scientific developments available to the Japanese. The knowledge of these developments, consequently, was vitally needed to devise effective technical and tactical countermeasures, and to insure the technical superiority of our own equipment in the war in the Pacific. In February 1945, officers at Wright Field had prepared a list of enemy equipment, which subsequently became known as the CATEGORY "A" LIST, that they desired for technical intelligence and research purposes necessary for the execution of the above needs. This list, which was later supplemented and revised in the light of discoveries made, became the guide and working manual for teams later sent into the field by the Exploitation Division to discover, guard, and dispatch material for the expressed intelligence purposes. Headquarters, Army Air Forces, also prepared a large detailed pamphlet entitled "Air Staff Post Hostilities Requirements", which was an outline of proposed studies to be written on the German Air Force from evidence subsequently to be unearthed, discovered, and captured by members of the Exploitation Division. Thus, the exploitation logically fell into two categories: Technical and Non-Technical.

The Technical Intelligence Objectives were classified in two categories: (a) equipment or documents of immediate interest and value to technical research centers in the United States for evaluation and immediate application in the war against Japan, and (b) equipment or documents of interest to technical research centers in the United States for extended period of study and development. The Non-Technical Intelligence Objectives included the obtaining of equipment and information that would fulfill, in part, the requirements as outlined in the "Air Staff Post Hostilities Requirements". In general, these included the finding of such material as would enable officers to prepare scholarly reports on every aspect of the German Air Force: Organization & Personnel, Records & Reports Systems, Tactical Employment, Training, Installations, Air Defense, Maintenance & Supply, Aviation Medicine, Intelligence Organization and Procedures, Flying Safety, and Weather.

To handle, expeditiously, captured German aeronautical and industrial equipment the Directorate of Intelligence set up three collecting points in the forward area on 1 May 1945: Merseberg, Nuremberg, and Stuttgart airfields. Additional sub-collecting points were also established to feed the main centers. Later, when Merseberg fell under British jurisdiction, after Germany had been divided into zones, it was closed, and Munich, which eventually became the chief collecting center, was opened. Each of the points was maintained by technical personnel thoroughly acquainted with the type of intelligence material desired and the necessary equipment to explore all technical intelligence targets in the areas. An ATI (Air Technical Intelligence) team control section was established at each collecting point to supervise the several hundred mobile ATI teams, which usually consisted of two to four technicians and a driver fluent in German, exploiting both technical and non-technical targets in the forward areas. Captured technical equipment was taken to one of the collecting points where it was flown either directly to Washington or Wright Field, depending upon its importance, or across Europe to shipping ports in France. Technical documents and reports were likewise sent to collecting points and from there to the Air Documents Research Center in London, which was specifically set up to receive the thousands of sheaves of documents being sent from the various collecting points in Europe.

These ATI teams, upon whom fell the often laborious task of ferreting valuable information from German civilian scientists and enemy personnel who were frequently reluctant to talk or to tell the truth, were composed of perhaps the most heterogeneous group of men ever collected in the army to execute a valuable and important job. There were Army officers and enlisted men fluent in German, Austrian, Russian and the Slavonic languages, skilled lawyers, scientists, research scholars, historians, and technical representatives from such corporations as Bell Aircraft, Jack & Huntz, Western Electric, General Electric, Standard Oil, Sperry, Packard, Boeing, Bendix, Detroit Broach, Remington Rand, and Victor Adding Machine. In six weeks of operation they had exploited more than five hundred important targets and interrogated hundreds of eminent German scientists, research professors, technicians, and workers.

The difficulties encountered by ATI teams sent into the field to investigate a target were numerous and complex, offering, in some cases, no reward, or little at all, after days of laborious travelling, often in foul weather, over deteriorated roads, and after gruelling hours of interrogation in unfavorable circumstances. The information given a team about a target, moreover, was often too vague for quick and successful exploitation, and the quest frequently turned into a sleuthing job with information so scanty that a well-trained detective would have despaired. Excerpts from several reports from such teams present a graphic picture of the discouragement and difficulties so often encountered:

"Of the 11 cases of ZWB (Central Publishing Agency for German Scientific reports) in a chapel", writes an Air Force officer in charge of a team sent to investigate German Research Installations at Schloss Pullach/Aibling in Bavaria, "5 were empty......Herr Becker explained that Herr Strohmeier, the Secretary of the Lilienthal Gesellschaft, had disposed of them....... when the latter showed up, we were able to interrogate him in Becker's presence. The result was a considerable flop on the part of both gentlemen, since Strohmeier told an entirely different story. After hours of heated interrogation, Strohmeier gave way and led us to a spot in the garden where we ultimately recovered about a ton of buried documents. There was also a smaller hoard which he yielded up."

In search of additional documents, the President of the Lilienthal Gesellschaft was interrogated at Schloss Pullach, a few kilometers away.

"He had no documents and told substantially the same story as Strohmeier that the documents had been conveyed by rail from the Schloss to a "Tischlerei" in the Mittel Zelle Church. When the French Army approached, Baeumker and Strohmeier first tried to throw the cases of documents in the lake in the hope that they would sink, but that failed. Then they got a number of people together and burned the lot on the beach. This took them two days, and they were barely able to get back to Schlagenhofen and Bibling respectively before occupation."

From Pullach the team went to Ainring in an attempt to locate the Forschungs-Fuehrung. After two days of investigation they found........

"that the greater part of the important documents was gone, and that the place had, in general, been cleared of interesting documents by occupying troops as well as looters, although a substantial quantity of peculiar airplanes and mechanisms remained on the field ....we found our main problem the necessity of locating the "Forschungs-Fuehrung, over which Georgii had presided.

After much travelling in quest of the members of the "Forschungs-Fuehrung", the team located some of them on a cart road near a swamp.

"These people were briefly interrogated and proved to have very few documents or anything else left all parties told the same story of the fate of the major portion or their records, namely, that they were destroyed by fire and bombs in a raid. The Germans in the area were thoroughly spoiled and had lost most of their rear of us."

In locating desired target intelligence, teams all too frequently found German personnel reluctant to reveal the location of missing material, which, they claimed, was usually either already burned, destroyed, or forever lost. They manifested a reluctance to speak, deliberately lied to mislead, the intelligence workers, or feigned complete ignorance of the subject under question. One team captain in a report of a trip that took his party to survey the Luftfahrtforschungsanstalt found that....

"there was always some kind of a Restkommande" Jerry waiting to give a conducted tour of whatever we were investigating; generally someone surprisingly well informed The appearance of these various individuals so ready to collaborate with us is part of a pre-arranged plot controlled by unknown parties with the following objectives:

(1) To keep a close check on our activities and to learn our purpose from our questions.

(2) To establish themselves, especially in the factories and other concerns, as a kind of quisling government, operating under our nominal and their actual control.

(3) To guide us away from really important information.

(4) To make themselves indispensable and so keep alive the framework of the IVth Reich.

(5) To sow dissension among the various allied governments. (This might easily take the form of claiming that certain vital records have fallen into the hands of another government.)”

But, on the other hand, there were many scientists willing and anxious to collaborate and work for the United States. Various team captains stated over and again in their reports that the better grade scientists were not ill-disposed toward the Allies.

“They seem to regard”, one wrote, “the initial stages of the occupation as a temporary and regrettable interruption of their work, and are interested only in continuing their activities under any auspices. They do not understand why the Allies do not put them to work at once for our purposes. At Gottingen, some asked if they could not get grants of money from American institutions, such as the Carnegie Institute, for resuming their work..... There is no evidence”. he concludes, ’ ”that the war has changed moral values; but rather evidence to the effect that the loss of the war is regarded merely as an unpleasant and passing material incident. The hazard of continuing any scientific war work in Germany, even under the closest supervision, is all too obvious.

Team members often found, after initiating the exploitation of targets, that there were clues at each target which lead to others unknown: these usually were investigated at once. Quite frequently it was discovered that the Germans had almost always abstracted the documents they considered most valuable, generally hiding rather than burning them. Under pressure, however, their presence was revealed, quite frequently in lakes, swimming pools, mines, barns, buried in closed over shelters, tucked away in attic corners or in cellars of houses scattered over the country, in jails, insane asylums, or even grocery stores.

This detailed search throughout Germany, specially made to capture technical equipment to further our war against Japan and to provide research and materials for extended periods of study and development, was responsible far the successful and quick completion of scientific developments upon which the Government had already been directly or indirectly engaged. As ATI ordnance flak, armament, electronics, and other exploitation teams, fanned out in their extensive and exhaustive searches through arsenals, laboratories, factories, supply dumps, and airdromes in Germany, one important high priority target or opportunity and one combined intelligence objective target after another were investigated and exploited to the maximum.

The targets briefly discussed below may serve as illustrative examples of the tremendous scope and nature of exploitation that took place under the name of “OPERATION LUSTY”. One may reasonably be assured, moreover, that in this exhaustive intelligence search nothing of importance escaped detection, examination, and subsequent application. Practically everything of importance that was obtained and accomplished was done so during the first six operative weeks of the project, when it was so imperative that every technical effort be made to bring to a quick and successful conclusion the War in the Pacific.

(1) The Hermann Goering Aeronautical Research Establishment, located near Brunswick, yielded the greatest return in the field of research. Members of the Exploitation Division arrived on the 22nd April to organize and conduct the scientific exploitation of this establishment. Dr. von Kármán, General Arnold’s personal aeronautical advisor, and his Group, remained at this place, on several occasions for periods varying from several days to a week. According to Dr. von Kármán, seventy-five to ninety per cent of the technical aeronautical information in Germany was available at this establishment, and that information on research and development which had not previously been investigated in the United States would require approximately two years to accomplish with the

facilities available there. Information obtained on jet engine developments available at the Goering establishment, it was stated, would expedite the United States development by approximately six to nine months. In less than two months, one hundred and nineteen reports were written on the facilities, the research conducted there, and on the interrogation of many of the German scientists previously employed in the various institutes. The permanent members of the organizing party recovered from localities, as far as 50 kilometers from Brunswick, large quantities of buried and hidden documents and equipment which had been removed by the Germans to prevent their falling into the hands of Allied forces.

(2) During the exploitation of the aviation fuel objective—of which the I. G. Farben Ind. at Ludwigshaven and Leuna, was the largest and most important—concealed documents were uncovered and interrogation of key personnel made with respect to the fuel for the conventional Otto-cycle aircraft engines, fuel for jet aircraft power plants, and fuel for rocket aircraft. All the basic information on these, as they existed in Germany, is now in possession of the Army Air Forces. The exploitation conducted at these objectives indicated that the Germans were more advanced in rocket fuel and chemical supercharging than the AAF, but the material now in our possession is more than sufficient to supply the necessary intelligence on these subjects. A substantial portion of the information on production of aviation fuel and lubricants has already been made available and is in the possession of U.S. agencies and corporations interested in this field.

(3) A document covering a complete source of instruction in the handling of plastic welding, a process which had been employed by the German aircraft industry, was located at Halle. This novel method of fabrication provided for the joining of plastics by flame gas welding and enabled the sections joined together to possess the same strength at juncture as the original material. This information was reported to the AAF for joint study with the Office of Scientific and Research Development.

(4) An acoustic-controlled guided missile research development program, together with operating personnel; was located at Bad Kissingen. The experimental control system developed there contained four electrical circuits that are activated by sound with the intended purpose of launching a rocket-propelled missile into the space occupied by a heavy bombardment formation, and constantly correcting the missile's course by means of incoming sound waves from the aircraft engines. The group of scientists who were engaged upon this development were detained in American custody at the laboratory to develop the program for Allied use.

(5) Athodyd (Lorin Engine) units that developed thrust in excess of 1500 kilograms were uncovered, and sufficient data was in our possession in May 1945 to permit immediate application in the field of high-speed aircraft. production.

(6) High-altitude engine test beds, the most elaborate in the world, which were capable of supplying refrigerated low-pressure air both for engine cooling and combustion, thus simulating atmospheric conditions at approximately 40,000 feet, were found at the BMW plant the largest German plant engaged In manufacturing aircraft engines. The application of these test beds for experiments, intended to assist 'our own manufacturers and thus improve the of efficiency of our aircraft, was initiated at once.

(7) Complete information on the Freya and Reise "G" Wurtzburg and of the Jagdschloss radar equipment was uncovered at the research laboratory located at Koethen.

(8) After the Aerodynamic-Ballistics Research Station at Kochelsee was discovered about 15 May

1945, the Directorate of Intelligence, USAFE, assigned personnel to exploit fully this important target. Over one hundred and ninety German civilian research specialists under their original director, Dr. Herman, continued their work, the results of which, however, were turned over to us More than one hundred detailed reports concerning the station were prepared. The "Kochel Wind Tunnel" located there, had the largest testing sections and the greatest air flow of any known supersonic wind tunnel. It was considered by Army Air Forces of such exceptional importance for research in connection with jet fighter and fighter bomber priority projects that the War Department directed that it be dismantled at once and shipped to the United States. Approximately twenty key German scientists, including Dr. Herman, the director, were removed to America to assist in the reassembling of the tunnel.

(9) Documents of all descriptions and nature were eventually discovered. The records of the German Patent Office, for instance, were found buried 1500 feet underground in a potash mine near Bacha. There were approximately 225,000 volumes, which included secret files. An attempt had been made to destroy them but the resulting explosions brought down a mass of debris which had served to smother the fire. Eventually, the files were evacuated and studied.

(10) Five hundred and eleven microfilm rolls of copies of records of the Oberkommando der Luftwaffe, which was the supreme air force command, were recovered from a mine near Hildescheim where they were hidden. They comprised, for the most part, records of the GAF personnel office, together with statistics on climate at GAF airdromes.

(11) The records of a department of the Speer Ministry, the German Ministry of Production, which dealt with the secret weapons program, particularly V-weapons, rockets and jets, was seized and evacuated through air channels, together with Dr. Rickhei, who was charged with the primary responsibility for the program.

(12) The GAF main equipment depots at Schwein and Kolleda were exploited. The former depot was found dispersed to 53 sub-depots, and although a large proportion of the records was destroyed, sufficient documents were obtained to initiate studies into the GAF system. The Administrative and Quartermaster records of the GAF were recovered from hiding places near Berchtesgaden. The Flying Personnel records, included about 50,000 pilots' qualification cards, together with weather staff records, which were discovered in a swimming pool at Stradtroda. The pilots' cards are of particular value, from an intelligence viewpoint, for future control measures of German air force flying personnel.

(13) Practically the latest type of every German aircraft, some of which never saw combat, eventually were located intact, or a sufficient quantity-of available parts discovered for German mechanics to assemble a certain-type. Usually these were sent across Europe to France, where they were shipped to Wright Field. Occasionally some were flown back. At least one, in some cases as many as ten, of the following, which represent only a fraction of the types, were located, some only after extensive searching throughout Germany, and forwarded to the United States for extended study and development.

> The Messerschmitt aircraft series 1101, 1106, 1110, 1111 and 1112, a series particularly interesting in that it illustrates a phase of coordinated aircraft design into which American aircraft is only now entering; seven rocket-propelled piloted aircraft specifically designed for anti-bomber interception work; a jet-propelled helicopter;
>
> Flettner 282 helicopter;

Horton 9, a flying winged glider;

Ju 88, a radar equipped twin-engine night fighter;

Ju 290, four-engine long range transport;

seven Me 163s, rocket-propelled interceptor fighters;

ten Me 262s, twin jet-propelled fighter-interceptors;

HE-162, single place fighter powered by jet engines;

flying bombs, type V1 single and dual piloted;

Lippisch P-13 Jager, a tailless twin rocket-propelled wing for supersonic speeds;

designs and models of small rocket-propelled piloted aircraft created-for bomber interception work;

three sets of FX-1400, a radio controlled bomb,

and seven complete A-4 rockets (V2s).

Numerous types of aerial equipment and instruments of all models of latest designs were obtained and likewise quickly dispatched for evaluation and study. A specimen of the German secret weapon, the X-4 rocket-propelled, winged, flight-controlled anti-aircraft missile, intended for launching from fighter aircraft against United States heavy bombardment daylight formations, and the new anti-aircraft missile Hs-117, which was launched from the ground, were found and sent to the British Air Ministry for examination.

However great in quantity and extensive in scope the captured equipment, documents, and records of industrial concerns and technical research laboratories were, greater still was the extensive scope of information and salient facts gathered from eminent German scientists, technicians and factory managers through personal interrogations. During the early phase of “OPERATION LUSTY”, ATI teams and skilled American aeronautical engineers and scientists investigating intelligence targets carried out such detailed and extensive interrogations that a wealth of technical information of extreme importance was extricated from brilliant minds once directed to our own destruction. A typical team report submitted after a field trip, vividly illustrates the nature of such interrogations that took place. One team, composed of C. W. Chilson, representing Curtis Wright Company, and E. G. Haven and S. R. Puffer, from General Electric, prepared the following reports after an inspection of the BMW Company and interrogation of their key German personnel:

(a) Outline of Jet Propulsion Development Program Being Actively Followed in Germany.

(b) Outline of Entire Program of Non-Reciprocating Power. Plants Under Development in Germany.

(c) Metallurgical Data Used by BMW on Gas Turbines.

(d) Information on Gas Turbines for Propeller and Jets.

(e) Description of BMW 003 Jet Jumo, Together with the Rocket Assist for the Same Unit.

(f) Description of BMW 801 High Altitude Engine, with Turbo Supercharger and Automatic Control, Together with a Performance Report.

Interrogation reports flowed into the Directorate of Intelligence, USAFE, on such topics as Hollow Steel Jet Turbine Blades, Wind Tunnel Blades, Mica Substitutes, Ceramics, Lacquers, Cements, Buna Rubber, Rocket, Propellants (Fluid and Solid), German Aircraft Engine Types, Safety Fuels, Interferometer Measurements of Pressure Distribution of Wind Tunnel Models, Safety Fuels, Navy Torpedo Models, Temperature Controls on Me Planes, Electrical Controls on Me Planes, Production Design and Manufacturing, Technique Covering Hard Rubber Used in Aircraft Magnetos, Oxygen and Pressurized Cabin Control Equipment. Such reports were immediately prepared and forwarded to Washington for dissemination to various industrial concerns and laboratories for further study and development. Quite frequently it became necessary to keep in custody for extended periods groups of German scientists whose extensive information of the particular subjects precluded the possibility of obtaining for intelligence purposes in one or two interrogations the essence of their knowledge. For this reason, Albert Speer, Director of the German Ministry of Production, together with key members of his staff: Dr. Wurster, designer of the Great Enzian, a rocket-propelled guided missile capable of operating at 53,000 feet with speeds approximating the speed of sound; Professor Willi Messerschmitt; five technical research professors from Darmstad Technische Hochschule; Dr. Alexander Lippisch, who had accomplished important work on aerodynamic designs and supersonic speed flying wings; Dr. Kurt Tank, President and Chief designer of Focke-Wulf; fifteen brilliant scientists and technicians of the Peenemunde Research Institute; and scores of others equally as proficient in their Individual scientific accomplishments, were indefinitely retained for interrogation purposes. When the nature of the work being carried out in German research laboratories was of such vital importance that its completion would materially assist the U. S. Government, moreover, either in the prosecution of the war or in protecting her interests against future aggression, it was found expedient and wise to allow the research professors and technicians to execute their work under American supervision. This was accomplished both in Germany itself and in America, where many scientists were quickly sent during the early summer of 1945. Certain technical objectives, such as The Hermann Goering Aeronautical Research Establishment, the Aerodynamic-Ballistics Research Station, the Aerodynamic Institute & Kaiser Wilhelm Institute, and the Bayerische Motoren Werke, were of such outstanding importance that investigation by specially chosen teams, over extended periods, will be required if everything about them is to be completely exploited.

To catalogue and file the thousands of tons of German documents that were rapidly being discovered throughout the country and then forwarded to one of the three collecting points, the Assistant Chief of Staff (A-2) USAFE, together with the Chief of Technical Intelligence Division, set up in London in June 1945, an Air Documents Research Center, which became the temporary repository for all German air documents. This Center was housed in a six-story building containing approximately 28,000 square feet of usable space. All air documents from the British and American occupation zones in Germany and Austria flowed to this Center. In three months time, alone, over 111,000 tons of such documents were flown from Germany to the Center for processing before being sent elsewhere to one or more agencies interested in the subject.

As the documents poured in, enlisted personnel with a good knowledge of the German language, separated them into technical and non-technical categories. All non-technical documents were then distributed to their proper agencies, while the technical documents received a detailed processing. Each was subsequently catalogued, examined, their worth assessed, and then filed or distributed according to their importance. To assist in the proper screening, it was necessary to prepare a technical German-English dictionary, and a cataloguer's handbook to bring up-to-date the U. S.

Aeronautical Index. Two British agencies of the Air Ministry, A. D. I (K) and A.I.2(g), which were partially housed in the Center, not only met the responsibilities assigned to them by the Air Ministry, but materially assisted in the processing and cataloguing of documents. The U.S. Navy Bureau of Aeronautics also assisted in processing by supplying personnel, microfilm equipment and operators, and film-processing facilities, while twenty-five prominent American scientists and aeronautical engineers, such as Jean Piccard and Dr. John Akerman, University of Minnesota, Dr. Ernest Robischon, California Institute of Technology, Dr. Paul E. Hemke, Rensselaer Polytechnic Institute, and Dr. Richard Hartenberg, Northwestern University, acted in a consulting and advisory capacity. Individual unit libraries within the Center were set up to handle documentary material belonging to giant German concerns. Such libraries existed for the Messerschmitt Company, the ZBW, an organization which existed in Germany for the cooperation and dissemination of all formal technical aeronautical reports, the BMW, the Daimler-Benz, and others. Libraries, as well as sections, were set up to file documents of similar technical nature, such as Aircraft, Armament, Engines, Turbines and Propellers, Electronics, Rockets, Jets, and Guided Missiles. Once the documents were indexed and given a permanent library number, the laborious job of microfilming everything of importance, needed both in England and America, took place. The positive copies of the original microfilms were then sent to U. S. Army Air Forces, U.S. Navy, and British Agencies for further distribution. That which did not lend itself to reproduction by-this method was either photographed, photostated, or blueprinted. Eventually, a German Technical Air Documents Card Index will be prepared and copies distributed throughout Gt. Britain and the United States to Using Agencies, which include the aeronautical industry, government agencies, research establishments and educational institutions. At present, there are two hundred of these using agencies in the United States alone that have already made extensive use of captured German technical information gathered originally by ATI teams-from industrial firms, research institutions, and universities in Germany.

Non-technical documents after leaving the Documents Center were delivered to a combined research agency of USAFE, and Air Ministry known as "A.I.12/USAFE". This section was created in the fall of 1944 to meet the requirements of Post Hostilities planning staffs, and in anticipation of Air Intelligence requirements for the disarmament and demobilization of the German Air Force, as well as a comprehensive long range study of all phases of the GAF. The library on the German Air Force that had slowly been built up by British specialists and American officers under the Directorate of Intelligence, USAFE, prior to "OPERATION LUSTY", became suddenly augmented to such an extent by quantities of documents located by ATI teams that the staff of officers and enlisted men had to be substantially increased. In spite of the tremendous work involved—cataloguing, microfilming, photo-stating, translating, and preparing detailed library lists and reports for dissemination to interested agencies—the staff handled the work in a thorough and expeditious manner. By the time the first Air Force officers arrived from the United States in June to prepare staff studies on aspects of the German Air Force, practically all of the necessary material had been collected and catagorized so that work could immediately. commence.

Eventually, over two hundred officers, chosen, for the most part, by Hq Army Air Forces, from various air force commands in the United States, were engaged in scholarly research to fulfill their assigned requirements. Working from offices located in London and under the direction and guidance of the Assistant Chief of Staff A-2, USAFE, the officers exploited every available pertinent document located in repositories in London, A.I.12/USAFE, Air Documents Research Center, British and American Navy and Army libraries, and the British Museum. It was soon discovered, however, that in spite of the tremendous quantity and excellent quality of captured material available, too many questions remained unanswered and too many enigmas concerning various aspects of the enemy's air force unsolved. It became imperative, consequently, for field trips to be made into Germany in an attempt to fulfill the exact and comprehensive requirement's laid down, not only by Hq Army Air Forces, but by the staff officers themselves, who, through a desire to accomplish a superior research job and obtain for future-reference every iota of information relative to their enemy's strength, weakness, and ambitions of the past and future, refused to satisfy themselves with incomplete answers and results.

Officers preparing a study of German Air Defenses visited the Flak defenses at Bremen, Hamburg, Munster, Nuremberg, and Augsburg, interrogated General von Axthelm, Chief of German Air Force flak units, and his staff, as well as members of various flak organizations, such as the 8th Flak Division, and 8th Flak Brigade. A detailed study was made of the Air Force at Grove, Denmark, where a complete fighter defense installation was captured intact with plotting center and all-key personnel necessary for its operation. Similarly, officers preparing other staff studies made trips that took them as far south as Austria and as far north as Norway in their quest for the desired facts and figures, inspecting supply dumps, aerodromes, and other installations and interrogated appropriate German P/W officers located both in British and American zones.

Most of the detailed interrogations conducted by staff study offices were of members of the German Air Ministry Staff (OKL), which had been captured and held at Berchtesgaden as a combined USAFE/Air Ministry intelligence exploitation target, and of high ranking German army officers detained in P/W cages. When it became evident that many such interrogations would be necessary to fulfill the requirements, the OKL party was removed in toto to a camp close to London. Similarly, important German Ground Officers were likewise sent to England to further the project. Hundreds of detailed interrogations were conducted. To enumerate such German Officers interrogated would be comparable to listing a roster of the German Air Force. The following, most of whom were high ranking officers, is illustrative of the scope covered:

Reichsmarshall Goering.

Oberst von Brauchitsch, Goering's Aide.

General der Flieger Koller, Chief of General Staff.

Major Hermann, Administrative Officer.

Oberst Wolter, General Koller's advisor.

General Maj. von Rohden, Historian of the GAF.

Min. Dir Dr. Benkendorf, Chief Meteorological Service.

General Martini, Signals.

General Lt. von Criegern, General Quartermaster.

Oberst Fritz Nebel, ZRadar Inspector.

General Maj. Hitschold, Chief Ground Attack Operations.

Generalleutnant Galland, Chief Fighter Operations.

Generalleutnant von Massow, Gen. der Fliegerausbilding.

Gen. Oberstabsarzt Dr. Schroeder, Medical Services.

General Maj. Morzik, Luftransport Chef der Wehrmacht.

General Lt. Dahlmann, Flying Safety.

General Galland, a 33-year old flyer, who received his first battle experience in Spain and who has obtained a reputation among Allied officers as perhaps the most brilliant general in the German Air Force, prepared an historical narrative of fighter tactics employed for all campaigns, beginning with the Spanish and ending with the last concerted attacks against Allied fighters and bombers in 1945. This included, in part, a rather comprehensive history of the GAF. General von Rohden and his assistants, under the direction of the historical section, USAFE, prepared a lengthy dissertation on the history of the German theories of the application of air power. General Marzik and his assistants wrote up every airborne ' campaign the Germans had executed, or planned, such as the air invasions of Malta and England. Similarly, to satisfy the Post Hostilities requirements, German officers prepared detailed treatises on every topic intelligence officers wished discussed: medicine, training devices and procedures, weather, flak defenses, fighter defenses and attacks,. photo intelligence, provost marshal system, methods used to evade the Treaty of Versailles, methods used to indoctrinate Nazi principles in the Luftwaffe, and many others.

The first staff study prepared in compliance with the Air Force Post Hostilities Requirements was finished on. the 12 August 1945, the last on January 3, 1946. The list of scholarly studies below, comprising forty-five thick volumes, includes, it is reasonable to state, far more information concerning the German Air Force than the Germans themselves had ever collected during the war:

Communications.

Aviation Medicine.

Flying Safety.

Inspection.

Provost Marshall.

Personnel Administration.

Supply.

Maintenance.

Patent Activities.

Air Defense.

Propaganda in the Luftwaffe.

Records & Reports System, Statistical Controls & Planning Methods.

Tactical Employment: Liaison Operations.

Troop Carrier Operations.

Tables of Organization and Equipment.

> Coordination between the GAF Air and Ground Forces. Controlled Missile Program.
>
> Night Fighter Operations.
>
> Emergency Sea Rescue.
>
> Fighter Tactics employed against Allied fighters, fighter bombers, and heavy bombardment formations.
>
> Photo Intelligence.

Copies of these reports were given to the British Air Ministry and disseminated in America to every interested military command. They will eventually be studied in Staff and Command Schools and the War. College, and may serve as a nucleus for future historians interested in the aerial aspects of the second World War, or, in particular, of an air force once reputed to be the greatest and most efficient ever assembled. The military mistakes made by German Air Force generals, the clash of strong personalities that was so detrimental to their cause and purpose, the magnificent military plans created but never executed, tactics employed, principles of air power devised and used, adopted method of communications, supply, and training, are all lucidly and scholarly presented. In these documents lies the essence, so to speak, of a once sinister and destructive force now so hopelessly crushed that its rebirth appears highly improbable.

“OPERATION LUSTY” is now dead. No longer do ATI teams scour the German countryside exploiting intelligence targets. This work has been completed. The requirements, both technical and non-technical, have been fulfilled: equipment and documents of immediate interest and value to technical research centers in the United States for evaluation and immediate execution towards the war against Japan was expeditiously collected in the early weeks of the project’s existence; Air Staff Post Hostilities Intelligence Requirements were fulfilled; equipment and documents were sent to technical research centers for extended periods of study and development to increase the efficiency of United States aircraft, equipment, and research establishments. There still exists however, strict supervision of eminent German scientists and their assistants, and corporation directors and managers, technical workers, and university professors, who were once employed in scientific research. Many of such personnel are still actively engaged both in the United States and Germany in the furthering of inventions, technical discoveries and formulation of new scientific processes that they were doing directly or indirectly for the German government when hostilities ceased. Certain important corporations such as those previously mentioned, moreover, are still working though the war had never ended; the results of their labors, however, now benefit the United States rather than Germany. If necessary and advantageous, this aspect of exploitation will continue indefinitely. The results that have already been obtained and those that are certain to appear in the immediate future, compensate over and again for the time, effort, and money expended in extricating from the brains of brilliant German scientists every particle of information and knowledge they possess that in any way further the interests of our government.

Nazi Technical Papers Form Research File: Captured Documents Provide Complete History of Air Program. *The Lima News* (Lima, Ohio) 21 November 1947 p. 12.

DAYTON, Nov. 21—(AP)—Any student who ever tried to wade thru just a single page of German translation will appreciate this one:

What were once 1,500 tons of German documents—a complete history of the Nazi air research program from 1933 to 1945—have been evaluated, classified, catalogued, indexed and published in microfilm by air intelligence experts at nearby Wright field.

As a result, American aircraft industries have at their call products of the most intensified aeronautical development program the world ever has known.

Engineers estimated the actual research contained in the captured documents would cost between two and three billion dollars if reproduced today in this country.

The air documents division of the AAF air materiel command's intelligence department discarded 1,450 tons of lesser papers at the beginning of project index. But it handled 55,000 Nazi documents, all written in technical German and using at least 110,000 new German aeronautical terms familiar only to German scientists.

Included were tons of top secret details on the world's first production jet-engine fighter, the Messerschmitt-262; design, production and test information needed to duplicate the deadly V-1 and V-2 missiles, plus hundreds of other ideas ranging from swept-back wings for supersonic flight to formulas for making heat-resistant dyes and synthetic rubber for airplane tires.

Moving spirit behind the job has been a young AAF officer, Col. H. M. McCoy, West Point graduate and holder of two graduate degrees from the California Institute of Technology.

It was McCoy who evolved what seemed a fantastic idea in 1945 when the project actually got down to the work of abstracting and filing.

Colonel McCoy wanted to catalog German documents so they would form a nucleus of a huge file embracing the entire science of aeronautics, a ready-reference catalog which would save millions of dollars and hundreds of thousands of man-hours by avoiding duplications, costly literature searches and wasted efforts.

Suppose an American firm wanted to begin research on a particular type of guided missiles without having previous experience. Suppose that company went thru months of study and costly experimentation, only to find near the final test stage their missile already had been tried elsewhere and found impractical.

With an air catalog such as McCoy envisioned, the firm could have turned to a central government agency before experimentation began and learned the idea was impractical before they wasted time and money.

Colonel McCoy's index dream is in process of being realized. The Institute of the Aeronautical Sciences, under joint Air Force-Navy contract, is compiling the standard aeronautical index, considered the most radical innovation in classification history.

Wright field is serving in a similar manner with its German information. By August, 1947, the air documents division had furnished more than 10,000,000 index cards from its master file to 35 qualified government, scientific and industrial organizations thruout the nation, plus hundreds of thousands of documents in microfilm to 2,500 governmental agencies and contractors.

All captured Nazi documents are microfilmed. From its index, a qualified organization need only ask for a copy of a needed document.

Within 48 hours the requested document is on its way. In an emergency, that time can be cut to a few minutes.

E.2 Advanced Liquid Propellant Rockets

[Official histories acknowledge that Germans designed a two-stage liquid propellant intercontinental ballistic missile, A-9/A-10, during the war, but state that the project never progressed further. For example, Michael Neufeld, Senior Curator at the Smithsonian National Air and Space Museum, wrote: “The A-9/A-10 was never more than a drawing-board concept and was shelved in 1942” [Neufeld 1995, p. 283]. Neufeld also wrote that it was not possible to upgrade single-stage rockets during the war: “Emergency improvisations had less of an impact on the A-4, because its relative technical maturity puts limits on how much further improvement could be extracted in a short period of time” [Neufeld 1995, p. 251].

This section presents evidence that the A-9/A-10 rocket was much more than a paper design, as well as evidence for other wartime work on advanced liquid propellant rockets:

- There were several reports of upgraded wartime A-4 rockets that apparently had been lengthened (and therefore carried more propellant and presumably had higher-thrust engines to compensate) from the standard 14 meters long to 18 or 21 meters, and German teams in the United States, Soviet Union, and France readily built such upgraded versions after the war (pp. 5794–5799).

- David Irving wrote of the giant underground rocket launch complex that Germany built at Wizernes, France during 1943–1944: “The remaining site, at Wizernes, caused some anxiety, as it was not obviously aligned on any city in Europe. One interpreter caused a high degree of alarm early in the year when he discovered that one facet of the workings was within half a degree of the accurate Great Circle bearing on New York. [...I]t is a remarkable fact that the enormous bombproof doors and handling gear were all capable of handling a rocket about twice the height of the A 4[...]” (p. 5311).

- A 26 October 1944 U.S. report derived from a German prisoner of war indicated that there were advanced rocket installations near Erfurt, that two-stage rockets had already been tested up to a maximum altitude of 360 km, that an upper-stage rocket engine had successfully used liquid hydrogen and liquid oxygen, and that research was being conducted on ion rocket engines (p. 5311).

- In July 1944, U.S. Army Air Forces General Henry Arnold stated that the Germans were currently developing “large 75 ton rockets,” over five times the weight of an A-4 (V-2) rocket (p. 5316.

- A 14 December 1944 U.S. report derived from another German prisoner of war stated: “Two types of V-2 have been built: Type A 1, which is about 23 m long and 4.5 m in diameter, and Type A 4, which is about 18 m long and 2.5-3 m in diameter. Only the latter is in mass production... PW heard that German technicians intended to launch them to an altitude of 120 km, which would have permitted them to reach NEW YORK.” The description of the first type does not match the very small and decade-old A-1, but does match the A-10 if a “0” was dropped somewhere along the way (p. 5334).

- On 5 January 1945, Colonel Lowell Weicker at the Headquarters of the U.S. Strategic Air Forces in Europe wrote: "Germany... is leading the world... in long range missiles... A large part of her manufacturing facilities have gone underground and she is bending every sinew for the last stand on the Vaterland frontiers" (p. 5336). A 19 January 1945 report from the Headquarters of the U.S. Strategic Air Forces in Europe further stated: "The V-2, or rocket projectile, with a warhead of approximately one ton, and a current range of 225 miles, is being fired at London at the rate of 180/250 per month, and against Continental ports at the rate of approximately 300 per month... Larger rockets (68 feet in length as against 45 feet) are known to exist, and may appear in small quantities during the year. They would have a considerably larger warhead." The larger rockets "known to exist" sound like an enlarged V-2/A-4 or an A-10, despite the conventional historical narrative's denials of both possibilities (p. 5337).

- According to numerous press accounts on 26 January 1945, the German "head of an experimental station for V-bombs in Jutland" had just defected to Sweden and revealed that the V-3 was "an improved version of V-2," and the V-4 rocket, which could reach New York and other eastern U.S. cities from Europe, was "now in production" (p. 5341).

- In a transcript of her testimony before an East German government inquiry on 16 May 1962, Cläre Werner, a wartime lookout at the Veste Wachsenburg castle near Ohrdruf, reported watching the launch of a large new type of rocket on 16 March 1945 near Rudisleben, as well as being informed of the historic nature of the launch by visiting military and SS officials (p. 5344). In transcripts from the same 1962 East German inquiry, three witnesses (Werner Kasper, Albin Kummer, and Alfred Gründler) who worked at the Rudisleben complex reported seeing the 16 March 1945 rocket prior to its launch and described it as a two-stage rocket over 30 meters tall and over 4 meters in diameter at the base (pp. 5344–5347). Several U.S. intelligence documents mentioned the existence of very large military complexes at Rudisleben and Ichterhausen (pp. 5348–5351).

- In his 1995 autobiography, Otto Skorzeny, who had been a very prominent SS officer during the war, wrote: "Included in the V-weapons program was the construction of a rocket capable of bombarding New York or Moscow. This rocket was practically finished at the end of March 1945 and could have gone into series production beginning in July" (p. 5352). In his 2000 autobiography, U.S. "Mercury Seven" astronaut Gordon Cooper said that Wernher von Braun and his fellow team member Joachim "Jack" Kuettner had privately told Cooper that shortly before the end of the war, Germany had fully prepared a manned rocket capable of reaching New York (p. 5353). In 2000–2002 interviews, Heinrich Himmler's chief adjutant, Werner Grothmann, stated that prototypes of the two-stage "America rocket" were completed during the war, and that a prototype of some sort of large rocket was successfully test-launched on 16 March 1945 in Thuringia (pp. 5355–5359).

- Henry Picker, a close confidant of Hitler, wrote that before the war ended, prototype fission bombs and prototype A-9/A-10 intercontinental rockets were completed and ready, and that facilities for mass-producing the bombs and rockets had been built (pp. 4635–4639).

- A 7 April 1945 U.S. Army report stated that a German prisoner of war "was told by an ordnance man stationed at OHRDRUF that from here a new secret wpn will shortly rise (wird steigen)" (p. 5363). A 9 April 1945 U.S. Army report stated that near Ohrdruf was a large "underground plant. French workers... were escorted by armed guards, not allowed to look right or left... considered to be very important production area" (p. 5363).

- Several 8 April 1945 U.S. Army intelligence documents reported: "...underground factory ... employs some twenty to thirty thousand Russians, Poles, French, etc. They are making the V-4, which is a two man rocket of some sort... weapon then is sent to Weimar..." Another report from the same date clarified that the "gadget holds 2 men" (pp. 5365–5373). 18 April 1945 articles in French and British newspapers gave the accounts of French workers who had just been released from a 24-square-kilometer underground factory, where they had been building V-4 rockets. They also mention that the V-3 was a known, improved, and enlarged version of the V-2 (p. 5376–5377).

- Captain Heinz Stoelzel, a close associate of Wernher von Braun and Walter Dornberger at Peenemünde, was apparently relocated to near Erfurt, Thuringia no later than 3 November 1943, and fled to Switzerland at the end of the war to avoid Allied capture. Shortly after the war, he hand-copied detailed drawings showing the planned A-9/A-10 trajectory to New York and the design of an A-9 with a two-man crew to pilot it to its target. Most of his papers were destroyed after his death, including any information on the A-10 he may have had (pp. 5384–5388).

- A Russian description of German technology captured in 1945 showed a diagram of a complete A-9 upper stage on an A-10 lower stage (p. 5389). At least two A-9 or A-4b rockets were test fired without the A-10 booster in December 1944 and January 1945, and more A-9 rockets were known to have been built (p. 5390). According to a 1947 U.S. Army Air Forces report, one of the German scientists employed in the United States after the war had been developing "a guidance system for the transoceanic A-10 surface-to-surface missile when the war ended" (p. 5398).

- In a 13 May 1945 speech, Winston Churchill said: "When the Americans captured vast stores of rockets of all kinds near Leipzig, ...and when all the preparations being made on the coasts of France and Holland could be examined in detail ... only just in time did the Allied armies blast the viper in his nest. Otherwise the autumn of 1944, to say nothing of 1945, might well have seen London as shattered as Berlin" (p. 5398). Newspaper articles from 14 June 1945 reported that according to Allied investigators and German scientists, 3000-mile-range rockets would have been mass-produced by fall 1945, or even sooner if Allied bombing had not delayed the program (pp. 5402–5403).

- On 26 June 1945, Henry Fowler, Director of the Enemy Branch of the U.S. Foreign Economic Administration, testified to a U.S. Senate committee: "According to recent reports from Germany, it appears that if the Germans could have held out only 6 months longer they would have been able to smash New York City with improved V-2 bombs... It is not necessary here to elaborate upon the terrifying scientific discoveries which our economic and industrial intelligence is gradually uncovering as we work beneath the lid in Germany. With the memories of her new V-weapons fresh in our minds, little needs to be added except to point out that they just didn't appear out of thin air." It would be impossible to go from paper plans to deployed intercontinental ballistic missiles within six months, so the rockets must have been far beyond the paper design phase in May 1945 (p. 5206).

- On 27 August 1945, Consolidated Vultee Aircraft Corporation (Convair) stated in *Life* magazine: "Especially in the last months of the war, our margin of safety was slimmer than most of us suspected. Just how slim it was is known best to certain American military experts who have since inspected some of Germany's underground research laboratories and war plants. Here they saw secret weapons in various stages of development... weapons which might conceivably have turned the trick for the Nazis if they could have used them boldly in a last desperate gamble. Some of these things can now be revealed. Others cannot—yet... In a V rocket plant, burrowed 800 feet deep in limestone rock, our technicians found blueprints for a fearful V bomb with an estimated range of 3000 miles. 'We planned to destroy New York and other American cities starting in November,' said a German rocket engineer" (p. 5208).

- On 29 August 1945, Secretary of the Navy James Forrestal announced that Germany had been actively developing "at least two or three rockets which represented advances over what we call V-2" (p. 5441–5443). A 15 September 1945 U.S. intelligence report stated that "experiments had already been conducted on piloted models" of long range missiles, and that the missiles were intended to carry atomic explosives (p. 5444–5445).

- In October 1945, U.S. Army Air Forces General Henry H. Arnold testified to Congress that "German V-2 bombs alone, perfected with wings, radar and electronic devices, can now travel over 3000 miles and at 2000 miles hit a target on the button" (p. 5454. In December 1945, U.S. Army Air Forces General Carl Spaatz wrote regarding rockets: "The Germans were readying a transatlantic model when the war ended" (p. 5465). In General Arnold's 1949 autobiography, he wrote: "The V-10 (A-10), a very large rocket intended especially for New York, was being built" (p. 5466).

- In November 1945, numerous newspapers reported that a Swedish spy who had been working undercover in the German rocket programs provided detailed evidence that Germany had been developing the "V-10, which... was to cross the Atlantic in thirty-five minutes and devastate American industries and cities," and also "it should be possible to cruise around in space under human control" (p. 5458–5459).

- In a 7 March 1946 presentation to the Society of Automotive Engineers, U.S. Army Air Forces Colonel Donald L. Putt, who was in charge of the aerospace engineers, documents, and prototypes brought back from Germany, stated: "The Germans were preparing rocket surprises for the whole world in general and England in particular, which would have, it is believed, changed the course of the war if the invasion had been postponed for so short a time as six months... The most highly publicized missile of the Germans was the V-2, or as the Germans themselves knew it, the A-4. There were 10 variations of this weapon... Three were prototypes. Four were improved models. One was a launching device intended to increase the already great range to 5000 km. Interestingly enough, one of the improved models was to be equipped with wings, wheels, a pressurized cabin, and to carry a pilot" (p. 5472).

- A U.S. Army card catalog of intelligence documents shows that the U.S. government once possessed a complete history of the A-9/A-10 trans-Atlantic rocket, written two years after the war's end, but that this history was either destroyed or not transferred to NARA with the other files; no copies of this report have ever been located. If the A-9/A-10 never entered active development during the war, why would the U.S. government have commissioned a detailed history of its development in 1947, and why would the government have later ordered that history to be suppressed? Does the fact that the Army Assistant Chief of Staff for Intelligence specifically filed this report under "Nuclear Physics (Atomic Energy)—Uses" indicate that the A-9/A-10 had a nuclear warhead (p. 5485)?

- In December 1946, many newspapers reported that Wernher von Braun said that before the war ended, he and his team had been developing a rocket with a launch mass of 100 tons (approximately seven times larger than an A-4 or V-2 rocket) that was specifically designed to carry a mysterious explosive payload of six tons from Germany to the United States (pp. 5496–5497). A six-ton payload would have been beyond the capability of even an A-9/A-10, so was this an even more powerful rocket? Why was it so important to carry a six-ton payload? Even a fission bomb would be smaller. Was the intended payload a hydrogen bomb?

- A number of 1945–1947 U.S. intelligence reports indicated that Soviet forces had restarted production in German rocket factories including wartime rocket factories in the Erfurt area, plants producing hydrogen as well as oxygen, and factories producing manned A-9 rockets apparently manned. The reports also mentioned rockets called the V-3 and V-4 that were larger than the V-2, had longer ranges than the V-2, and were successfully produced in Germany and/or Bohemia during the war. From the described dimensions, these V-3/V-4 rockets were apparently not the A-9/A-10, but rather some roughly comparable long-range rockets that had been designed and produced in parallel with the A-9/A-10 (pp. 5503–5572).

- A 1957 U.S. Air Force report stated: "A program known to the Germans as the A9/A10 development was designed to use a winged V-2 rocket as the second stage of a two-stage system. This vehicle was under development and test by the Germans when the war ended" (p. 5603).

These large wartime liquid propellant rockets and their creators led directly to the postwar development of large liquid propellant rockets in Allied countries, including modern intercontinental ballistic missiles (the second component of the nuclear triad) and launch vehicles for satellites and spacecraft.]

Ernst Klee and Otto Merk. 1963. *Damals in Peenemünde—Ein Dokumentarbericht.* Oldenburg: Gerhard Stalling. p. 99

Die Interkontinentalrakete, heute eine Selbstverständlichkeit, schwebte den Peenemünder Wissenschaftlern und Ingenieuren bereits 1940 vor—lange, ehe das Aggregat 4 überhaupt flog. Aus ersten Überschlagsberechnungen entstand das Projekt A 9/10, dessen hier wiedergegebene Zeichnung vom 10. Juni 1941 stammt. Das gesamte zweistufige Aggregat hatte ein Höhe von 26 Meter, war also größer als die heutigen amerikanischen ICBM. Das Startgewicht sollte 85.3 Tonnen betragen, wovon auf die zweite Stufe—eine ungeflügelte oder eine geflügelte A 4—16.2 Tonnen entfielen. Flugbahnberechnungen, die man damals anstellte, deuten darauf hin, daß man mit einer weiterentwickelten zweistufigen Kombination von West-Frankreich oder Portugal aus über den Atlantik hinweg Nordamerika zu erreichen hoffte. Da man jedoch nur einen Sprengkopf von 925 Kilogramm hätte befördern können, wäre dies militärisch ein ziemlich sinnloses, weil zu aufwendiges Unterfangen gewesen—höchstens geeignet, einen moralischen Effekt zu erzielen. Aber wie bei allen Projekten kam es den Peenemündern auch hier nicht unbedingt nur auf die Waffe an. Daß sie die ersten waren, die den Gedanken einer von Kontinent zu Kontinent fliegenden Rakete faßten, bleibt ihr Verdienst.

The intercontinental rocket, today a matter of course, was already in the minds of Peenemünde scientists and engineers in 1940—long before the Aggregate-4 even flew. The first estimated calculations resulted in the project A-9/A-10, the drawing of which shown here [p. 5271] dates from 10 June 1941. The entire two-stage aggregate had a height of 26 meters, which was larger than today's American ICBM. The take-off weight was to be 85.3 tons, of which the second stage–an A-4 without or with wings—comprised 16.2 tons. Flight trajectory calculations made at the time indicate that a developed two-stage combination could hopefully travel from Western France or Portugal to North America across the Atlantic. However, since only a 925 kilogram warhead could have been carried, this would have been a rather pointless military endeavor, as it would have been too costly—to achieve an effect on morale at most. But as with all projects, the Peenemünde people did not necessarily only care about the weapon. That they were the first to grasp the idea of a rocket flying from continent to continent remains their credit.

4. WEFA (Wehrmacht FahrtCoy)

Because transportation of vital and urgent deliveries to war industries by RR was becoming increasingly hazardous, eleven WEFA (Wehrmacht FahrtCoys) were organized to take over some of the loads previously hauled by RR.

1, 2, and 3 Coys had 110 men and 23 8,000 liter petrol tank trucks. Trucks were camouflage-painted. Coys hauled petrol from producers to secret dumps and from dumps to industrial and military consumers.

Coys 4-11 each had 50 hy trucks. They were employed in hauling half-finished parts and finished products for the automotive and aircraft industry, and occasionally for secret weapon plants.

WEFA covered all of Germany. Its principle was to make the most economical use of time and space by avoiding every empty mile.

(Source: Gefr Peter HERZOG 11 WEFA Coy captured 28 March WALSUM)

5. V-2 Organization

Preamble

Four PWs, members of the HQ having administration over launching of V-2, were interrogated separately and IO is satisfied of their sincerity.

The four PWs belonged to 1191 Nachrichten Abteilung, the liaison and message unit of Div z V. They left the Div CP in a Volkswagen and travelled appr 100 km to the Allied lines in order to surrender, 1800 hrs, 2 April at FRECKENHORST. PW SAUER was an exchange operator and supervised teletypes. PW FISCHER and PLUM were teletypists. PW NOACK was a teletype mechanic.

Organization

The purpose of Div zV (sic) was the construction, supply, and administration of V-2 launching sites. The preparation for the use of V-2 was done by 191 HARKO, Genmaj METZ prior to 8 Sept 44. The HQ of 191 HARKO was in MESNIL-LE-ROI nr ST GERMAIN and in MAISON LAFITTE (PARIS District). It later moved VILLAINES, LILLE, and finally to GHENT. All four PWs came to 191 HARKO, March 44, when 724 Nachr Coy (mot) was enlarged and reorganized to form 1191 Nachr Abt (mot). Div zV consists of 485 Arty Regt, 300 SS Werfer Tp, 1191 Nachr Abt, and Sicherungs Gruppe HEISTERMANN under Hptm HEISTERMANN (assigned to div later than other units). The Arty regts have an HQ Tp and 10-12 launching tps. March 45, the Arty regts changed their numbers... 485 became 902 Arty Regt zV, and 836 became 901 Arty Regt zV.

5. V-2 Organization (Continued)

Genmaj METZ was removed after the launching of the first V-2, 8 Sept. He was blamed for the fact that preparation had been too slow and that his officers spent their time in PARIS, instead of at their duties.

On 26 Jan 45, 5 Flak Div (GAF), which handled V-1s, joined Div zV with the consent of GÖRING. Both units remained as separate entities, but were subordinate to a new higher HQ (formed 26 Jan) AK zV, which had its HQ in HAXBERGEN nr HENGELO. It later moved to vic WIEDENBRÜCK and finally BAD ESSEN.

Area of Sites

836 Regt (later 901) was known by the code name of "Gruppe SÜD" and had its sites nr ALTENKIRCHEN, and nr EUSKIRCHEN. 485 (later 902) Regt was called "Gruppe NORD" and had sites in the area of BURGSTEIN-FURTH nr the Dutch border. Part of 485 Regt, called "KG Holland" had sites nr UTRECHT.

Reorganization

Appr 25 March 45 an order appeared preparing Div zV for committment as Inf. Gruppe SÜD was issued Inf equipment and although still under the administration of Div zV was committed as Inf. Shortly before Easter, KG Holland and Gruppe NORD were withdrawn and committed as Inf for the defense of the WESER sector. Two-three Schiesszüge had to remain fully equipped (in 902 Regt) after 30 March in order to be ready to resume launchings should the tide of battle turn. V-2 launching equipment had to be destroyed or used as tk obstacles. 28 March an order appeared subordinating the whole AK zV to the Reichsführer der SS.

HQ of 5 Flak Div, Div zV, and AK zV had to move to SOLTAU (S end of LÜNEBURGER HEIDE), 1 April, to await further instructions.

Flight of PWs

All four PWs together with O/Gefr PUHL (son of Vice Pres of Reichsbank) were on duty, night of March 31-April 1. Men of the Signal Bn had been discussing desertion to the Allies because of the hopelessness of the situation and because of the commitment of the Div as SS Inf. The SS "big shots" were planning a last stand if Germany were defeated, and PWs wished no part of it, therefore they planned to break away from the convoy which was to leave the following day. However, on the night of 31 March, upon learning that an officer was to ride in their shop truck, they decided to leave. They printed false trip tickets, took a Volkswagen and drove W. They waited in a farm vic FRECKENHAUSEN for the arrival of the Allies.

At NIJMEGEN, at the time of the Allied Para invasion, Uffz RISCH and O/Gefr KOIDL of the Medical pl of HQ dressed as civilians in order to desert.

Production of V-2

All V-2 production plants bear code names. The main assembly, as far as PWs know was in the SAARGEBIET. Another chief place of production was in the THÜRINGEN Forest in a factory referred to as MUNHAUSEN". On 31 March, an order was sent by KAMMLER via teletype: 'In Anbetracht der Lage ist sofort die Produktion von V-1 und V-2 vorüber gehend einzustellen. Die

Launching of V-2

The OC regt determined when and how often to fire V-2s. All available V-2s were fired as soon as they came from the factory. Launching did not go on during air raids. 1 hrs preparation was required for each launching. In case of England, V-2s were aimed only at Greater LONDON. They had a dispersion of 9-11 km.

A total of 3,050 V-2s were launched from the beginning of their use 8 Sept 44-30 March 45. PWs state that this figure was commonly known among HQ personnel.

The main difficulty encountered in the launchings was the lack of A-Stoff, which became increasingly evident, Feb 45. After a conference at HIMMLER HQ, it was rumored that enough A-Stoff had been consigned to Gruppe NORD to last until Autumn 45.

V-2 against the REMAGEN Bridge-Head

KAMMLER, OC of AK zV and Div zV, insisted on using V-2 against the Allied REMAGEN bridge-head. Gen JODL was against this because of the wide dispersion. However, KAMMLER persuaded HIMMLER and ten V-2s were fired on the day during which the bridge collapsed. KAMMLER boasted that a V-2 had struck the bridge causing it to collapse.

Reports on Effect

Reports on the effects of V-2 were obtained from agents in the target-cities. "Erfolgsmeldungen" came from LONDON to Funkstelle HAMBURG and were forwarded by teletype to AK zV and Div zV. Occasionally reports were sent to OKW, BERLIN, and from there forwarded to the V-2 HQ.

O/Lt LEONHARDI (or LEONARDI) became Ic of AK zV, 26 Jan. He was formerly IC of the Div. He is an elderly Arty Reserve officer and Dr phil who speaks English and was said to have been in England. Since his promotion messages have come direct to HQ AK zV.

Erfolgsmeldung consisted of a heading giving the name of the wireless receiver (Hambufg), and a message: "Erfolgsmeldung from V-Mann Whiskey Flugzeug-Monteur LONDON. Date.....Hr.....location of hit (Street, Garden, District), number and kind of casualties, damage and description of crater. "Whiskey Flugzeug-Monteur" was one of many code names or numbers used by agents. Occasionally a short remark of reliability of the V-Mann appeared at the end of the message. At times reports contained only estimates because agent was unable to go near crater or could not obtain accurate figures of casualties. PWs saw reports from

5. V-2 Organization (Continued)

"Whiskey", LONDON as late as end Jan 45. PW could not estimate time required from the time the bomb was launched until a report was sent back.

Similar reports on hits in ANTWERP were reported promptly by Belgians or Frenchmen. One report seen by PW described a hit on a cinema or theater in ANTWERP. PWs did not recall having read any reports of hits on LIEGE. A report from England described a hit nr a large hotel or restaurant containing many mirrors, in LONDON.

When asked, all three PWs state definitely that O/Lt HEMMERS, O/Lt LEONHARDI, and perhaps Lt KIESO were in touch (they do not know direct or indirect) with V-Männer. They remember two instances: one in Dec or Jan (not later than 26 Jan) O/Lt LEONHARDI asked urgently from Reichsbank in BERLIN for 5,000 RM in dollars. Then O/Lt LEONHARDI ordered a car to go "nach oben" (Holland) through BURGSTEIN-FURTH, the HQ of 902 Regt, to meet the V-Mann or a Vermittler and to give him the 5,000 Mark in dollars as the V-Mann had been bombed out in ANTWERP by a V bomb.

The second episode occured after 26 Jan (second half of Feb 45). PW read a teletype message sent out on behalf of Lt HEMMERS then Ic Officer of Div z V (Former Ic of Flak Div 5) ordering urgently a "schnelles Englisches Flugzeug." Luftflottenkdo WEST answered that a plane was ready at FLUGHORST DUISBURG and to be identified and used by an officer giving a code number and asking for the plane by code number and for the pilot by code name. Lt HEMMERS left HQ on that day and was not seen again up to time of PWs' desertion.

Security Among V-2 Personnel

All men received a series of lectures on security from O/Lt LEONHARDI. Lt KIESO had to sign a declaration 4 times a month stating that men were keeping all their activities secret. They were instructed to tell civilians that they were an Auffangsstab for motorized units. Mail was censored by special censors.

Personalities:

METZ	Genmaj	Former OC 191 HARKO
KAMMLER	Obergruppenführer	OC AK zV and Div zV, ruthless, bloodthirsty, a close friend of HIMMLER (or in any case of HIMMLER's aid Obersturmmann GROTMAN)
THOM	Obst	V-2 specialist, became acting OC of AK zV and Div zV when KAMMLER moved to BERLIN
SCHMIDT	Obersturmführer	Temporary acting OC of AK zV and Div zV, sent to "MÜNHAUSEN"
HOHMAN	Obst	Important in V-2 development, sent to E front (until March 45)
MIESEL	Stufmführer	Ia Div zV
PLÖTZ	Maj	Predecessor of MIESEL
GERHARDI	Hptm	" " "
WOLF	Obst	OC 5 Flak Div (disliked by KAMMLER)
HEMMERS	Lt	Ic Div zV (formerly Ic 5 Flak Div)

GIERSBERG	Lt	OC coy of 1191 Nachr Abt

Last Stand

PWs mentioned a planned last stand of SS in LEUBACH Tunnel. They overheard phone conversation on this subject, LOIBACH (or LEUBACH, not LAIBACH) were mentioned. The LEUBACH Tunnel seems to be connected with many salt mines. PWs think it may be a vast underground city. Great food, ammo and other stores were brought there. More and more supplies are being sent there by SS. One PW overheard that KAMMLER's wife had been sent there. Until end of 44, CT workers were employed in construction work. They were replaced by SS Strafbattalions. All SS from AK zV and their clique intend to fight there to the last. The remaining V-2 Schiesszüge may be moved there together with A-Stoff reservoirs.

One PW saw a teletype message, Jan 45, saying that an ammo factory is already in production in the tunnel. He thinks the tunnel is somewhere in the SALZKAMMERGUT-TIROL.

HDP and Rheinboote

On or about Dec 44, Art Abt 705 and 709, one in Luxembourg and one in Holland, became subordinated to KAMMLER. Both bns turned in their 10.5 cm hows and were issued new secret weapons, HDP (Hochdruckpompe, code name for a 15 cm rocket weapon, and "Rheinboot" (a 21 cm rocket weapon).

The shells were supposedly launched from a tube like rockets as far as PW understood from teletype messages and phone talks. The crews of both bns had been trained. PWs remember the supposed range of the 'Rheinboot" to be 120 km. PWs think that KAMMLER was the guiding spirit, a diletante in secret weapons, because they recall definitely that KAMMLER boasted on New Years Eve (44/45) that both secret weapons had been used against orders from his superiors, 'auf meine eigene Verantwortung". In any case, in 3 weeks the bns got back their 105 cm hows, ceased to be subordinate to KAMMLER.

Special Military Court

A special military court belonged to Div zV and AK zV.

Military Installations

6. Führer HQ Tunnels

PW is familiar with the construction of a Führer HQ at WÜSTEGIERSDORF. He assumes that tunnels at BERCHTESGADEN, based on the same specifications issued by Gen Bauleiter Obst v BELLOW do not differ from those at WÜSTEGIERSDORF. Sketches are according to PW's memory of the master plan. The tunnels have been constructed along RR GLATZ-WALDENBURG NE of WUSTEGIERSDORF. They were to be completed for use March-July 45. Labor is done by OT, but principally by inmates from a S Hungarian concentration camp who receive brutal treatment at the hands of SS guards.

Construction

Above the surface are 3 bunkers, 6 stories high, with 7 m thick roofs and 5 m thick walls. A defense tower is at each corner. Below the surface are passageways containing offices, message centers, radio equipment, and machinery, all capable of operating for three days without contact with the surface. Underground halls are 6 m wide, 40 m below the surface. Entrance shafts are 2.20 m wide of reinforced concrete. A wall, 3.50 m thick protects the mouth of the tunnel. The roof covering the shaft is 5 m thick and increases to 7 m as the tunnel goes beneath a cliff. A stairway then leads to a lower level. Side entrances are closed by metal doors 2.07 x .95 m, (thickness unknown).

ENTRANCE STRUCTURE

The defense towers contain gun positions mounting SMGs or 2 cm Flak. Doors are of metal 2.07 x .95 m (same as above). Passages in the defense works are 3.50 x 2.20.

8. Storage of Documents

PW, secretary of Gen HEILMANN, carried secret documents from the Gen to CG der Ausb u Ers Truppen der Fallsch Armee (Genlt CONRAD), HERMANN GÖRING Kaserne, BERLIN-REINICKENDORF. Beneath the bldgs are elaborate air raid shelters with special safes for documents. Officers were still in same location and operating normally, 1-2 March.

PW states that the Archives for journals of Armies is located in BERLIN-POTSDAM.

One of the bldgs of SALAMANDER LAGER, located at 29 Linkstr, BERLIN W 9, was taken over by an SS office (PW saw many trucks unloading documents and equipment to be brought into the bldg) 3-11 March. Only 2 bldgs of the SALAMANDER LAGER complex were damaged by air raids, although almost all other houses on Linkstr have been hit.

(Source: Gren Adrjan STRUZYK Pole 986 Gren Ers Bn and one other captured 27 March vic NASSAU)

Secret Plans, WIESBADEN

SS Wirtschafts Verwaltungshauptamt, BERLIN has 3 Bauinspektionen (in BERLIN, WIESBADEN, and MUNICH). A fourth was formerly at KRAKOW. Plans in the BERLIN department were destroyed in an air raid, 1943. Since no duplicates existed, the plans were redrawn in WIESBADEN. Thus plans of Bauinspektion WEST as well as Bauinspektion NORD were at WIESBADEN. They were packed in 4 large wooden boxes, 20 July 44 and stored in EICHBERG (GSGS 4416/T2/2360), in the cellar of a private home nr NW gate of insane asylum. The house was occupied, summer 1944, by Sturmbannführer RIETL. PW is certain that plans are still there (up to 28 March 45) since SS guards fled 24 March.

PW thinks documents contain plans of SS Sonderkdo in charge of underground installations in the HARZ.

Personalities:

RIETL	Sturmbannführer	OC Bauinspektion WEST
MENZ	Sturmbannführer	Deputy OC
PAETOW	O/Sturmbannführer	Finance officer
CAMMLER	Gruppenführer	OC SS Wirtschafts Verwaltungs Hauptamt
OLDENBOUIS	Hauptsturmführer	OC Sonderkdo for secret SS construction work, former mayor of LÖRACH, holder of golden party badge

9. Personalities

Höherer SS-und Polizeiführer WEST, DÜSSELDORF

SS Obergruppenführer und Gen d Waffen SS is Höherer SS-und Polizeiführer WEST. He is appr 6 feet tall, thick set, very erect with a soldierly bearing, energetic, and pedantic. He is from Westphalia or the Rhineland. His offices are in DÜSSELDORF.

SS Obersturmbannführer Dr OSTERMAIER is Leitender Arzt beim Höheren SS-und Polizeiführer WEST. He is competent and good humored.

B. Garages for LKWs, PKWs, tractors, motorcycles, etc (no tks)
C. Stables and sheds for carts
D. Storage for Arty pieces. PW estimates there were appr 60-70 (12 cm and 15 cm). The bldg is painted green.
E. Warehouse and ammo storage
F. Storage for small Arty pieces, Inf hows, and 2 cm Flak
G. Lecture halls (3 story green bldgs, appr 50 x 30 m)
K. Storage of clothing and supplies
S. Barracks

The roads in the camp are camouflaged with nets and green paint. There are some Flak positions in the nearby woods (exact position not known).

LANDSBERG Airport

LANDSBERG Airport, although bombed, was still in operation 20 Jan 45. PW saw 8-10 planes which, he was told, were Turbinenjäger. All bldgs and hangars are camouflaged with nets.

(Source: Gren Alfons MARCIUKOWSKI Pole 3 Tp 555 Mtz Arty Bn)

19. Industrial Installations

RINNBACH

PW, unintelligent, saw construction of underground installations in a former chalk mine, at GSGS 4416/X8/536298, vic RINNBACH. PW's sister who lives nr the site claimed to know that the installation was to house an important "war factory", and th appr 13,000 workers, mostly Italian and Belgian civilians, were employed in two 12 hr shifts. Construction was begun in March 44 and HITLER was reported to have visited the site in June at which time he expressed dissatisfaction at the slow rate at which the work was progressing.

The entrance to the mine, according to PW, is easy to recognize from the air because it shows up plainly against the whit chalk of the mountain-side. Appr 30 green, one-story, wooden barracks with black tar-paper roofs are nearby. There are also many narrow gauge tracks for dump-carts which take soil from the excavation.

(Source: O/Gefr Josef POINTNER 189 Kraftfahr Coy 89 Inf Div captured 5 March)

New Locations, STEYR Works

While home on furlough (Feb 45) PW was told by friends that STEYR works had moved to new locations. He saw the sites from window of the train on which he was travelling.

The new factory is underground in the woods at GSGS 4416/X10 660855, S of the RR line. PW saw a tunnel running into the hill at this point. It is said to be appr 2 km long and running parallel to the RR tracks. A RR spur branching off the main line ran into the tunnel.

Construction on the underground factory was begun in Autumn 44 and was completed 15 Jan 45. Ball bearing and aircraft engine are produced. The new location was not bombed as late as 5 Feb.

Underground Factory, LAMBACH

(Supplementing PW INTELLIGENCE BULLETIN 2/44 Item 4)

PW who was in LAMBACH as late as 21 Jan 45 reports a factory, partly underground, in the woods between ROITHAM (GSGS 4416/X8/5354) and STADL PAURA (GSGS 4416/X8/5660). Construction of tunnels was begun as early as 1941, and the main rd ROITHAM-STADL PAURA was closed to all traffic in 1942. Traffic was rerouted via a rd E of the single track LAMBACH-GMUNDEN RR.

PW thinks that the factory is a GAF project because all military personnel in the area wore GAF, SS, or SA uniforms. SA seems to be in charge of guarding the installation. Men and women from the surroundings were employed in the factory in 1941 and 1942 when Arty ammo was manufactured and stored in the area. At that time barracks construction and excavation work was in progress.

Since 1942 local labor is employed only in that part of the installation which serves as an ammo depot, while Russian PWs worked in a section which was closed to all civilian workers. The Russians (men and women) live in the restricted area and are completely cut off from communications with the outside. Nothing was known regarding the type of work performed in the restricted section, even to the workers in the adjoining ammo storage.

Large box-car type trucks operated and serviced by GAF personnel are stationed at LAMBACH. Large, heavy wooden boxes are hauled from LAMBACH RR station into the closed off area by the trucks which also serve for transportation, particularly to a special RR station inside the area. A spur from LAMBACH RR station runs along the TRAUN river into the restricted section. Only box cars were seen entering and leaving.

(Source: Gefr Ernst LÖBERBAUER 11 Pz Gren Regt captured 25 March ASBACH)

Power Plant, ZELL/a See
(Supplementing PW INTELLIGENCE BULLETIN 2/44 Item 4)

A power plant has been under construction in the KAPRUN valley (SW of ZELL/a See) since 1938. A dam was being constructed in the upper part of the narrow valley. Workers' barracks are located along both sides of the valley rd wherever the terrain permits.

PW, who was at the location as late as 8 Feb, states that work was still in progress and material was being transported on the single track R^R from BRUCK. PW estimated that not more than 5,000 workers (mostly foreigners including PWs) were employed.

19. Industrial Installations (Continued)

Pressluft Factory, TRAUN SEE

30,000 prisoners, mostly from concentration camp MAUTHAUSEN, have been employed since Dec 43 in the construction of 4 tunnels into mountains S of the TRAUN SEE. Entrances are located on the NW slope of the HASLERGUPF mountain, between RIMBACH and ROTH. RR spurs lead to all four entrances. Tunnels are said to be 2 km long.

Work on the tunnels is supervised by SS who are also in charge of production which was begun in the underground installation appr Nov 44. The plant is reported to produce both compressed and liquid air. PW saw (Nov 44) appr 50 storage tanks, each having an estimated capacity of 50,000 liters, and some heavy machiners of unidentified type stored nr the tunnel entrances.

(Source: Fahrer Franz STUMMER Transportation Coy SPEER captured 21 March LINZ)

20. Defenses

Outer Defenses, Austro-Hungarian Frontier

As early as middle of Jan 45 Army personnel and civilians were employed in the construction of A-tk ditches along the Austrian-Hungarian-Yugoslav border, between the towns MOGERSDORF, ST MARTIN, MINIHOF-LIEBAU. The Volkssturm was activated and one rifle was issued for every five men. PW states that the population was more incensed against the Nazis than against the prospective invaders.

(Source: Gefr Gustav SCHAFFER 188 Füs Bn captured 24 March DINSLAKEN)

Preparations, vic BERCHTESGADEN

PW, who prior to his induction (Apr 44) was in charge of a childrens' evacuation camp reported, building activities vic BERCHTESGADEN which led to rumors among the population that the BERCHTESGADEN-FREILASSING district was planned as a vital point in the last-ditch defense.

The famous underground salt-mine (GSGS 4416/Y7/967071) was closed to the public and was reported to be converted into a huge storage place for all types of supplies, including ammo. New barracks were under construction on the airport. A second track was added to the BERCHTESGADEN-OBERSALZBERG-SCHELLENBERG-SALZBURG RR line. A tunnel (appr 400 m long) linking BERCHTESGADEN with the OBERSALZBERG depot runs between points 955059 and 958063. HITLER's RR train is known to be parked in this tunnel while HITLER is in the area. Many foreigners were employed on the RR constructions.

Large bunkers were blasted into the sides of the mountains, one at GSGS 4416/Y7/940060, facing the GMUND bridge, another across from the church at GSGS 4416/Y8/953061, a third in the NONN section. Others were planned.

David Irving. 1965. *The Mare's Nest.* Boston: Little, Brown. pp. 219–220

The remaining site, at Wizernes, caused some anxiety, as it was not obviously aligned on any city in Europe. One interpreter caused a high degree of alarm early in the year when he discovered that one facet of the workings was within half a degree of the accurate Great Circle bearing on New York. Whether the Germans planned this out of sheer mischief is not known; certainly Albert Speer denied after the war that there was ever any intention of firing their New York rockets from Wizernes; but it is a remarkable fact that the enormous bombproof doors and handling gear were all capable of handling a rocket about twice the height of the A 4, if necessary.

W. L. Heiberg. 26 October 1944. Franz Peter (Austrian), Germany–Inventions–Rockets. [NARA RG 38, Entry 98C, Box 3, Folder TSC #1001–1100]

1. Source states he is an Austrian refugee, 22 years of age, and that he arrived in Sweden in August, 1944, where he has been in an internment camp. He claims to have been a rocket specialist for the past eight(!) years, and to have worked at the Rheinmetall-Borsig plant in Sömmerda (NNE of Erfurt, Germany) from December, 1943, to May, 1944, after which he fled to Sweden. He worked in section WKbt of the Sömmerda plant, which, he states, is concerned with the manufacture of Germany's rocket weapons.

2. Source expresses a desire to go to Great Britain or U.S.A. to work on rockets for the United Nations, and has shown a 114-page (page 43 missing) manuscript in substantiation of his claim to intimate knowledge of Germany's "V" weapons. The manuscript has been photographed, and the negative is forwarded as enclosure (A). Enclosure (B) is a table of contents compiled in this office after summary study. [...]

5. Chapter thirteen discusses the principle of the multiple or tandem rocket. The rear or "booster" rocket (Schubrakete) has ten times the mass of the forward or "main" rocket (Hauptrakete). The booster carries the rocket part-way to the target, until the fuel is exhausted; then after launching the main rocket, it falls away. Source claims altitudes of 360 kilometers (223.7 miles) had been reached by such rockets before he fled from Germany in the summer of 1944, and that at this altitude the main rocket could be expected to have a range of 500 to 700 kilometers (310 to 434 miles). (Source did not divulge how altitude was determined.) Such rockets are not launched by catapult, but from a launching track and under their own power. The booster uses gasoline and liquid oxygen as fuel, while the main rocket uses liquid hydrogen and liquid oxygen. (Rockets of this type with a series of boosters were mentioned by Source in course of conversation. He claims an Atlantic rocket, to bomb New York, was calculated to require fifty-six minutes in flight.)

6. Chapter fourteen describes a revolutionary method of electric propulsion which Source claims as his own invention. He stated it was demonstrated at the Kaiser Wilhelm Institute at Potsdam in late spring or early summer, 1944, with good results. This method does away with large fuel tanks, affording more space for useful load, and is much more powerful than present fuels. Electric energy at ten million volts is generated within the rocket by the ionization of a salt solution according to what Source calls the "Kesselring" process, which is described with accompanying diagrams. (Source states this process was discovered by a German scientist in 1937.) This high voltage is discharged in the rocket's exhaust tube, causing a vapor or gas (unidentified) to explode violently,

giving a propulsive exhaust impulse of 1,000 kilograms per second per square centimeter, of 78,590 kilograms (ca. 78 tons) per second, with a ten centimeter (2 1/2") exhaust tube. (Source stated orally that discharges occurred twenty times per second.) Source claims this process could also be used in propelling units for all types of transportation.

[Franz Peter's claim to have been working on rockets since age 14 is not unreasonable. Wernher von Braun began experimenting with rockets at age 12, and many other German-speaking students became interested in rockets at young ages in the 1920s and 1930s. Moreover, with most fighting-age men sent to the front lines, it was not unusual to employ younger individuals in war-related work at home, including rocket development (p. 5313).

Rheinmetall-Borsig is known to have made major advances in developing and demonstrating multi-stage, relatively large solid propellant rockets. See p. 5663. They may well have been involved in other rocket-related work.

Numerous other reports also stated that there were large rocket development and testing programs in the greater Erfurt area.

Franz Peter appeared to be very knowledgeable about rockets, and he appeared to have been involved with actual German rocket development programs for a considerable period of time. He claimed that prior to his leaving in May 1944, the German program had:

- Launched a rocket to an altitude of 360 km. The A-4 (V-2) rocket had a maximum altitude of approximately 200 km if launched vertically. Thus if Peter's claim is true, it describes a more advanced rocket.

- Launched two-stage liquid propellant rockets. If that claim was true, the simplest explanation may be that an A-4 (V-2) or similar rocket had been used as the first stage, and a much smaller rocket had been mounted on top of that as a second stage. Several such rockets, dubbed the Bumper series, were tested in the United States after the war (p. 5314). Those may have been based on successful wartime German experiments, if Franz Peter's information was accurate.

- Launched a rocket that used liquid hydrogen as fuel, a major advance over known German rockets that used ethanol or other hydrocarbons as fuel. As a very new and experimental technology, that would be consistent with the possibility of first testing just a very small hydrogen-powered rocket, for example mounted on top of a much larger A-4 rocket.

- Experimented with ion rocket engines. While Peter's claims for the performance of ion rocket engines and his own contributions to them may have been overstated, German scientists such as Ernst Stuhlinger did invent ion rocket engines, conduct at least some experiments during the war, and ultimately fully develop them in the United States after the war.

The above document mentioned a film negative containing Franz Peter's 114-page manuscript. That film roll was still stored in a canister alongside this document in the NARA file box. Unfortunately, due to the passage of time, the film is fused together and crumbling, and appears to be unreadable, as shown on p. 5315.]

John A. O'Mara to Lowell P. Weicker. 14 June 1944. Headquarters, U.S. Strategic Air Forces in Europe, Office of the Director of Intelligence [AFHRA A5734 frames 1369–1370]. [See document photos on pp. 5317–5318.]

[...] Investigation quickly disclosed that there was a group of party technicians in the Wehrmacht experimenting with a very large conventional type of rocket with a total weight in the neighborhood of 68 tons. Another group of scientists in the GAF technical development section were working on a jet-propelled pilotless aircraft and both organizations were testing some of these weapons at Peenemünde, on the shores of the Baltic.

On the 17th of August 1943 construction on a number of strange sites located on the Cherbourg Peninsula and in the Calais area were discovered. Work on these sites progressed at a snail's pace. It took some little time before it was definitely established that these were the so-called secret weapon sites and were linked to the long range weapon experiments at Peenemünde. Ninety-six of them were constructed for the launching of pilotless aircraft and seven were for the launching of giant sized rockets. [...]

The reported explosions at Maidstone of giant conventional rockets turned out to be nothing but long range, eight inch, naval shells, so that as yet there is nothing upon which to assess the actual value of the projected 68 ton conventional rocket. [Not yet deployed in combat.]

Arnold Deeply Concerned with the German Developments of Robots, Rocket Torpedoes, and Jets—July 1944 [AFHRA 43811 electronic version pp. 962–963].

[...] Arnold was most concerned. "If this rocket procedure is allowed to be developed uninterrupted, there may come a time when these large 75 ton rockets land in England, in occupied France, or possibly if they are radio-controlled, in the United States. We must use everything in our power to prevent any such occurrences."

[The A-4 or V-2 rocket weighed 14 tons. Yet the highest levels of U.S. intelligence reported with great confidence that rockets weighing 68–75 tons were also under active development and experimentation through 1943 and 1944. What evidence did U.S. intelligence have? Note that an A-10 rocket by itself, with no A-4 upper stage or payload, would have weighed around 69 tons (p. 5800).]

MEMORANDUM:

TO : COL. L. P. WEICKER

In the face of continued reverses and diminishing manpower and materials during the Spring of 1943, it became very apparent that very drastic steps had to be taken if the German Government even hoped to stave off defeat. We are just now beginning to appreciate what some of those drastic steps were. One such step is the attempt to develop a substitute for planes and pilots and this was the story behind their much publicised (so-called) secret weapons.

In January 1943 General Galland, at that time in charge of GAF technical development acknowledged the declining strength of the Luftwaffe before a large audience of Military and high Party officials. He said the plans had been made for a new air force and promised greatly increased performance for new planes which would be ready for the Spring campaign. Production was increased slightly on improved models, but the performance of these new planes didn't begin to live up to the promises. Just when this became self evident high officials of the Wehrmacht and the GAF started talking of "Secret Weapons".

Investigation quickly disclosed that there was a group of party technicians in the Wehrmacht experimenting with a very large conventional type of rocket with a total weight in the neighborhood of 68 tons. Another group of scientists in the GAF technical development section were working on a jet-propelled pilotless aircraft and both organizations were testing some of these weapons at Peenemunde, on the shores of the Baltic.

00217645

On the 17th of August 1943 construction on a number of strange sites located on the Cherbourg Peninsula and in the Calais area were discovered. Work on these sites progressed at a snails pace. It took some little time before it was definitely established that these were the so-called secret weapon sites and were linked to the long range weapon experiments at Peenemunde. Ninety-six of them were constructed for the launching of pilotless aircraft and seven were for the launching of giant sized rockets.

By the constant attacking of these sites chiefly by planes under the control of USSTAF, practically all of the original pilotless aircraft or ski sites and two of the large rocket or large sites have been neutralized. However, recently the GAF has hastily erected 66 modified pilotless aircraft sites of which forty-two are in the Calais area, four in the Calvados and the rest in the Cherbourg area. With bombing having practically neutralized the old ski sites and the Allied invasion having interfered with all but the forty-two modified sites in the Calais area, the question is just what is the potential danger from these sites still available and workable by the GAF.

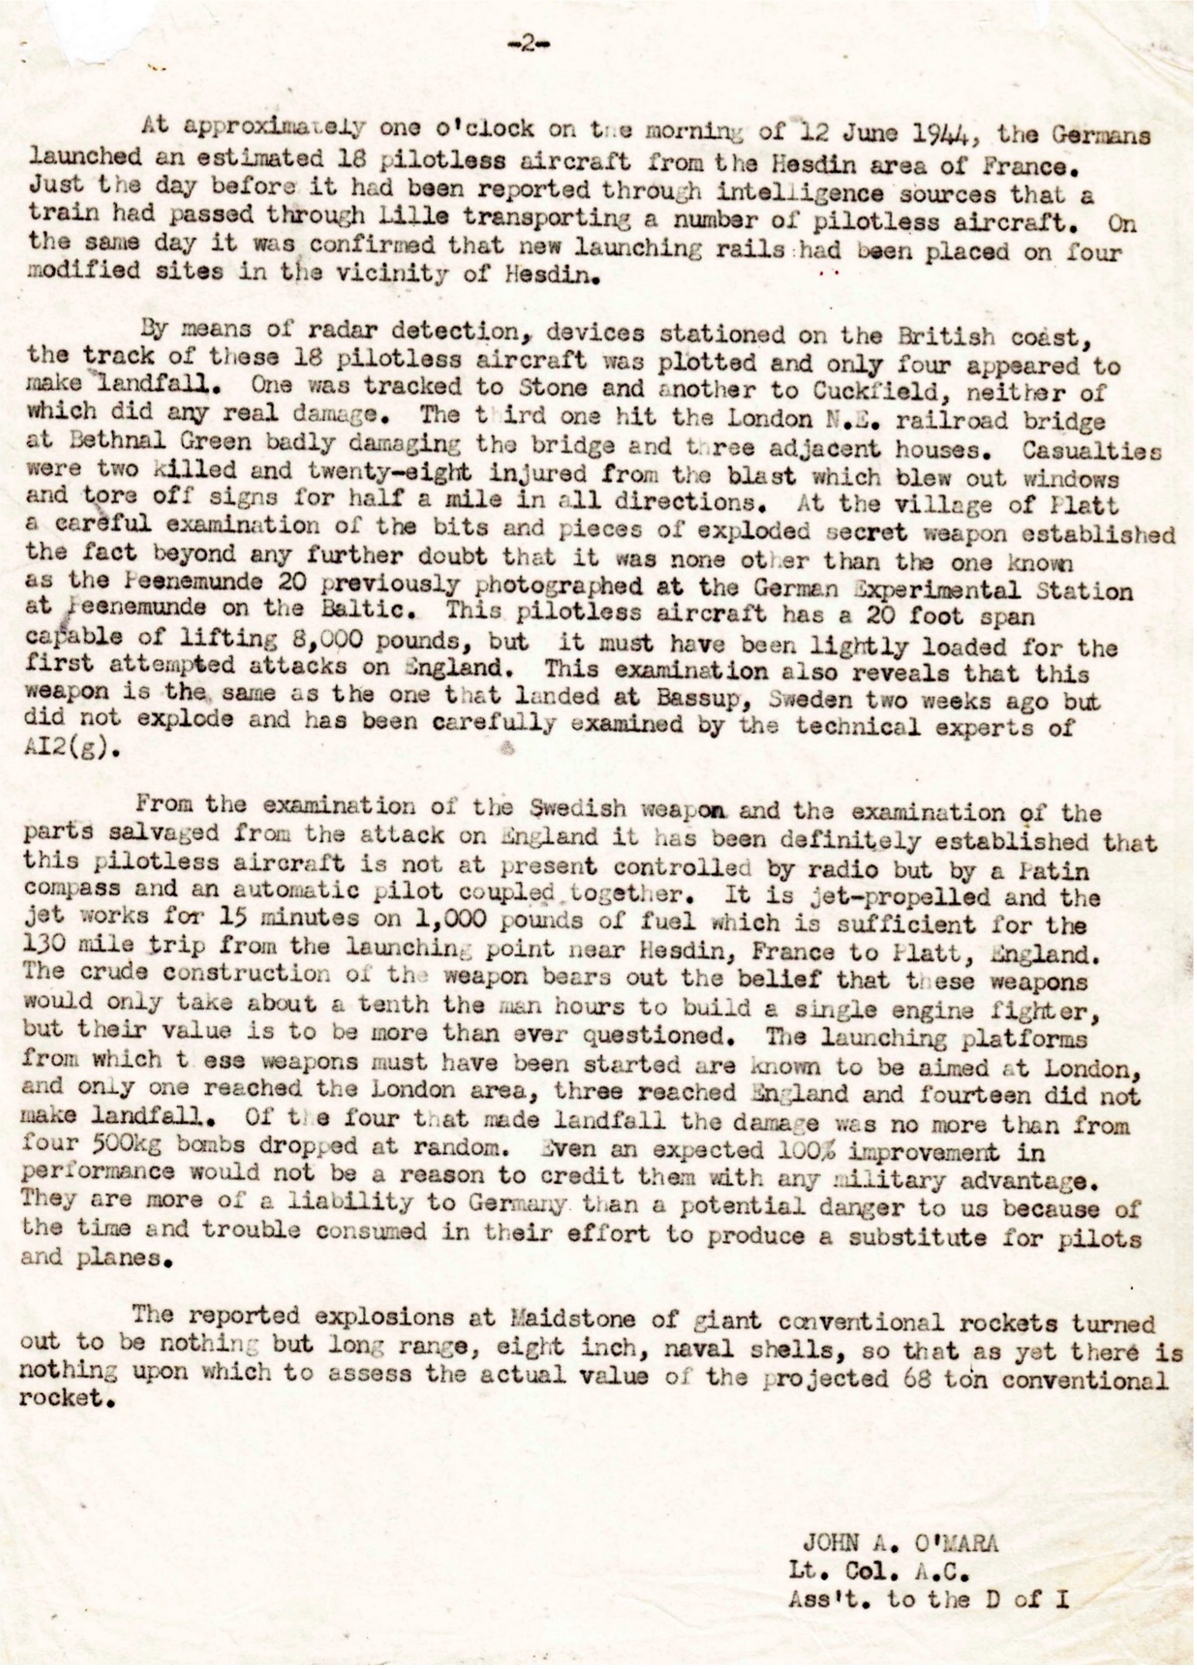
Figure E.68: John A. O'Mara to Lowell P. Weicker. 14 June 1944. Headquarters, U.S. Strategic Air Forces in Europe, Office of the Director of Intelligence [AFHRA folder 519.6522-4; AFHRA A5734 frame 1369].

AFHRA folder 519.6522-4



-2-

At approximately one o'clock on the morning of 12 June 1944, the Germans launched an estimated 18 pilotless aircraft from the Hesdin area of France. Just the day before it had been reported through intelligence sources that a train had passed through Lille transporting a number of pilotless aircraft. On the same day it was confirmed that new launching rails had been placed on four modified sites in the vicinity of Hesdin.

By means of radar detection, devices stationed on the British coast, the track of these 18 pilotless aircraft was plotted and only four appeared to make landfall. One was tracked to Stone and another to Cuckfield, neither of which did any real damage. The third one hit the London N.E. railroad bridge at Bethnal Green badly damaging the bridge and three adjacent houses. Casualties were two killed and twenty-eight injured from the blast which blew out windows and tore off signs for half a mile in all directions. At the village of Platt a careful examination of the bits and pieces of exploded secret weapon established the fact beyond any further doubt that it was none other than the one known as the Peenemunde 20 previously photographed at the German Experimental Station at Peenemunde on the Baltic. This pilotless aircraft has a 20 foot span capable of lifting 8,000 pounds, but it must have been lightly loaded for the first attempted attacks on England. This examination also reveals that this weapon is the same as the one that landed at Bassup, Sweden two weeks ago but did not explode and has been carefully examined by the technical experts of AI2(g).

From the examination of the Swedish weapon and the examination of the parts salvaged from the attack on England it has been definitely established that this pilotless aircraft is not at present controlled by radio but by a Patin compass and an automatic pilot coupled together. It is jet-propelled and the jet works for 15 minutes on 1,000 pounds of fuel which is sufficient for the 130 mile trip from the launching point near Hesdin, France to Platt, England. The crude construction of the weapon bears out the belief that these weapons would only take about a tenth the man hours to build a single engine fighter, but their value is to be more than ever questioned. The launching platforms from which these weapons must have been started are known to be aimed at London, and only one reached the London area, three reached England and fourteen did not make landfall. Of the four that made landfall the damage was no more than from four 500kg bombs dropped at random. Even an expected 100% improvement in performance would not be a reason to credit them with any military advantage. They are more of a liability to Germany than a potential danger to us because of the time and trouble consumed in their effort to produce a substitute for pilots and planes.

The reported explosions at Maidstone of giant conventional rockets turned out to be nothing but long range, eight inch, naval shells, so that as yet there is nothing upon which to assess the actual value of the projected 68 ton conventional rocket.

Figure E.69: John A. O'Mara to Lowell P. Weicker. 14 June 1944. Headquarters, U.S. Strategic Air Forces in Europe, Office of the Director of Intelligence [AFHRA folder 519.6522-4; AFHRA A5734 frame 1370].

Henry Arnold to Carl Spaatz. 22 July 1944. Outgoing Classified Message WAR 69061. [Franklin Delano Roosevelt Library, Hyde Park, New York. Map Room Files, Box 49. Folder Rocket Bombs 1944]

I agree with you that everything possible must be done in order to determine ways and means of preventing the large German rockets from ever reaching their destination or causing damage to US. This in reply to your 65292. Doctor Bowles and his assistants are working on this problem and have been working on it for some time, particularly from the radio countermeasures viewpoint. Doctor Fraenckel has brought back from England information of great value in our countermeasure work and has already met with McClelland and others to formulate a specific program including proper search facilities and jamming equipment. We will keep you posted on techniques and on schedules of equipment which we propose to supply. As soon as suitable jamming materials are developed they will be sent to you posthaste. Doctor Fraenckel will return to England within a very short time and be prepared to give you such aid and advice as he can. He should be able to leave here not later than July 30th. If you have any other ideas as to how we can help you let us know.

War Cabinet. "Crossbow" Committee. "Big Ben" Sub-Committee. 17 August 1944 [AFHRA A1263 frame 1404]

Despite the reported lack of supporting evidence it was generally felt that the Swedish rocket [Peenemünde A-4 rocket that crashed in Sweden] had been designed to take more than one weight of warhead. It was pointed out that, within the suggested specification, an α of .62 would carry a charge of about 2 tons to a range of approximately 120 miles.

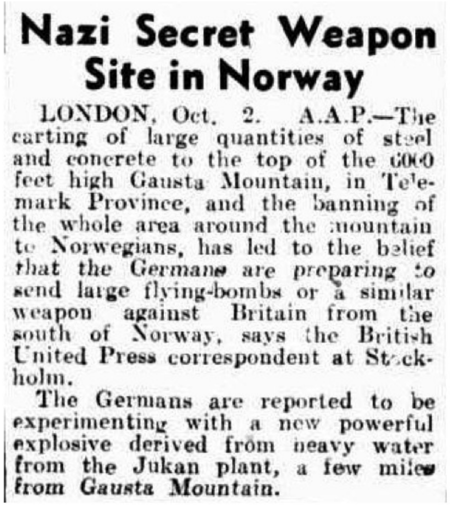
H. L. Morrow. 10 November 1944. Intelligence Information from Stockholm. [AFHRA C5095 frames 1496–1498]

The following observations constitute a resume of information received via the Italian "I" Office from the Air Attaché with the Italian Legation, Stockholm, together with a summary of his conversation with a Swedish Engineer, JOHANSON, representative of the Swedish Air Force in Italy, who returned to Sweden from MILAN at the end of September last. [...]

"V-1" is to be perfected in order to increase its range and size. When that is accomplished it will be known as "V-2", the chief difference being that "V-2" is to have a destructive power equal to 50 tons of explosive. In this connection important experiments are being made on the heights of Mount Gausta (1,900 m) near RJUKAN, Norway, where there is a probable launching site. Experiment on "V-2" has not so far evolved final adjustment of direction control and damage power (eg: its strike causes such excessive penetration that the explosive effect is less than "V-1"). Therefore the major German effort is now directed towards the development of "V-3"—a large chemical incendiary bomb (deflagrazione). This latter is constructed in two parts—actually two bombs—each loaded with different chemical compounds which ignite with devastating effect upon contact with air. [...]

[This was apparently a delayed report of intelligence from summer 1944, after the V-1 cruise missile had been publicly named and utilized but before the V-2 (A-4) rocket had been officially named and used in combat. That timing explains the confusion over whether the V-2 and V-3 were upgraded versions of the V-1 cruise missile or entirely different weapons. The upgraded warheads sound like Zippermayr-type fuel-air explosives or something else similar. The report of secretive German work on Mount Gausta in Norway may be the most interesting part of this report. The report also provided intelligence details about new jets, submarines, and tanks that appear relatively accurate in hindsight, so this V-2/V-3/Gausta report should also be taken quite seriously.]

Newcastle Morning Herald and Miners' Advocate
3 October 1944 p. 1



Nazi Secret Weapon Site in Norway

LONDON, Oct. 2. A.A.P.—The carting of large quantities of steel and concrete to the top of the 6000 feet high Gausta Mountain, in Telemark Province, and the banning of the whole area around the mountain to Norwegians, has led to the belief that the Germans are preparing to send large flying-bombs or a similar weapon against Britain from the south of Norway, says the British United Press correspondent at Stockholm.

The Germans are reported to be experimenting with a new powerful explosive derived from heavy water from the Jukan plant, a few miles from Gausta Mountain.

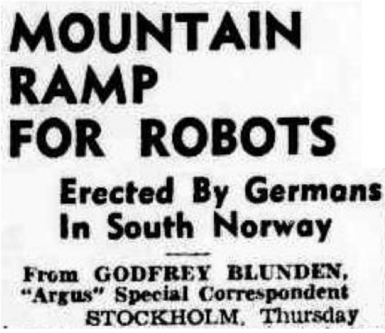
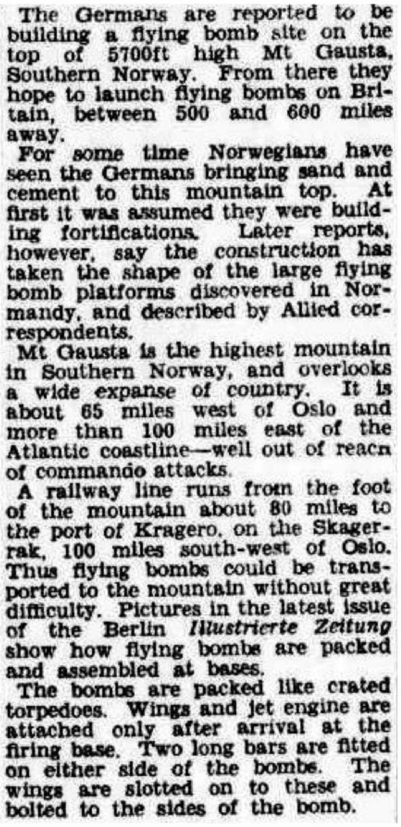
p. 16



MOUNTAIN RAMP FOR ROBOTS

Erected By Germans In South Norway

From GODFREY BLUNDEN, "Argus" Special Correspondent
STOCKHOLM, Thursday



The Germans are reported to be building a flying bomb site on the top of 5700ft high Mt Gausta, Southern Norway. From there they hope to launch flying bombs on Britain, between 500 and 600 miles away.

For some time Norwegians have seen the Germans bringing sand and cement to this mountain top. At first it was assumed they were building fortifications. Later reports, however, say the construction has taken the shape of the large flying bomb platforms discovered in Normandy, and described by Allied correspondents.

Mt Gausta is the highest mountain in Southern Norway, and overlooks a wide expanse of country. It is about 65 miles west of Oslo and more than 100 miles east of the Atlantic coastline—well out of reach of commando attacks.

A railway line runs from the foot of the mountain about 80 miles to the port of Kragero, on the Skagerrak, 100 miles south-west of Oslo. Thus flying bombs could be transported to the mountain without great difficulty. Pictures in the latest issue of the Berlin *Illustrierte Zeitung* show how flying bombs are packed and assembled at bases.

The bombs are packed like crated torpedoes. Wings and jet engine are attached only after arrival at the firing base. Two long bars are fitted on either side of the bombs. The wings are slotted on to these and bolted to the sides of the bomb.

Gausta mountain near Vemork in Norway

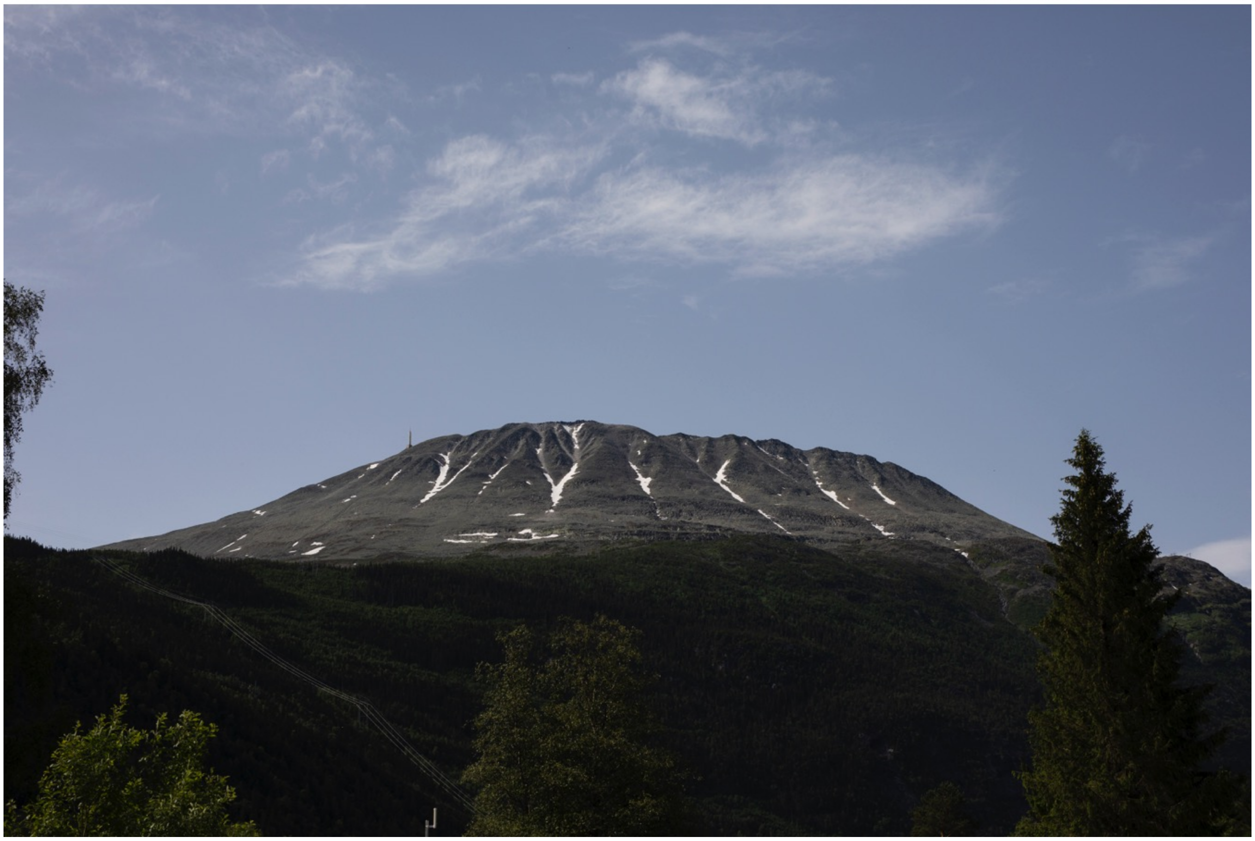


Figure E.70: Gausta mountain in Norway was the site of a very secretive German installation that may have been designed to launch and/or control long-range rockets.

Harry Vosser. Germans Are Still Striving to Perfect New V Weapons. *New York Times*. 22 October 1944, p. E5.

[...] If Hitler can get the necessary breathing space by holding the invading Allied armies on the borders of the Reich for from three to six months more, he may enable the scientists to complete their work.

V-2—a rocket projectile—was reported by the Germans to be ready some time ago. This was confirmed by neutral sources which said that rockets had landed in Sweden and Poland from the firing point at Peenemünde. [...]

Hitler is said to have stopped the production of that type of rocket and to have ordered scientists to concentrate on the production of bigger and more powerful ones. At least four of these latest experimental rockets are reported to have landed in Sweden and many more have crashed into the Baltic sea off Sweden's southeast coast. [...]

V-3 is reported to be the atom bomb. Dr. Goebbels has until now kept quiet regarding this one, but it is said that German scientists credit the weapon with having enormous possibilities.

Neutral sources describe the atom bomb as resembling an airplane in shape, with complicated machinery for steering and propelling the bomb to its target. The rest of the space is filled with explosives and fuel, the amount of explosives being governed by the amount of fuel necessary to carry to the bomb to its selected target.

An electric shock from a small instrument set to operate at a given time detonates explosive and atom simultaneously. The expansion caused by a normal explosive substance, such as dynamite when it becomes a gas, is increased by the force of the disintegrating atoms.

[...I]t is significant that two or three sources have reported the existence of the weapon. It is interesting too to note that a report from the Berlin correspondent of a Swedish newspaper describes V-3 as "the America Bomber and the biggest and best of all Hitler's secret weapons." The correspondent said that successful experiments had been completed in Austria and that the weapon would carry two members of Himmler's recently founded SS air force. He finished his article with the words "America will soon known what war is."

[...] There is no possible doubt that the Germans are straining every nerve to complete it and put it to use before the forthcoming onslaught by the Allied armies.

[This remarkably early article, based on several independent sources, publicly reported important details that were later confirmed by a number of additional sources:

- Germany was building a rocket that was "bigger and more powerful" than the V-2, "resembling an airplane in shape" (with wings), that "would carry two members of Himmler's recently founded SS air force" from its launch point in Europe to America (see all the other documents in Sections E.2 and E.3, but especially pp. 5365–5388 and 5600–5603).
- The rocket would deliver an atomic bomb that simultaneously used high-voltage electricity (a high-voltage fusion neutron initiator) and the detonation of surrounding conventional explosives (implosion) to release large amounts of energy from fission fuel ("the force of the disintegrating atoms"). See pp. 4485–4501 and Sections D.8 and D.15.5.

Where are the official reports on large rockets that were recovered outside Germany during the war, as well as any that were discovered after the war? Where are the reports on the "successful experiments" that "had been completed in Austria"? Can those be located and declassified?]

Aftontidningen **(Stockholm), 2 December 1944, p. 7.**

Raketbomben för New York färdig i år?	Rocket bomb for New York finished this year?
Minister Speer meddelade vid ett sammanträde med rustningsrådet för den tyska industrin att Wehrmachts överkommando ansåg de resultat som åstadkommits med V-2 tillfredsställande. Ytterligare förbättringar håller på att vidtagas. V-3, som är avsedd för beskjutning av New York, är så pass färdig att man har beräknat de första provskjutningarna till slutet av denna månad.	Minister Speer announced at a meeting of the German Industry Armaments Council that the Wehrmacht High Command considered the results achieved with V-2 satisfactory. Further improvements are being made. The V-3, which is intended for bombing of New York, is so complete that the first test launches are estimated by the end of this month.

V-3 Ready to Hit New York This Month, German Says. *New York Times*, 3 December 1944.

A Stockholm dispatch quoted the German labor chief, Albert Speer, yesterday as saying that Germany's V-3 weapon would be ready for firing against New York by the end of December. No intimation of its nature was given.

Deputy Chief Police Inspector Arthur W. Wallander, chief of staff of the city protective forces, said here yesterday: "Our services are ready." Mayor La Guardia warned on Nov. 12 that, "although there is no reason for alarm, we must be ready."

[In the Nuremberg trials, Albert Speer essentially denied the existence of any secret weapons, yet in this news report he publicly announced that they were being prepared for use. Many different weapon systems were competing for the title of V-3, the next German secret weapon to be publicly announced and demonstrated. Other than being able to hit New York, it is not clear if this particular "V-3" was a submarine-launched V-1 cruise missile, a submarine-launched V-2 or A-4 rocket, a European-launched A-9/A-10 intercontinental rocket, or something else.

Note that the *New York Times* misquoted the Stockholm newspaper. According to the Stockholm paper, Speer said that by the end of December 1944, the V-3 missile would be ready for test flights, not ready for an attack against New York then.]

Preparing the American Public for a V-3 Attack—Dec. 1944 [AFHRA 43811 electronic version p. 972]

At a CCS meeting in Washington, Dec 8, 1944, the CCS discussed "without much interest" a Presidential directive which would take action to meet a V-3 threat—intercontinental missile attack against the United States. Kuter reported to Arnold and Giles that the JCS was directing commanders to take preliminary actions and to prepare plans. "From their tone I feel they will accept or surely give serious consideration to a study pointing toward a Presidential announcement of the possibility of attack, the victory the enemy would achieve if we (don't?) take preparatory action and our decision to rely on the ability of the American public to take it." Kuter said he discussed the matter with Hull (Army Deputy Chief of Staff) and he directed Loutzenheiser, with McKee's assistance, to prepare a necessary study.

[See also related documents on pp. 4702–4703 and 5618–5660.]

Jürgen Michels. 1997. *Peenemünde und seine Erben in Ost und West: Entwicklung und Weg deutscher Geheimwaffen.* Bonn: Bernard & Graefe, p. 71.

Unter der Bezeichnung Aggregat 8 liefen eine ganze Reihe zum Teil stark voneinander abweichende Entwürfe. Die erste Studie entsprach in der Größe dem Aggregat 5, sollte aber durch Salbei und Visol (auch als Gasöl bezeichnet) angetrieben werden. Ende 1941 entstand eine sog. Hochdruck-Rakete, die in der Größe dem Aggregat 4 entsprechen sollte. Mit 8330 kg Salpetersäure und 1670 kg Gasöl sollten ca. 50,000 kp Schub erreicht werden. Diese Rakete sollte einen Sprengkopf von 2000 kg über 300 km tragen. Noch größer war ein weiterer Entwurf, der 14.295 kg Salpetersäure und 2860 kg Gasöl vorsah. Obwohl ein niedrigerer Schub von 35.000 kp geplant war, erhoffte man aufgrund einer langen Brenndauer von ca. 100 Sekunden eine Höchstgeschwindigkeit von 7380 km/hr zu erreichen und eine Nutzlast von 2500 kg etwa 450 km weit zu verschießen. Das Startgewicht war auf 22.370 kg ausgelegt.

Keine dieser Studien kam letztendlich über Windkanalversuche hinaus.

A whole series of designs, some of which differed greatly from one another, ran under the name Aggregat 8. The first study corresponded in size to Aggregat 5, but was to be powered by Salbei and Visol (also known as gas oil). At the end of 1941, a so-called high-pressure rocket was developed, which was to correspond in size to Aggregat 4. With 8330 kg of nitric acid and 1670 kg of gas oil, a thrust of approximately 50 tons was to be achieved. This rocket was to carry a warhead of 2000 kg over 300 km. Even larger was another design, which envisaged 14,295 kg of nitric acid and 2860 kg of gas oil. Although a lower thrust of 35 tons was planned, it was hoped that a maximum speed of 7380 km/hr could be achieved due to a long burn time of approximately 100 seconds and a payload of 2500 kg could be fired over a distance of around 450 km. The launch weight was intended to be 22,370 kg.

None of these studies ultimately got beyond wind tunnel tests.

[Among the several different proposed A-8 designs were some that were extended versions of the A-4 with higher thrust, for longer ranges and/or higher payload capacities. According to official postwar history books, such extended A-4 rockets were never actually built. However, as shown by documents throughout this section, there is significant evidence that at least some extended rockets were indeed built and possibly tested. These wartime prototypes also served as the basis of many postwar U.S., Soviet, and French rockets (Section E.7.2).]

Gerhard Reisig. 1997. *Raketenforschung in Deutschland: Wie die Menschen das all eroberten.* Münster: Edition Lenser. pp. 707–708.

In seinem Memorandum "Entwicklungsgrundsätze" vom November 1941 hatte W. Dornberger postuliert, daß die "A4"-Rakete nur eine temporäre Zwischenlösung sein sollte. Die tatsächliche militärische Forderung bestehe auf einer Fernrakete von 450 km Reichweite (Dornberger, 1941). Die entsprechende Raketentype erhielt die Bezeichnung "A8". [...]

In his memorandum "Development Principles" of November 1941, W. Dornberger postulated that the "A-4" rocket should only be a temporary interim solution. The actual military requirement was for a long-range missile with a range of 450 km (Dornberger, 1941). The corresponding rocket type was given the designation "A-8." [...]

Das “A8”-Projekt erforderte also eine grundlegende neue Systemkonfiguration, die analytisch eingehend untersucht wurde (Hellebrand, 1942). Meissner (1941) diskutierte 16 verschiedene Konfigurationen einer “A8”-Rakete, um einen optimalen Ausgleich der verschiedenen Parametergrößen der Rakete zu bestimmen. Bei diesen Entwürfen sollte die aerodynamische Form der “A4”-Rakete möglichst erhalten bleiben.

Die Grundlage der “A8”-Konfiguration bildet ein neues Triebwerk von 30 to (294 kN) Schub. Werner Thiel hatte die Entwicklung eines solchen Triebwerks bereits 1941 begonnen (Thiel, 1941). Die Treibstoffbasis für den 30-to-Motor ist die Kombination von Gasöl mit *Salbei*. Das Gasöl kann gegen ein 50-prozentiges Gemisch von Benzol und Benzin ausgetauscht werden. Dieser Motor ist eine Hochdrucktype mit einem Brennkammerdruck von 40 atü (41 Bar). Mit dem 30-to-Triebwerk wird eine Brennschlußgeschwindigkeit von über 2,000 m/sek bei der Machzahl 6,8 erreicht. Bei diesen hohen Machzahlen wird die Körperlage der Rakete instabil, d.h. der Luftangriffspunkt aller Luftkräfte auf die Rakete rückt vor deren Schwerpunkt. Eine gewisse Verbesserung der Stabilität wird durch Verlängerung der Zelle auf L = 13.5 Kaliber erreicht.[7] [...]

Die “A8”-Rakete wäre ein fortschrittliches, wegweisendes Projekt gewesen. Sie blieb nur ein “Papierprojekt”.

Tabelle XI.2 Dimensionen des “A8” Modells

Länge: 13.5 Kaliber
Kaliber: 1.651 mm
Leergewicht: 22,8 to/224 kN
Brennschluß-Machzahl: 6,8

The “A-8” project thus required a fundamentally new system configuration, which was analyzed in detail (Hellebrand, 1942). Meissner (1941) discussed 16 different configurations of an “A-8” rocket in order to determine an optimal balance of the various parameters of the rocket. In these designs, the aerodynamic shape of the “A-4” rocket was to be retained as far as possible.

The basis of the “A-8” configuration was a new engine with a thrust of 30 tons (294 kN). Werner Thiel had already begun the development of such an engine in 1941 (Thiel, 1941). The fuel basis for the 30-ton engine is a combination of gas oil and *Salbei*. The gas oil can be replaced with a 50 percent mixture of benzene and gasoline. This engine is a high-pressure type with a combustion chamber pressure of 40 atmospheres (41 bars). With the 30-ton engine, an engine cutoff velocity of over 2,000 m/sec, Mach number of 6.8, is achieved. At these high Mach numbers, the rocket becomes aerodynamically unstable, i.e. the center of pressure of all aerodynamic forces on the rocket moves in front of its center of gravity. A certain improvement in stability is achieved by lengthening the airframe to L = 13.5 diameters.[7] [...]

The “A-8” missile would have been an advanced, pioneering project. It remained only a “paper project.”

Table XI.2 Dimensions of the “A-8” model

Length: 13.5 diameters
Diameter: 1.651 m
Weight without payload: 22.8 tons/224 kN
Engine cutoff Mach number: 6.8

D'ETAT

SECSTATE
WASHINGTON

WATCH. Repeated London and Algiers.

Following obtained by Austrian contact who has proved reliable but his source untested by us.

Germans already manufactured 12,000 rocket projectiles 10 to 12 tons total weight containing 3 plus tons explosive charge consisting of propane in some types and propylene in other types. Projectiles are 12 to 15 meters long. Twenty meter model abandoned because always exploded in air. Transport is by special RR cars with 10 axles. Range 230 to 330 km. Hits ground at angle of 48 degrees. Launched by apparatus powered with steam. Explosive charge in nose is followed by chamber capable receiving radio stimulus then cell containing rocket fuel composed of butane acetaldehyde and **source** understands also nitric or perhaps nitrous acid. Next chamber is for combustion where fuel burns in presence of nitric or perhaps nitrous acid. Part of escape gases operates turbine which another source says is to compress air required for combustion of fuel. Outer case is double with carbonic acid between for cooling. Firing locations are near Calais, St. Omer (these two towns have 17 batteries) and in Holland Belgium Denmark. (From 110. View range last location not comprehensible). Date for beginning their use postponed ~~fxx~~ from Xmas to beginning Feb. 1944. Suggests consulting Fritz von Opel who we understand is in USA. Manufacturers in Austria and vicinity include Raxwerke at Vinzendorf am Schneeberg also at Ebensee and Alt-Oetting. Also in region Berchtesgaden and parts are made in Heinkel works Schwekat and another Schwekat factory.

Some Germanx night fighters have rocket projectiles timed to explode at 1200 meters for use against Flying Fortresses.

Germans still make Schalltorpedoes shot from planes and directed by radio also torpedoes wound with point three mm wire.

Different and fairly reliable source reports plant of Lindes Eismaschinen AG at Hoellriegelskreutz who must be large producers of propane are filling shells or bombs for some secret weapon.

SECSTATE

WATCH. Repeated to Algiers.

Following from 821 following trip North. Dec. 9 to 12.

(Several paras BO.)

Friedrichshafen. 821 went particularly this area to investigate work there on secret weapon presumably preparation explosive filler for rocket. Claims following from inside source.

Following location secret installation: from Oberraderach follow good earth road 500 meters west along ridge here road turns north and south. North road mere camouflage and leads to fake camp. South road after 150 meters turns west for about 200 meters and reaches camp with 20 barracks in two north south rows. Immediately southeast this camp hidden in woods are laboratories and other installations consisting of 20 reinforced concrete bunkers about 30 meters square and fairly deep although not an underground plant. See our 1232. This camp is slightly east of Kluftern and half way on straight line from Markdorf to Friedrichshafen. Markdorf has 2 flak batteries in town. On lake shore 3 KP fog troops. Rumored that fog exercises have poisoned vegation along lake. Above camp has some 4,000 ex-concentration camp and penitentiary prisoners. Heavy military guard.

Rocket has charge of poison gas combined with compressed air which has terrific explosion. Steel cylinders manufactured near Strasbourg and then shipped to Friedrichshafen. Sources informant is doctor who largely engaged in attending lung cases among workers.

From 493 source. German technicians working in large underground development back of Fischbach on Bodensee. Entrance at Manzell and main establishment near Kluftern. Believed to have something to do with secret air weapon.

[The sites named above are in the Friedrichshafen area. For more on OSS agent "493," see p. 4176.]

R. R. Thun. 5th Army POW Cage (Air), Target Notes A/5. 4 November 1944. [AFHRA A5417 electronic p. 969–970]

5. Under-ground Factory in FRIEDRICHSHAFEN: In Jan/43 P/W visited the site of a large new under-ground factory being built by Dornier at FRIEDRICHSHAFEN. Factory lies between the lake and the road to IMMENSTAAD, on the NW edge of FRIEDRICHSHAFEN. It is covered by a storage yard for wood and other bulk materials, and there is a R.R. spur leading into the underground part. P/W could give no information as to the size of the underground unit, other than to say that it was about the same size as the large Mercedes Factory in STUTTGART. He heard from friends that V-2 was being made there, and that three R.R. cars were necessary to haul away a single V-2 bomb. P/W considered himself an Italian, having been born in BOLZANO, and was obviously trying to give reliable information.

[See document photos on pp. 5328–5329. See also p. 5392, although there the answers to postwar questioning may have been less than complete and accurate.

Wartime German railroad cars were most commonly around 8–10 meters long. A standard A-4 (V-2) rocket was 14 meters long with all parts from the nosecone to the fins attached. Thus a standard A-4 could have been carried by a single railroad car of somewhat greater than average length (or by a single car of average length, if partially disassembled), or at most by two average-length railroad cars with plenty of room to spare.

If the rockets produced by this underground factory at Friedrichshafen required three average-length railroad cars, the rockets could have been up to 24–30 meters long. (Or the rockets could have been even longer if the railroad cars were longer than average, or if the rockets were partially disassembled.) Thus this description does not sound at all like a standard A-4 rocket. Note some observers used "V-2" in a generic sense to refer to any large German rockets, not just the A-4.

What type of rocket was being produced in this underground factory? The most likely possibilities were an 18-meter-long extended A-4 (without wings) or A-9 (with wings), a 21-meter-long extended A-4 or A-9, a 20- to 26-meter-long A-10, or a ∼30+ meter-long A-9/A-10.

Whatever these unusually large rockets were, they were not at the design stage or the prototype stage. Possibly as early as 1943 and definitely no later than mid-1944, they were being mass-produced.

Where are all the wartime German and postwar Allied reports on this underground rocket factory?

Could an industrial archaeological excavation be conducted at the site of this factory now?]

SECRET | 8th ARMY POW CAGE (AIR) 200 MU | TARGET NOTES A/5 4 November, 1944

93

1. **BEUTHEN - UPPER SILESIA, Gasoline Distillation:** P/W was employed in the marshalling yards at BEUTHEN/KARF until 3 August/44. He reports that tank cars filled with gasoline left the BEUTHEN area from the following distillation plants:

Graefin Johanna Grube, in BOBREK-KARF (see Bomber's Baedeker 2nd (1944) Edition p. 62) has two distillation plants (Oefen fuer Schwel Anlagen). These had been built prior to Feb/40, the time when he first started to work at KARF. They were built under army supervision, and were considered a model of efficiency by the Wehrmacht. An average of 6 20-ton tank-cars left the plant each day, for destinations designated only by number and unknown to P/W. They were always marked as a 1st Priority Shipment.

Karsten Zentrum-Grube, (also listed on p. 62 of Bomber's Baedeker) likewise has two distillation plants identical to the above, and with the same capacity. The two factories are only 500 metres apart.

Julienhuette, (also listed on p. 62 of Bomber's Baedeker) likewise has two distillation plants identical to those at Graefin Johanna Grube. This factory lies 1 km to the west of the Graefin Johanna Grube.

None of the above installations had been attacked to 3 August/44 (except for one raid on the Julienhuette in 1942, reportedly by Russian A/C). In periods when there was no alert each of these distillation tanks gave off exhaust gases which burned with a flame that could be seen for miles. Shortly before an air-raid warning these flames were seen to go out, and as this always happened some minutes before the public warning was sounded it was considered locally to be the surest sign of an impending air-raid.

2. **Shell Factory in BOBREK-KARF:** Same P/W who furnished above information states that three 20-ton cars loaded with 12 cm shell casings left the Szikora Gerdys steel mill in BOBREK-KARF each day. These shipments originally went to SKARZYSKO-KAMIENNA near RADOM, but for the last month and a half the shipments were directed to an unknown destination in Germany.

3. **Chemical Factory in HUGOHUETTE:** 3 km north of TARNOWITZ, on the road to GEORGENBERG, there is a village called HUGOHUETTE. 300 metres to the west of this village there is a chemical factory, to which a large new addition was being added during the early part of this year. The product of the factory is unknown, but the work was under the supervision of the Wehrmacht.

4. **Partisan Activity - ~~UPPER SILESIA~~ WARTHEGAU:** Partisan activity ~~in UPPER SILESIA~~ is now reaching sizeable proportions. In June of this year partisans caused

a triple train wreck by throwing a switch on the double track R.R. near Ktobuck. Two freight trains collided, and later a passenger train ~~likewise~~ piled into the wreckage.

5. Under-ground Factory in FRIEDRICHSHAFEN: In Jan/43 P/W visited the site of a large new under-ground factory being built by Dornier at FRIEDRICHSHAFEN. Factory lies between the lake and the road to IMMENSTAAD, on the NW edge of FRIEDRICHSHAFEN. It is covered by a storage yard for wood and other bulk materials, and there is a R.R. spur leading into the underground part. P/W could give no information as to the size of the underground unit, other than to say that it was about the same size as the large Mercedes Factory in STUTTGART. He heard from friends that V-2 was being made there, and that three R.R. cars were necessary to haul away a single V-2 bomb. P/W considered himself an Italian, having been born in BOLZANO, and was obviously trying to give reliable information.

6. A/C Components Factory - BERLIN: The Heinrich H. Kluesendorf Factory, on Citadellan Weg, Spandau, BERLIN, employed 600 in Feb/43 making A/C parts for Junkers. The parts were for A/C motors, but P/W did not know to which factory they were later sent for assembly. P/W did not visit Spandau at the time of his last leave, and had not heard whether the factory is still running to-day. This factory is not listed in Bomber's Baedeker.

Figure E.74: A report of rockets larger than the standard A-4 (V-2) being mass-produced at an underground factory in Friedrichshafen. R. R. Thun. 5th Army POW Cage (Air), Target Notes A/5. 4 November 1944 [AFHRA folder 512.619C-15A 1943–1945; AFHRA A5417 electronic pp. 969–970].

A.D.I. (K) Report No. 113A/1945. Suspected 'V' Weapon Factories—Germany and Poland. [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL]

UNDERGROUND WORKS OBER RADERACH.
(September 1944).

2. A co-operative German P/W, who lived in the Friedrichshafen area until September 1944, said there was an underground factory between two hills to the North West of Ober Raderach village rather less than four miles North North West of Friedrichshafen at 47^o 42' 18" N., 9^o 26' 25" E. This pinpoint is very near that of a site described in a report from Italy dated 24th November 1944 reference MFIU/HQ/CSDIC/12.

3. It was locally rumoured that the Ober Raderach works was closely connected with the Zeppelin works at Friedrichshafen and that "25 ton objects" presumed to be 'V' weapons, were being produced. During the winter of 1943/1944 loud noises similar to those made by a power unit under test emanated from the plant but in about March 1944 there was a loud explosion; thereafter things quietened down more than somewhat.

4. P/W had no idea of how many workers might be employed but said they were all either P/W or German troops undergoing detention and they were never allowed outside the factory precincts.

5. These precincts were, however, extensive, as the 6 ft. wooden fence round the site enclosed both the above mentioned hills and a fairly considerable area of ground. A number of small brick office buildings and barrack huts were visible from the outside but the presence of guards operating under Gestapo supervision discouraged the curious from looking too closely.

SECRET. SECRET A.D.I.(K) Report No. 113A/1945.

THE FOLLOWING INFORMATION HAS BEEN OBTAINED FROM P/W. AS THE STATEMENTS MADE HAVE NOT AS YET BEEN VERIFIED, NO MENTION OF THEM SHOULD BE MADE IN INTELLIGENCE SUMMARIES OF COMMANDS OR LOWER FORMATIONS, NOR SHOULD THEY BE ACCEPTED AS FACTS UNTIL COMMENTED ON IN AIR MINISTRY INTELLIGENCE SUMMARIES OR SPECIAL COMMUNICATIONS.

SUSPECTED 'V' WEAPON FACTORIES - GERMANY AND POLAND.

A number of P/W and Allied nationals recently interrogated in this country and on the Continent have passed on stories about suspected 'V' weapon factories. These are not all very convincing but they may be found to tie up with rumours from other sources or be capable of proof by photographic interpretation.

UNDERGROUND WORKS OBER RADERACH.
(September 1944).

2. A co-operative German P/W, who lived in the Friedrichshafen area until September 1944, said there was an underground factory between two hills to the North West of Ober Raderach village rather less than four miles North North West of Freidrichshafen at 47° 42' 18" N., 9° 26' 25" E. This pinpoint is very near that of a site described in a report from Italy dated 24th November 1944 reference MFIU/HQ/CSDIC/12.

3. It was locally rumoured that the Ober Raderach works was closely connected with the Zeppelin works at Friedrichshafen and that "25 ton objects" presumed to be 'V' weapons, were being produced. During the winter of 1943/1944 loud noises similar to those made by a power unit under test emanated from the plant but in about March 1944 there was a loud explosion; thereafter things quietened down more than somewhat.

4. P/W had no idea of how many workers might be employed but said they were all either P/W or German troops undergoing detention and they were never allowed outside the factory precincts.

5. These precincts were, however, extensive, as the 6 ft. wooden fence round the site enclosed both the above mentioned hills and a fairly considerable area of ground. A number of small brick office buildings and barrack huts were visible from the outside but the presence of guards operating under Gestapo supervision discouraged the curious from looking too closely.

6. With reference to the Zeppelin factory itself a French report on the interrogation of an employee of Bugatti, Molsheim, mentions that some of the Zeppelin shops at Friedrichshafen were being tooled up in 1944 for the manufacture of aircraft torpedoes and that these would be tested on Lake Constance.

GLAMMERT SPINNEREI, MÄHRISCH WEISSWASSER, CZECHOSLOVAKIA.
(December 1943).

7. A Czech P/W had heard from his aunt, who lived at Mährisch Weisswasser, that in December 1943 the Germans had taken over the Glammert spinning mill in that town for "finishing work of a secret nature connected with the present G.A.F. programme".

8. The village of Weisswasser (Bila Voda) lies approximately 18 miles East South East of Zamberk and the spinning mill is located immediately North of the intersection of the main railway line and the road running South through the village, on the western side of this road, at 50° 01' 02 N., 16° 44' 50" E.

Figure E.75: Another report of rockets larger than the standard A-4 (V-2) being mass-produced at an underground factory in Friedrichshafen. A.D.I. (K) Report No. 113A/1945. Suspected 'V' Weapon Factories—Germany and Poland [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL].

Report T.I. 3339 (SD-2621pt/947), Flying Bombs and Rockets. December 1944. [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL]

V-2, V-26, V-32.

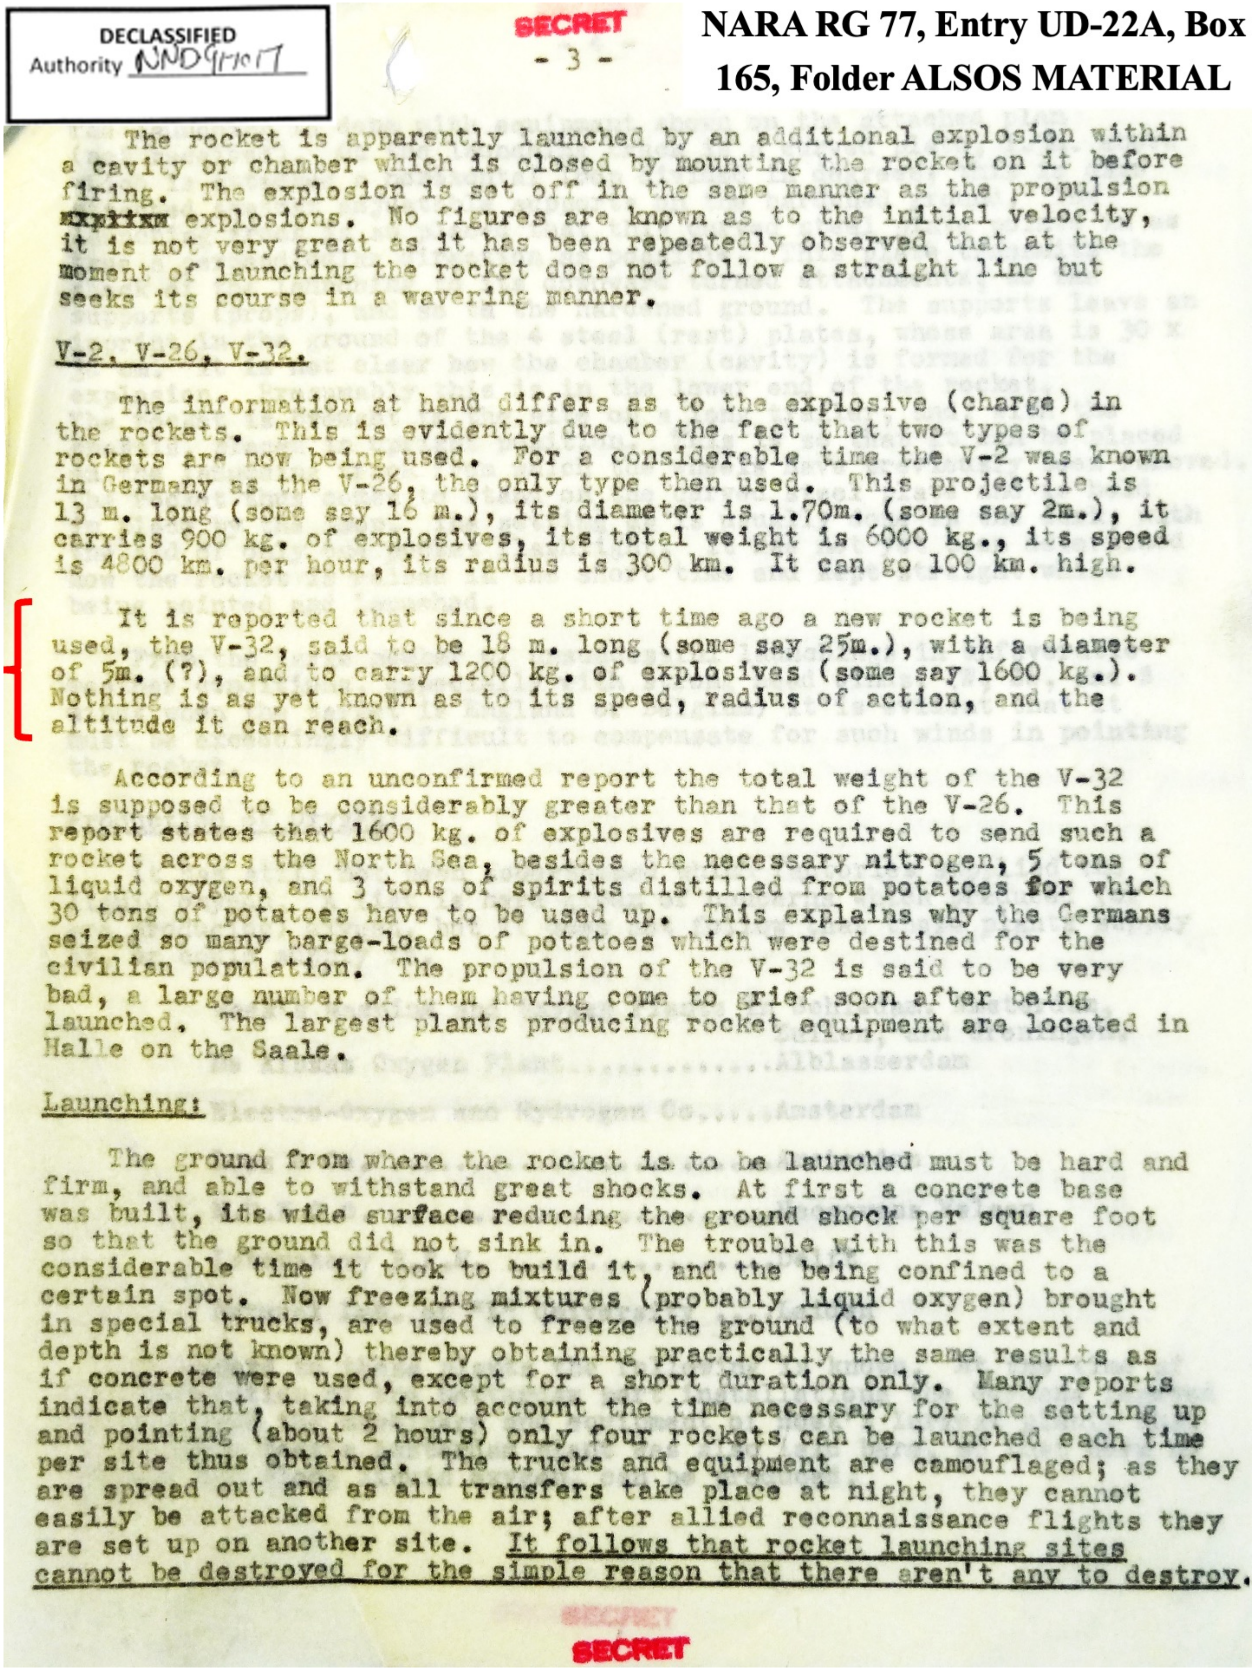
The information at hand differs as to the explosive (charge) in the rockets. This is evidently due to the fact that two types of rockets are now being used. For a considerable time the V-2 was known in Germany as the V-26, the only type then used. This projectile is 13 m. long (some say 16 m.), its diameter is 1.70 m. (some say 2 m.), it carries 900 kg. of explosives, its total weight is 6000 kg., its speed is 4800 km. per hour, its radius [range] is 300 km. It can go 100 km. high.

It is reported that since a short time ago a new rocket is being used, the V-32, said to be 18 m. long (some say 25 m.), with a diameter of 5 m. (?), and to carry 1200 kg. of explosives (some say 1600 kg.). Nothing is as yet known as to its speed, radius [range] of action, and the altitude it can reach.

According to an unconfirmed report the total weight of the V-32 is supposed to be considerably greater than that of the V-26. [...] The propulsion of the V-32 is said to be very bad, a large number of them having come to grief soon after being launched. The largest plants producing rocket equipment are located in Halle on the Saale.

[See document photo on p. 5333.

This is yet another report of rockets larger than the standard A-4 (V-2) being mass-produced.]



DECLASSIFIED

SECRET

- 3 -

NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL

The rocket is apparently launched by an additional explosion within a cavity or chamber which is closed by mounting the rocket on it before firing. The explosion is set off in the same manner as the propulsion xxpixxm explosions. No figures are known as to the initial velocity, it is not very great as it has been repeatedly observed that at the moment of launching the rocket does not follow a straight line but seeks its course in a wavering manner.

V-2, V-26, V-32.

The information at hand differs as to the explosive (charge) in the rockets. This is evidently due to the fact that two types of rockets are now being used. For a considerable time the V-2 was known in Germany as the V-26, the only type then used. This projectile is 13 m. long (some say 16 m.), its diameter is 1.70m. (some say 2m.), it carries 900 kg. of explosives, its total weight is 6000 kg., its speed is 4800 km. per hour, its radius is 300 km. It can go 100 km. high.

It is reported that since a short time ago a new rocket is being used, the V-32, said to be 18 m. long (some say 25m.), with a diameter of 5m. (?), and to carry 1200 kg. of explosives (some say 1600 kg.). Nothing is as yet known as to its speed, radius of action, and the altitude it can reach.

According to an unconfirmed report the total weight of the V-32 is supposed to be considerably greater than that of the V-26. This report states that 1600 kg. of explosives are required to send such a rocket across the North Sea, besides the necessary nitrogen, 5 tons of liquid oxygen, and 3 tons of spirits distilled from potatoes for which 30 tons of potatoes have to be used up. This explains why the Germans seized so many barge-loads of potatoes which were destined for the civilian population. The propulsion of the V-32 is said to be very bad, a large number of them having come to grief soon after being launched. The largest plants producing rocket equipment are located in Halle on the Saale.

Launching:

The ground from where the rocket is to be launched must be hard and firm, and able to withstand great shocks. At first a concrete base was built, its wide surface reducing the ground shock per square foot so that the ground did not sink in. The trouble with this was the considerable time it took to build it, and the being confined to a certain spot. Now freezing mixtures (probably liquid oxygen) brought in special trucks, are used to freeze the ground (to what extent and depth is not known) thereby obtaining practically the same results as if concrete were used, except for a short duration only. Many reports indicate that, taking into account the time necessary for the setting up and pointing (about 2 hours) only four rockets can be launched each time per site thus obtained. The trucks and equipment are camouflaged; as they are spread out and as all transfers take place at night, they cannot easily be attacked from the air; after allied reconnaissance flights they are set up on another site. It follows that rocket launching sites cannot be destroyed for the simple reason that there aren't any to destroy.

SECRET

Figure E.76: Yet another report of rockets larger than the standard A-4 (V-2) being mass-produced. Report T.I. 3339 (SD-2621pt/947), Flying Bombs and Rockets. December 1944 [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL].

Interrogation report of a prisoner of war (PW) who had been employed at Peenemünde as a chemist. MU 500, CSDIC (West), Seventh Army APO 758 US Army, Reference No. 579, Peenemunde Experimental Center (Karlshagen). 14 December 1944. [Published in Georg and Mehner 2004, p. 93; Stevens 2007, p. 237. What is the archival source of this document???]

The V-2 flying bombs are assembled in the EAST Works (see Appendix A) which has about 3,000 engineers and workers. Two types of V-2 have been built: Type A 1 [A-10?], which is about 23 m long and 4.5 m in diameter, and Type A 4, which is about 18 m long and 2.5–3 m in diameter. Only the latter is in mass production. The experimental launching of V-2 used to take place every Saturday afternoon from Mar 43 to Mar 44. At the latter time it was rumored that HITLER had visited the center and had demonstrated his anger at the slow progress of the experiments. From this time on the frequency of the bomb launchings was increased to every other day. When PW left the center in July 44 there were still some launchings which were not successful due to the fact that the bombs were not able to be radio-guided, although they were launched successfully.

[...] PW heard that German technicians intended to launch them to an altitude of 120 km, which would have permitted them to reach NEW YORK. At the height of 15 km the bombs have a range of 500 km. When the bomb drops through the stratosphere to a lower level, it becomes red through friction.

[Various versions of the A-10 design had a length of 20–26 m and a body diameter of approximately 4.15 m (with fins spanning a larger diameter), and were required to achieve enough range to reach New York, so these details are fairly consistent with the prisoner's report.

A-4 had a body diameter of 1.65 m but fins spanning approximately 3.5 m, which may account for the prisoner's description of 2.5–3 m for the diameter. While the standard A-4 length was 14 m, versions of the A-4 (or A-9) with a length of 18 m are reported by a number of sources in addition to this prisoner.

Trajectories in which an A-9 (winged A-4) leveled off at an altitude of 15 km and flew horizontally toward its target, or an A-10-boosted A-9 leveled off at an altitude of 120 km and flew horizontally, were considered in detail alongside better-known trajectories.]

CIOS XXVIII-56. *Rockets and Guided Missiles.* p. 9.

The capacity of the fuel tank was 4,460 litres. Some larger tanks were made for A.4 towards the end of the war, but were never used. (ENG. FINZEL) [...]

Brett Davis. V-2 Plant Survivors Publicize Their Story. *Huntsville Times* 28 February 2000 [http://www.v2rocket.com/start/others/news-archive.html].

"People have now started to realize what happened there," said Alex Baum, who was a member of the French resistance and was captured and sent to the underground V-2 plant. He now lives in California. "We want to make the public more aware," Baum said. [...]

Baum said he remembers von Braun both from Peenemünde and Dora, although he had no contact with him or the other German engineers at the time by orders of the SS. He remembers one day when the top German brass, including Heinrich Himmler, the head of the dreaded SS and the second-ranking official in the Third Reich, visited Peenemünde. Von Braun praised the V-2 to them, Baum said.

"I understand German, too, because I was raised in Alsace-Lorraine (a region of France on the German border)," Baum said. "I could hear von Braun talking about the ultimate weapon that's going to destroy the United States and everything else. We (the prisoners) were not very close, but we could see them." Later, he would see von Braun visit the Mittelwerk, usually in the company of top military officials. "He was very desperate to get this thing going, and he knew exactly what was going on," Baum said.

[Alex Baum remembered that Wernher von Braun eagerly expected the arrival of a new rocket warhead with tremendous destructive power.

Compare Baum's testimony to the incident involving British journalist Gordon Young, who interviewed von Braun and Walter Dornberger at Garmisch in June 1945. They told Young that the V-2 would have soon received a "much more powerful" warhead. Allied censorship forced Young to eliminate any reference to German nuclear weapons at that time, since the U.S. nuclear weapons program was still completely secret. In August 1945, after U.S. nuclear weapons were used on Japan and became publicly known, Young tried to publish a second article reporting what he had learned from von Braun about nuclear-armed rockets. That second article was censored completely; only a brief reference in another article in Young's own newspaper (*Daily Express*) and three short articles in Australian newspapers escaped that second and final censorship (pp. 4679–4681).

Squadron Leader E. J. André Kenny (one of the most important British aerial photo interpreters for Operation Crossbow) confirmed that von Braun "had spoken of atomic energy at Garmisch, in 1945" (p. 5763).

For further evidence of rockets with nuclear warheads, see the summary of the interrogation of engineer Horst Kirfes (p. 4532), as well as the July 1946 *AAF Review* (p. 5038).

For many more references to nuclear-armed rockets that were intended to attack Allied targets during the war, see the list of documents on p. 5821.]

Benjamin Jacobs. 1995. *The Dentist of Auschwitz.* Lexington, Kentucky: University Press of Kentucky. Chapter 16: Dora-Mittelbau [http://nizkor.com/features/dentist/].

"What work are you doing here?" I asked an inmate. [...]

"Have you heard of the German V-rockets? After the Allied bombing destroyed Peenemünde, where they were first built, now we assembled them here, in the Harz mountain caves. At first we worked on the V1, then on the V2, and now," and here he began almost to whisper, "we are beginning to work on the V3."

Colonel Lowell P. Weicker. 1945. Headquarters United States Strategic Air Forces in Europe (REAR), Office of the Director of Intelligence AAF 390, Memorandum to George C. McDonald. 5 January. [Published in Georg and Mehner 2004 p. 203. What is the archival source of this document???]

1. You will recollect that the SHAEF forecast, arrived at after D-day in 1944, placed the capitulation of Germany at the end of December of that year. [...]

3. With the exception of a few modifications and improvements the U.S. Air Forces in this theater are fighting with substantially the same weapons as they used in 1942. [...] This period ended December 31, 1944 with Germany still fighting, but Germany is not fighting with the weapons of 1942. She is leading the world in tested jet propelled airplanes, long range missiles, new type submarines and, in certain classes, better tanks. A large part of her manufacturing facilities have gone underground and she is bending every sinew for the last stand on the Vaterland frontiers.

4. Our Ground Armies, despite superiority in manpower and quantity of equipment, are presently engaged more in defensive than offensive fighting and, unless this state of affairs is quickly changed or the Russians actually drive through to Berlin and victory, we must face the grim expectation of fighting Germany and her new capabilities through greater 1945. [...]

6. CONCLUSION:

a. The war has not terminated in accordance with SHAEF Plans.

b. SHAEF timing has dominated the development of equipment, training progress and establishment of manpower and supply for this theater.

c. The first cycle and period of the war has ended without the capitulation of Germany and with Germany leading in the development of principal new weapons and methods, which will be included in her capabilities during 1945.

7. RECOMMENDATION:

That this Directorate of Intelligence prepare a careful analysis of over-all Germany capabilities for 1945 as they may effect our flying formations and our target systems...

[This is a remarkably frank Allied acknowledgement of the technological superiority of German weapons, even in these final stages of the war.

This request apparently led to the creation of the following 19 January 1945 Commanders Intelligence Digest.]

Headquarters, United States Strategic Air Forces [USSTAF] in Europe, Office of the Director of Intelligence, An Evaluation of German Capabilities in 1945. The Commanders Intelligence Digest. 19 January 1945. [AFHRA folder 519.635 1945 Intelligence Digest; AFHRA A5729 electronic version pp. 255 onward and 561 onward; NARA RG 319, Entry UD-1041, Box 27, Folder 925497]

1. In the following paragraphs are listed the actual or potential weapons which the Germans may use against USSTAF operations in 1945. For the most part they include the so-called V weapons. No consideration is given to those for which there is lacking evidence of possible use for some time to come. [...]

2. V-2:

[...] The V-2, or rocket projectile, with a warhead of approximately one ton, and a current range of 225 miles, is being fired at London at the rate of 180/250 per month, and against Continental ports at the rate of approximately 300 per month.

[...] Larger rockets (68 feet in length as against 45 feet) are known to exist, and may appear in small quantities during the year. They would have a considerably larger warhead. [...]

4. “PHOO” BOMBS: Occasionally reports by pilots and the testimony of prisoners of war and escapees describe this weapon as a radio-controlled, jet-propelled, still-nosed, short-range, high performance ramming weapon, for use against bombing formations. Its speed is estimated at 525 mph and it is estimated to have an endurance of 25 minutes. These bombs are launched from local airfields, and are radio-controlled, either from the ground, or possibly by aircraft. [...]

5. MAGNETIC WAVE: The best information available is from very secret and reliable sources, and forces the conclusion that this weapon exists as a possibility. It is designed to cause failure of various electrical apparatus in aircraft. [...]

7. ATOMIC BOMB: Close check of every report, and close surveillance of the area in which tests are alleged to have taken place lead to the conclusion that such bombs are not a likelihood in 1945.

[See document photos on pp. 5338–5340.

Point 1 above suggests that there is significant evidence for those weapons that are then listed.

Point 2 definitively states that rockets 50% longer than the V-2 (21 m vs. 14 m), and with a warhead “considerably larger” than one ton, are “known to exist.” Are those A-10 boosters, stretched A-4 rockets, or something else?

Point 4 suggests that the mysterious “foo” or “phoo” fighters reported late in the war were a real German anti-aircraft weapon that has never been fully described in publicly available documents; see for example Chester 2007.

Point 5 shows that an electromagnetic pulse directed energy weapon was reported by “very secret and reliable sources.”

Point 7 suggests U.S. knowledge of multiple alleged German atomic bomb tests prior to January 1945, in a particular area that was under close Allied surveillance. This likely means the Baltic coast, including the October 1944 Rügen test.]

UNITED STATES STRATEGIC AIR FORCES IN EUROPE
Office of the Director of Intelligence

19 January 1945

AN EVALUATION OF GERMAN CAPABILITIES IN 1945

PART ONE - INTRODUCTION AND PRINCIPAL CONCLUSIONS

1. The progressive destruction and dislocation of the German military, industrial and economic systems and the direct coordination with land and naval forces is the mission assigned by the Combined Chiefs of Staff to United States Strategic Forces in Europe. It is the purpose of this evaluation to estimate German capabilities for opposing this mission in 1945. The evaluation is divided into eight parts as follows:

a. Part One - Introduction and Principal Conclusions
b. Part Two - Radar
c. Part Three - German Air Force
d. Part Four - Flak
e. Part Five - Passive Defense
f. Part Six - Other Weapons
g. Part Seven - U-Boats
h. Part Eight - Certain Counter-Intelligence Problems

NOTE: For an evaluation of German economy and general war making capacity in relation to the objectives best suited for strategic attack in the accomplishment of USSTAF's mission, reference is made to the exhaustive and authoritative paper in preparation and shortly to be issued by the Combined Strategic Target Committee.

2. PRINCIPAL CONCLUSIONS: The following conclusions are extracted from the seven papers comprising the body of this evaluation.

a. Radar: New German radar equipment is expected during 1945 to give the enemy considerably improved early warning, fighter control, and flak control. This equipment will be exceedingly difficult to jam and will render present jamming technique obsolete. The capabilities of the enemy to oppose strategic attack through this equipment are believed to be materially improved.

b. German Air Force: The highest priorities in the Reich are devoted to a program of producing jet aircraft. The purpose of this program is to regain aerial superiority first over Germany and then over Europe, the armies and the sea approaches to the Continent. The superiority of an air force composed of jet aircraft, in sufficient numbers, is indubitable. It is estimated that at the present rates of production and training, if the program is unchecked, the Germans could possibly have roughly 1,000 jets operational by mid-summer. That quantity in the absence of appropriate counter-measures, could conceivably make further strategic bombardment of Germany too expensive to continue. A corollary aspect of this development is the serious menace to our photo reconnaissance missions which are essential to air intelligence, the strategic bombing program, and indeed to all successful military operations. The improved capabilities of the G.A.F. in 1945 depend largely upon the degree to which the production of jet aircraft can be impeded.

c. Flak: During the latter part of 1944 German Flak defenses materially increased in effectiveness and exceeded the G.A.F. in the amount of damage caused to USSTAF aircraft. It is estimated that with improved

PART SIX - OTHER WEAPONS

1. In the following paragrpahs are listed the actual or potential weapons which the Germans may use against USSTAF operations in 1945. For the most part they include the so-called V weapons. No consideration is given to those for which there is lacking evidence of possible use for some time to come. Both V-1 and V-2 are considered in this analysis because, even though they are, in effect, long-range artillery, they do possess the ability to affect our operations by hitting airfields, and supplies enroute and in concentrations.

2. V-2:

a. Present status. The V-2, or rocket projectile, with a warhead of approximately one ton, and a current range of 225 miles; is being fired at London at the rate of 180/250 per month, and against Continental ports at the rate of approximately 300 per month.

Against London its accuracy is currently rated at 3.2/1,000 per square mile at the main point of impact. Against Continental ports it is estimated at the least 6.1/1,000 per square mile at the main point of impact. The best record was 75 in a twenty-four hour period within a four square mile area of the Antwerp Docks.

b. 1945 Potential: The German plan calls for an increase in monthly production from 600 to 1200. It is known, however, that any increase would be at the expense of the aircraft industry in radio equipment and certain essential components. An increase in accuracy would depend upon increased firings and increased use of already proved radio equipment, without which the majority of firings are conducted today. It is thought unlikely that range will be materially increased. Accuracy begins to fall off somewhere between 165 and 190 miles, and becomes increasingly inaccurate to the maximum of 225 miles. Whether or not V-2 becomes an increased menace in 1945 must depend upon the position of the aircraft industry and its requirements. Its potential lies in stablization of the expanding aircraft program.

Larger rockets (68 feet in length as against 45 feet) are known to exist, and may appear in small quantities during the year. They would have a considerably larger warhead.

3. V-1:

a. Present Status: The so-called Flying Bomb is being fired from launching ramps against Continental targets, ports and supply concentrations, at the rate of 600 per month, and against England by airborne launchings, at the rate of 250 per month. Accuracy against Continental targets is now between 11.0/1,000 per square mile at main point of impact, and against England at 3.3/1,000 per square mile at main point of impact.

b. 1945 Potential: Here again, the German plan calls for an expansion in production, but, as in the case of V-2, this expansion must be at the expense of other vital industries. Authoritative estimates state that airborne launchings against England may reach 450 per month, and that a very substantial increase of launchings on the Continent will take place. On the other hand, the number of He-111s available for airborne launchings is distinctly limited, and the demands of other industries are such that the expanded production may not be carried out as planned.

4. "PHOO" BOMBS: Occasionally reports by pilots and the testimony of prisoners of war and escapees describe this weapon as a radio-controlled, jet-propelled, still-nosed, short-range, high performance ramming weapon, for use against bombing formations. Its speed is estimated at 525 mph

TOP SECRET

and it is estimated to have an endurance of 25 minutes. These bombs are launched from local airfields, and are radio-controlled, either from the ground, or possibly by aircraft. The few incidents reported by pilots indicate no success. They have passed over formations, andperformed various antics in the vicinity of formations. It is believed that in order to be effective some 100/200 would have to be launched against a formation, and it is also believed that they will not be produced in sufficient quantities to prove a real menace in 1945.

5. MAGNETIC WAVE: The best information available is from very secret and reliable sources, and forces the conclusion that this weapon exists as a possibility. It is designed to cause failure of various electrical apparatus in aircraft. Technically it does not appear to be a possible serious threat in 1945. At most it would be effective at a few locations for preventing ground strafing. Evidence to date indicates that it could have little effect against high level attack, since the apparatus would be too cumbersome to permit its use in aircraft.

6. GASES APPLICABLE TO AIRCRAFT: Two types of gases applicable to aircraft are known. One is designed to cause pre-ignition, blowing the heads off cylinders; and the other is designed to break down the viscosity of lubricating oils. Under laboratory conditions, free from operational considerations, these gases are a distinct possibility. It is doubtful, however, that with proper fighter escorts a sufficient concentration of either of these gases could be thrown against our formations to have any serious effect. Similarly, it is doubted whether sufficient anti-aircraft guns are available to produce an effective concentration, and it is probably that any possible concentration would be no more effective than a similar amount of well-directed flak.

7. ATOMIC BOMB: Close check of every report, and close surveillance of the area in which tests are alleged to have taken place lead to the conclusion that such bombs are not a likelihood in 1945.

Says New V-Bomb Now Ready to Cross Atlantic. *Ottawa Citizen* 26 January 1945 p. 17.

STOCKHOLM, Jan. 25—(Reuters)—V-4—new superflying bomb which the Germans claim can hit New York and other points on the eastern North American coast—now is in production and ready for launching across the Atlantic, a German engineer who was one of the principal inventors of V-weapons told correspondents today.

Until a few days ago he was head of an experimental station for V-bombs in Jutland but escaped to Sweden. He first posed as a Danish refugee but after questioning by Swedish authorities disclosed his real identity.

The German was then interned but as his knowledge was useful to the Swedish general staff, they are granting him special conditions and are keeping his name secret.

The V-4 is faster and more accurate than the V-2—and V-3 which is only an improved version of V-2—the engineer said.

It weighs about 15 tons, travels at 1.8 miles a second and attains an altitude of more than 120 miles.

It reaches this height in just over two minutes after being fired at an angle of 75 degrees.

Its great altitude and speed give it increased accuracy and range. At 360 kilometers altitude, the atmosphere is thinnest, so there is practically no friction to impede flight and thus reduce range.

Further, an object of this weight and travelling with this speed cannot easily be diverted from its course by forces such as wind pressure, when climbing or falling.

The great disadvantage of V-4, the engineer said, is that it is difficult to produce in quantity.

The Germans could therefore only send a limited number of bombs against Halifax, New York or such cities.

The Germans will probably reserve it for European targets until their final defeat, when sheer spite may cause them to attack North American cities, he said.

18. V-Weapon against USA

An acquaintance told PW (28 Jan) that the laboratory in SWINEMÜNDE where he worked, experimented with a new rocket missile, resembling V-2, 30 m long 4–5 m diameter. Experiments conducted with 1/25 of the explosive charge produced devastating results. It was intended to use the projectiles in nuisance bombings of the USA.

19. Atom Smasher

PW heard from friends that atom-smashing experiments (conducted somewhere NW of BERLIN) were successful and would result in the perfecting of an atom-disintegrating weapon by May 45.

(Source: San Uffz Theodor GÖRGES) 4 San Bereitschaft Hermann GÖRING Fallsch Corps captured 1 Mar)

[See document photo on p. 2622.

"A new rocket missile, resembling V-2, 30 m long 4–5 m diameter" for "bombings of the USA" sounds like a remarkably good description of the A-9/A-10 (p. 5271). According to this account it was not merely a paper design, but rather it had already progressed to the point of being "experimented with" as of January 1945, and it was intended to be launched from Europe to the United States as part of the war effort within the near future.

Note that the intercontinental rocket was being assembled and tested in Swinemünde (now Świnoujście, Poland), around 50 km from Peenemünde. That would be close enough to Peenemünde to allow for easy transport of materials and personnel, yet far enough away to potentially avoid the close scrutiny of Allied aerial reconnaissance of Peenemünde.

According to this report, the payload for this intercontinental rocket appears to have been a nuclear weapon. "Experiments conducted with" only "1/25 of the explosive charge produced" effects described as "devastating," which could hardly be said of 1/25 of the conventional explosive payload that had been used on rockets up to that point. Moreover, the report specifically referred to an "atom-disintegrating weapon."

This report indicated that the nuclear weapon had already been successfully tested. "Experiments" had already been "conducted" that "produced devastating results." (If the description meant 1/25 of the explosive yield, then plausible numbers are perhaps ∼1 kiloton for the tested version and ∼25 kilotons for the deployed version. "Atom-smashing experiments... were successful" and mass-produced versions for deployment would be ready by May 1945 if the war continued.]

Gordon Gaskill. March 1945. Can Super-Rockets Hit America? *The American Magazine.* pp. 25–108.

I have talked to the leading V-2 authority for the United States Strategic Air Forces in Europe, an officer of high rank and solid reputation who knows all the Allies know about V-2. And we know a surprising amount.

Because of his secret work I am not permitted to reveal his name. But he has given me new and exclusive information which points to only one conclusion: This great rocket is unquestionably the most revolutionary weapon of our time. [...]

This authority, from facts at his command, has calculated for me approximately what kind of rocket might hit New York. Leaving Germany, it would weigh 63 tons, mostly fuel. Its war head would be 7 tons of high explosive. The journey from Germany to New York—about 4,000 miles—would only take 25 minutes. The "motor" would run but 8 minutes of this time. The rocket would climb almost vertically as high as 300 miles above the earth before leveling off sharply, and its maximum speed would be over 9,000 miles per hour, with an added time saving from the earth's rotation.

"I am using New York merely as an example," he said. "The Germans could just as easily fire at Detroit or Chicago or San Francisco, although the error will naturally be greater if they aim farther west."

It still sounded a little Buck Rogers to me and I must have shown it, for he smiled and said, "I know. Only a few months ago a lot of people in Britain were joking about the 'fantastic' rumors of V-1 and V-2. I've helped dig some of those same people out of the rubble. . . . No, I'm afraid such a rocket is really practical. In fact, it's even more practical than the one they're using now against Britain. The curious thing about rockets is that the bigger you build them, the more efficient and satisfactory and inexpensive they become."

I asked him why the Germans hadn't yet used such a rocket, if it was so simple. In answer he pulled out a newspaper clipping, reporting a speech on December 1 by the Nazi Labor Chief, Speer. In an address to the German War Production Board, Speer promised that "V-3" would be ready for firing at America very soon.

[The anonymous expert was likely U.S. Army Air Forces Colonel Donald Putt.

The 7-ton payload is consistent with several other reports of a German intercontinental rocket with a payload of 6 tons (pp. 4338 and 4350–4363). Perhaps 7 tons was an estimate, or perhaps it included 6 tons for the explosive and 1 ton for guidance and/or pilots.

Even 6 or 7 tons of conventional explosive would hardly have justified the enormous amounts of funding and effort required for Germany to develop, build, and launch such a rocket. However, there is evidence that a 6-ton hydrogen bomb was in the late stages of development (p. 4280), and that would have been a far more logical payload.]

Cläre Werner. 16 May 1962 SED Arnstadt transcript. Jonastalverein Archive, Arnstadt. For a discussion of the background and reliability of this document, see p. 4551.

Am 16. März 1945 war ein weiteres Ereignis. Auch hier gab es gegen 21 Uhr Fliegeralarm für unser Gebiet. Hans war dazu wieder mit einigen Freunden auf dem großen Turm, auch wir konnten mit hoch. Diesmal hatten die Leute Ferngläser mit, und es wurde nicht in Richtung des Übungsplatzes gesehen, sondern in Richtung Ichtershausen. Dort wurde es gegen 23 Uhr sehr hell, es war aber nicht so wie die beiden ersten Male davor, sondern es stieg etwas gegen den Himmel mit einem großen Feuerschweif, es ging immer höher, aber es entfernte sich von uns in Richtung Norden. Die Leute fielen sich in die Arme, wir haben es, hurra, wir sind die Größten, wir sind unbesiegbar usw. Die ca. 15 Leute feierten bis zum Morgen. Hans verbot uns wieder alles Gesehene und sagte nur: Wir waren bei einer weiteren Sache dabei, die in der Welt einmalig ist und in jedem Geschichtsbuch stehen wird.

On 16 March 1945, there was a further event. Again, at 21:00 there were air raid warnings for our area. Hans was to return with some friends to the large tower, also we could go up with them. This time the people had binoculars, and watched not in the direction of the training area, rather in the direction of Ichtershausen. There at 23:00 it became very bright, but not like the first two times before, rather it rose somewhat against the sky with a large fire exhaust, higher and higher, but it moved away from us in the direction of the north. The people fell into each other's arms, [saying] we have it, hurray, we are the biggest, we are invincible, etc. The approximately 15 people celebrated until the morning. Hans forbade us again about everything we had seen and only said: We were present at a further event that is unique in the world and will be in every world history book.

[If the rocket was launched at 11:00 p.m., there would have been relatively few witnesses observing the sky at that hour. If air raid warnings were issued to everyone in the area before the launch, there would have been even fewer witnesses.]

Werner Kasper. 16 May 1962 SED Arnstadt transcript. Jonastalverein Archive, Arnstadt. For a discussion of the background and reliability of this document, see p. 4551.

Auf dem Gelände der Polte Rudisleben gab es ebenfalls eine Versuchsanlage und einen Nachbau für Raketenabschüsse, so wie in Peenemünde. Auch dafür mußten wir vershiedene Tanks aus verschiedenem Stahl errichten, die im Gelände jeweils zu Sechsergruppen gebracht wurden. Auch hier waren Sauerstoff, Stickstoff, verschiedene Treibstoffe und auch verschiedene Gase als Füllungen in den Tanks bzw. Behältern in der Größe von 1000 bis 20 000 Liter.

On the grounds of Polte Rudisleben there was also an experimental station and duplicate equipment for rocket firing, as in Peenemünde. We also had to build different tanks from different steel, which were brought there in groups of six. Here too were oxygen, nitrogen, different fuels and also different gases for filling the tanks in size from 1000 to 20,000 liters.

Es wurden verschiedene Abschüsse in Rudisleben durchgeführt. Höhepunkt war der 16. März 1945 in der Nacht gegen 11 Uhr. So einen Feuerschein bei einem Abschuß habe ich nie wieder gesehen. Wir hatten Bereitschaft und waren vor dem Bunker 4 nahe am Eingang, wo wir auch all unsere Werkzeuge hatten. Einige Wochen zuvor hatten wir viel zu tun, vor allem mußten wir eine Menge von Treibstofftanks errichten. Es lagerten ca. 100 Tonnen Treibstoff im Gelände. Von Nordhausen wurden immer nachts Teile gebracht, und Fachleute von Peenemünde und Berlin waren ständig da. Die Wachmannschaft wurde durch SS ersetzt, nur in unserem Bereich war noch die normale Wachmannschaft.

Am 13. März war eine Kupferleitung verstopft, und ich mußte mit einem Kupferschmied ins Objekt. Wir wurden in einem geschlossenen LKW mit SS-Leuten hingefahren. Was wir dort sahen, war einmalig: Diese Aggregate und dieses riesige Ding. Es muß über 30 m hoch gewesen sein und über 4 m im Durchmesser. Unten waren große Flügel und oben kleine Flügel. Darum waren ein großer Holzverschlag und eine Krananlage.

Uns wurde sofort die Arbeit gegeben, und es war für uns nicht einfach, die Kupferleitung in Gang zu bringen. Nach unserer Arbeit wurden wir nicht wieder zu unserem Bunker, sondern in ein Stollensystem im Bereich des Steigers nach Erfurt gebracht. Dieses war so groß, daß darin LKWs fahren konnten. Von einigen hohen SS-Leuten wurden wir belehrt und mußten einige Unterschriften geben, daß wir nichts gesehen haben; falls wir etwas sagen oder erzählen würden, würden wir sofort von der SS erschossen.

Daher nehme ich an, daß am 16. März dieses riesige Ding in die Luft ging, Flugrichtung Norden. Es war einmalig.

Various firings were conducted in Rudisleben. The high point was 16 March 1945 at 11:00 at night. Such a fire light with a firing I have never seen again. We were on duty and were in front of Bunker 4 near the entrance, where we had all our work equipment. A few weeks earlier, we had a lot to do, above all, we had to build a lot of fuel tanks. It took approximately 100 tons of fuel there. Parts were always brought from Nordhausen at night, and officials from Peenemünde and Berlin were there constantly. The security guards was replaced by SS guards, only in our area were there still the normal guards.

On March 13, a copper line was clogged and I had to go with a coppersmith into the base. We were driven there in a closed truck with SS men. What we saw there was unique: These Aggregates [rockets] and this huge thing. It must have been over 30 m high and over 4 m in diameter. Below were large fins and above were small fins. [Two-stage design.] Around it was a large wooden scaffold and a crane system.

We were put to work immediately, and it was not easy for us to fix the copper line. After our work, we were not brought back to our bunker, but rather went to a system of tunnels in the area of Steiger [forest], near Erfurt. These [tunnels] were so large that trucks could drive inside them. We were instructed by some high SS men and had to give some signatures that we had seen nothing; if we were to say or tell something, we would immediately be shot by the SS.

Therefore I take it that on 16 March this huge thing went in the air, flying in the direction of the north. It was unique.

Albin Kummer. 16 May 1962 SED Arnstadt transcript. Jonastalverein Archive, Arnstadt. For a discussion of the background and reliability of this document, see p. 4551.

Das größte Flugobjekt wurde am 16. März 1945 in der Nacht abgeschossen. Dieses Flugobjekt wurde als Wunderwaffe bezeichnet. Es war über 30 m hoch und hatte unten einen Durchmesser von über 4 m. Zum Betanken dieser Waffe wurden zwei Tage benötigt.

Es war einmalig, wie das große Ding gegen den Nachthimmel ging. Die großen Herren von SS und Forschungsrat feierten bis zum Mittag am anderen Tag. Es war wohl ein großer Erfolg der Wissenschaft und der Forschung. Ein zweites Flugobjekt wurde vorbereitet, doch dann waren einige ganz hohe Tiere im Objekt, ich glaube sogar, daß Speer dabei war. Doch dann war auf einmal alles ruhig, das Objekt wurde sogar abgebaut.

The biggest flying object was fired off on 16 March 1945 in the night. This flying object was called a wonder weapon. It was over 30 m high and had a diameter of over 4 m at the bottom. To fuel up this weapon required two days.

It was amazing how the large thing flew against the night sky. The big men from the SS and Research Council celebrated until noon the next day. It was probably a great success of science and research. A second flying object was prepared, but then some very big shots were in the base, I believe even that Speer was there. But then everything was suddenly quiet, the base was even disassembled.

[The given height and base diameter appear to match the description of an A-9/A-10 two-stage rocket.

The statement that it took two days to fuel the rocket (probably with liquid oxygen for oxidizer and either ethanol or fuel oil for fuel in both stages) makes sense from a technical standpoint and seems to support the credibility of Albin Kummer's account.

Kummer's report is highly consistent not only with other accounts within the 1962 SED Arnstadt transcripts, but also with outside statements such as those by Otto Skorzeny (p. 5352) and Werner Grothmann (p. 5355–5359).]

Alfred Gründler. 22 July 1962 SED Arnstadt transcript. Jonastalverein Archive, Arnstadt. For a discussion of the background and reliability of this document, see p. 4551.

[...] Am 1. Juli 1938 wurde die Produktion der Siemens & Halske AG Berlin in Arnstadt aufgenommen. Ab. 1. September 1938 war hier gleichzeitig das Wernerwerk und das Siemens-Schuckert-Werk untergebracht. [...]

Sie beschäftigten sich mit der Entwicklung von Zielsuchgeräten, welche in Flugzeugen und Raketen eingebaut werden konnten. Das erste Gerät war so um die 20 Kilogramm schwer, dann waren sie nur noch zwölf Kilogramm schwer. Bei den ersten Versuchen im November 1944 gab es in Luisental, Neustadt-Glewe, einige Unfälle, aber dann waren die in Ordnung. Im März 1945 (den Tag kann ich nicht mehr sagen) wurde eine A-4 und dann sogar eine A-9/A-10 von der Polte in Rudisleben abgeschossen. Die große Rakete war so gut, sie ging im Norden Norwegens mit einer Abweichung von nur sechs Metern ins Ziel.

[...] On July 1, 1938, Siemens & Halske AG Berlin started production in Arnstadt. From September 1, 1938, the Wernerwerk and the Siemens-Schuckert-Werk were located here at the same time. [...]

They dealt with the development of guidance systems, which could be installed in aircraft and rockets. The first device was about 20 kilograms heavy, then they were only twelve kilograms heavy. In the first tests in November 1944 in Luisental, Neustadt-Glewe, there were some accidents, but then they were fine. In March 1945 (I can no longer say which day) an A-4 and then even an A-9/A-10 were fired off from Polte in Rudisleben. The large rocket was so good, it went to northern Norway with a deviation of only six meters from the target.

[Gründler said that during the war he worked on advanced guidance systems for very long-range rockets at a Siemens facility in Arnstadt, which had begun operation in 1938. He described rocket work there and at Rudisleben, just north of Arnstadt.

U.S. intelligence documents from 1944 and 1946 confirmed that indeed there was a Siemens plant just north of Arnstadt that produced sophisticated guidance systems for very long-range rockets (see pp. 2938–2962, 5348, 5557), and even that the Siemens plant began operation in 1938.

Northern Norway would have been the most logical target for a long-range rocket test. The distance from Arnstadt to the northern coast of Norway is roughly 2200 km or 1400 miles, and northern Norway was sparsely settled. Germany occupied and tightly controlled all of Norway until the end of the war, had military airfields from southern to northern Norway, and also had submarines operating off the coast of Norway. Germany likely had long-range rocket control and tracking stations in Norway.

At an October 1945 press conference, U.S. Army Air Forces General Henry Arnold announced that German rockets “can now travel” 2000–3000 miles and “hit a target on the button” (p. 5454). That public statement suggests that Germany successfully conducted such a test before the end of the war, and that Arnold had obtained evidence detailing that test.]

[Bombing Target] No. 1341, Arnstadt, GL 2618. [AFHRA 25177 electronic version pp. 7–10]

Report No. SKB 45
Report from Switzerland
Information date: early July
Report date: 12 July, 44
Dissemination date: 14 July, 44

It is reported from an entirely reliable source that the direction apparatus for V-2 is manufactured by Siemens at Arnstadt in Thüringen. 45 kms west of Orlamünde (see our SKB43 of 8 July). Approximately every 10th V-1 has a short wave transmitter to control its flight. Siemens still manufactures precision instruments for a/c at Gera.

Date 26 August 1944

TARGET INFORMATION SHEET

[...] (i) The TARGET is the INSTRUMENT WORKS of SIEMENS & HALSKE A.G., at ARNSTADT in Thuringia. It stands in open country, at a point one mile N. by W. of ARNSTADT. [...] The target is adjacent to a sparsely built-up area.

(ii) The construction of this plant is reported to have started in 1938, when both A.E.G. and the SIEMENS & HALSKE A.G., were stated to have erected workshops in the area for the manufacture of precision instruments. It is possible that both plants are included within the target outline. The target is now reported to specialise on the construction of precision instruments more particularly control apparatus for flying bombs and possibly for other secret weapons. The plant is reported to employ nearly 5,000 workers, and is rated at priority 1.

(iii) The total target area (see Illustration 3(m) 18/2) is about 1,000 yards long and 600 yards wide; its major axis running S.W.–N.E. [...] The chief distinguishing feature is the deeply sunk main structure (1), [...] which may be either the foundation for a building still to be completed, or a roof of a possible underground factory. The large spoil heaps (3) together with buildings (4), (5), and (6) alone stand out within the general target outline. [...]

Figure E.82: U.S. Army G-2 intelligence messages from 8 April 1945 describing a large installation at Rudisleben and Ichterhausen [NARA RG 407, Entry NM3-427, Box 12365, Folder 604-2.3 (1688-4) G-2 Jrnl File 4th Armd Div. 7–8 Apr 45]. What exactly did U.S. forces discover there? Where are their reports?

SS-Obersturmbannführer Otto Skorzeny. [Skorzeny 1995, pp. 161, 169]

In October 1944, after the Budapest operation, I flew once again to Führer Headquarters in East Prussia. Preparations were just being made for the Ardennes offensive and Hitler wanted to give me his instructions for Operation Greif.

[...] He assured me that the German Army would triumph in the end in spite of treason and mistakes. This offensive would be successful. Apart from that, "new, truly revolutionary weapons would take the enemy completely by surprise."

There was much talk about German "secret weapons" at this time, and Dr. Goebbels' propaganda did its best to nourish these rumors. [...] However most talk was about another, terrible weapon that was supposed to be based on artificially produced radioactivity.

[...] Included in the V-weapons program was the construction of a rocket capable of bombarding New York or Moscow. This rocket was practically finished at the end of March 1945 and could have gone into series production beginning in July.

[...] I could go on and list a whole series of other new weapons which were designed and built by us during the war.

Henry Picker. 2009. *Hitlers Tischgespräche im Führerhauptquartier.* 2nd ed. Berlin: Propyläen-Taschenbuch bei Ullstein.

[See pp. 4635–4639 for excerpts from this source regarding the development of both fission bombs and intercontinental rockets to carry them.

Henry Picker (German, 1912–1988) was a lawyer whom Hitler invited to attend and take notes on many of his mealtime meetings and conversations. After the war, Picker published those notes, along with his own postwar commentary, as *Hitlers Tischgespräche*, or *Hitler's Table Talk*. Many former officials of the Third Reich vouched for the accuracy of Picker's recollections and comments. Picker stated that:

- A fission bomb was successfully developed and was designed to be delivered by a rocket such as the A-9.
- The A-9 rocket was intended to strike targets in the United States. To achieve that sort of range, the A-9 would have had to be launched on top of a larger A-10 first stage. Thus whenever Picker mentioned the A-9, he was apparently referring to the complete A-9/A-10 intercontinental rocket.
- Prototypes of the A-9/A-10 rocket were completed and ready for launch before the war ended.
- Mass-production of the A-9/A-10 was planned and facilities were built, but those operations were interrupted by the end of the war.
- Hitler considered it vital for the German military to hold geographical areas that were closely associated with the nuclear weapons and intercontinental rocket programs until those weapons could be used. Those areas included Silesia, Bohemia, Thuringia, and the Berlin area.]

U.S. astronaut Gordon Cooper. 2000. [Cooper and Henderson 2000, pp. 148–155]

Wernher [von Braun] was brilliant, as one would expect, but I also found him to be a marvelous conversationalist, raconteur, and genial host... On many occasions, I sat at the bar in his home all night long talking space until the sun came shining in the windows... He regaled me with tales of his life in Germany, before and during the war... Then there was Joaquin "Jack" Keutner [actually spelled Joachim Kuettner], with whom I worked in the early days of Mercury on the Redstone rocket program. Jack had some hair-raising flying stories to tell.

At war's end, a manned V-2 was sitting on the pad at Peenemünde, all tested out, fueled up, and ready to go. It would have been launched on a low-energy easterly orbit, Jack explained. The plan: to drop a warhead on New York City. That 1945 manned rocket flight—sixteen years before the first U.S. manned rocket flight—came within a week or so of being launched.

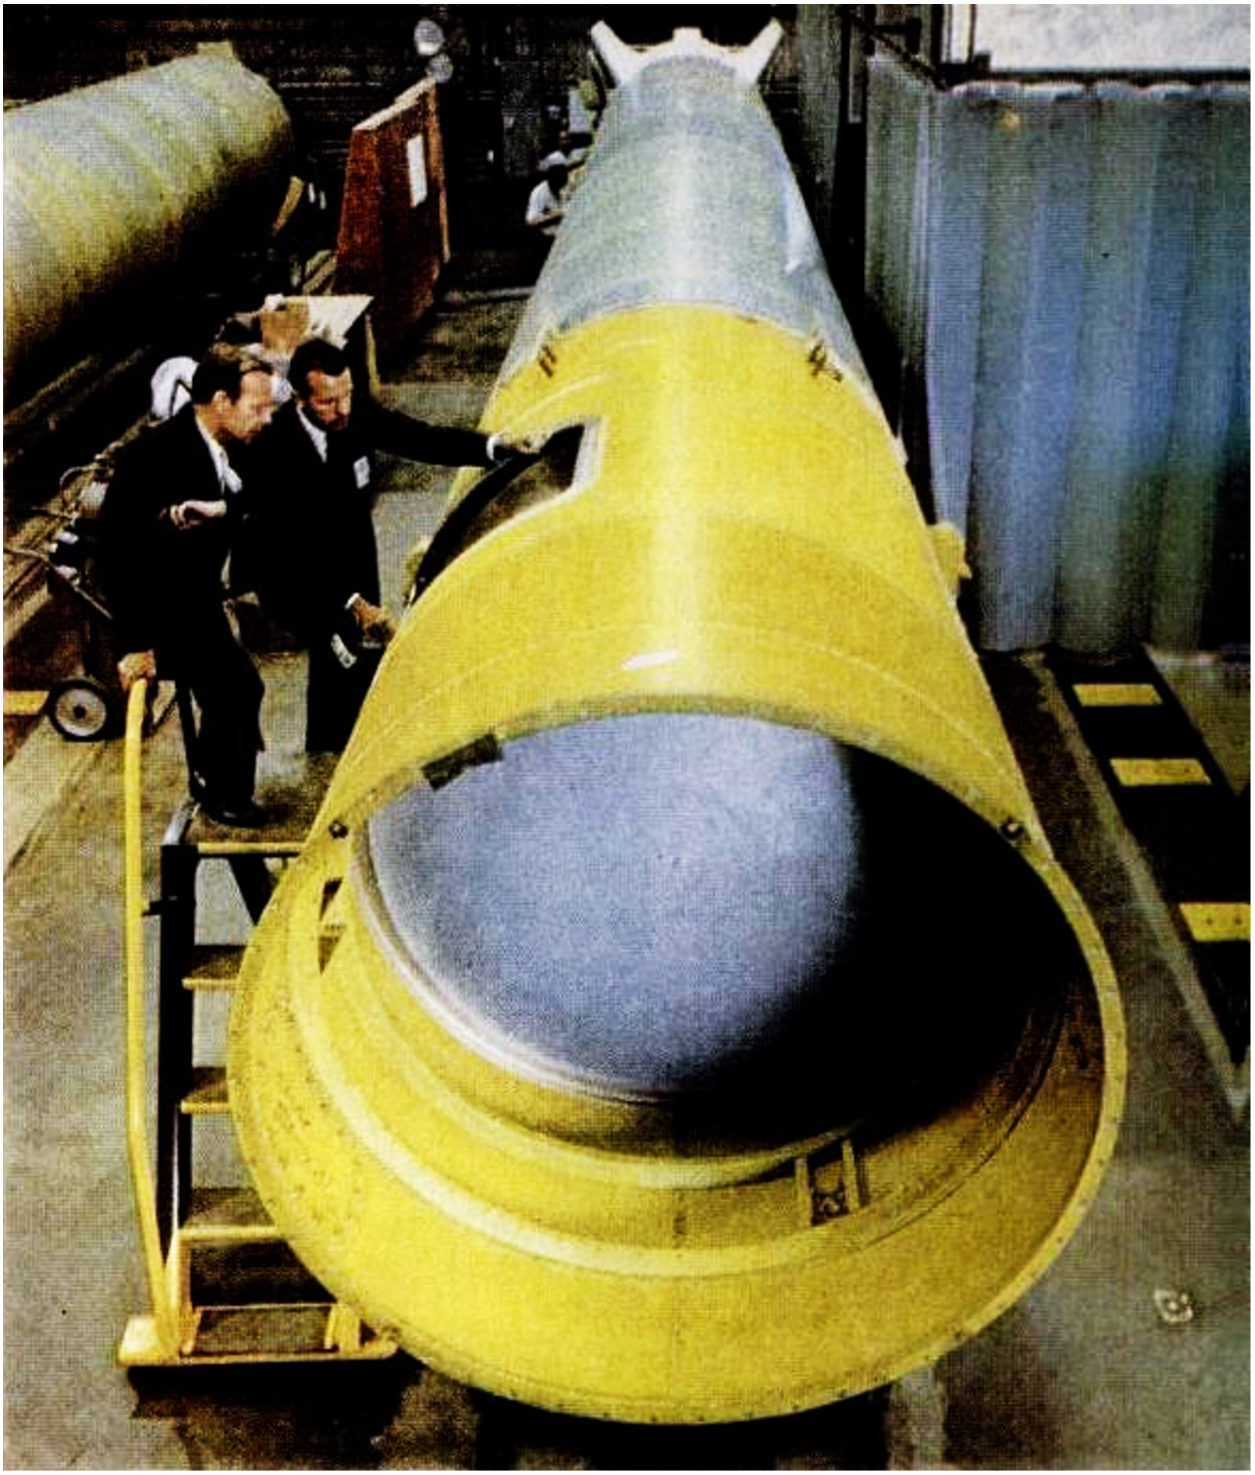
Werner confided to me that the Germans were testing more than rockets at Peenemünde. "Some of the craft we were developing," he said, "were far ahead of anything the rest of the world had or knew about." "You mean jets?" I asked, thinking of the Luftwaffe's Me 262, the world's first jet fighter. He smiled a scientist's knowing smile. "You could almost not refer to them as planes. We flew several craft that were totally different. Very advanced principles were involved."

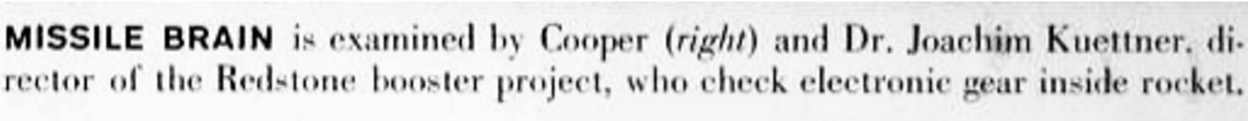
According to Jack, who flew some of these advanced craft, they included saucer-shaped vehicles with double intakes and counter-rotating fans and disks and some with advanced propulsion systems. Jack said they had flown successfully. None of these craft surfaced after the war. Wernher and Jack were unclear about whether any of them had survived the war's last hectic days.

[Cooper had a reputation for telling apparently unsubstantiated UFO stories. At a minimum, Cooper's account of this German rocket project requires some correction: the rocket would likely have been moved from its original development location at Peenemünde to a different launch site by spring 1945, would have been a V-2 variant (A-4b or A-9) on an A-10 booster, and would have been fired westward, and the saucer story invites suspicion.

However, the claim that a manned rocket targeting New York was nearly ready for launch agrees with many independent sources (e.g., pp. 5352, 5355–5359, 5365–5403, 5444–5450), and Kuettner and von Braun are plausible sources for Cooper's information.

Dr. Joachim Kuettner was selected by Wernher von Braun as the project manager for Mercury-Redstone, the first U.S. manned suborbital flights. His previous qualifications were succinctly stated as being a test pilot for high-altitude gliders in Germany during the war. Was he directly involved in a manned suborbital A-9 project?]





MISSILE BRAIN is examined by Cooper (*right*) and Dr. Joachim Kuettner, director of the Redstone booster project, who check electronic gear inside rocket.

Figure E.83: Gordon Cooper and Joachim Kuettner examining a Redstone booster in 1960 [Gordon Cooper 1960].

Heinrich Himmler's chief adjutant Werner Grothmann on advanced rockets [Krotzky 2002]. For a discussion of the background and reliability of this source, see pp. 3396–3397.

[S. 9] Dabei fand ich es doch amüsant, dass ausgerechnet unser bestes Stück, die Riesenrakete, die nach Amerika fliegen sollte, gerade in einer Anlage gebaut wurde, die überhaupt nicht groß war. Na ja, das waren ja auch erst mal die Prototypen für die Flugversuche. Der Serienbau wäre dann näher am Truppenübungsplatz vorgesehen gewesen, wo es eine gute Möglichkeit gab, die enormen Dinger bis zur Flugklar-Meldung in einer Bodensenke zu tarnen. So hätte man die Rakete in einer sehr großen Anlage gebaut, in die eigentlich auch die Produktion einer der Atombombenserien hineinkommen sollte. Das wäre zwar auf zwei unterschiedlichen Geschossen geschehen, aber man hätte dann für beide Teile einen gemeinsamen Weg gehabt. Warum Gerlach sich da quergelegt hatte, ist mir bis heute nicht klar. Es kann sein, dass Himmler mit seiner Einschätzung richtig lag, Gerlach hätte doch zu große Nähe zu uns gemieden, weil er seine eigenen Pläne verfolgen würde. Denn das war ja klar: Die Raketenproduktion, gerade für die Amerika-Rakete, war unsere eigene Sache, die hätten wir auch nicht mehr aus der Hand gegeben. Das war alles unter unserer Kontrolle. Wenn jetzt eine der beiden durchkonstruierten Atombombensorten im selben Komplex hergestellt und zusammengebaut wird, konnten wir den Schutz der Anlage viel effizienter gewährleisten.

[p. 9] I found it amusing, however, that our best piece, the giant rocket, which was to fly to America, had just been built in a plant that was not big at all. Well, those were the prototypes for the flight tests. The mass production would then be closer to the military training base [Ohrdruf], where there was a good possibility to camouflage the enormous things in a depression up to the launch. So the rocket would have been built in a very large plant, which was also supposed to produce one [kind] of the nuclear bombs. This would have happened on two different floors, but then there would have been a common path for both components. Why Gerlach was involved there, is still not clear to me today. It may be that Himmler was correct in his estimation that Gerlach would have avoided too much proximity to us because he would pursue his own plans. Because that was clear: the rocket production, especially for the America rocket, was our own thing, we would not have given it away. It was all under our control. If now one of the two kinds of atomic bombs was built and assembled in the same complex, we would have been able to ensure the protection of the system much more efficiently.

[S. 11] Gerlach ist aber erst dann zu Bormann gefahren, nachdem wir den ersten gelungenen Start unser Grossrakete oder der grossen Rakete für die Entfernung von Thüringen bis London, das war auch eine Neuentwicklung, mitbekommen haben. Das war am 16. März. Das werde ich nie vergessen, da riefen Leute bei Himmlers Stab an, von denen hatte ich noch nie gehört und taten so, als hätten wir jetzt den Krieg gewonnen.

[p. 11] Gerlach did not go to Bormann until we got the first successful launch of our big rocket or the big rocket for the distance from Thuringia to London, which was also a new development. That was on March 16th. I will never forget that, when Himmler's staff got phone calls from people, whom I had never heard of before and who acted as if we had now won the war.

[S. 10] Zur Bezeichnung V 4 kam man wegen den gedanklichen Nähe zur A 4, also der V 2. Das war die echte Langstreckenrakete für Amerika. Dabei hätte es von Thüringen aus nur bis an die Ostküste gereicht, aber dort lagen ja die für uns wichtigen Städte. V 4 hatte man gewählt, weil es ja im Grunde eine Weiterentwicklung der V2 war, wenn auch mit zwei Stufen und mehr als der doppelten Höhe, aber nicht mit höherer Nutzlast. Der erste scharfe Schüß war eigentlich mit voller Ladung für Oktober 45 vorgesehen. Nach dem Test der Versuchsatombombe im März 45 und als man sehen könnte, dass die front nirgegendwo mehr hielt, hatten Hitzköpfe von der politschen Seite einen Angriff mit dem Prototyp und einer eilig zusammengebauten Uranbombe gefordert. Das war aber niemand von uns und ist auch ganz kalt abserviert worden, wie ich vorhin sagte. Außerdem wäre es ein lächerliches Unternehmen geworden, weil das Material nicht gereicht hätte und auch die Rakete noch nie getestet worden war.

[p. 10] One arrived at the designation V 4 because of the mental proximity to the A 4, or the V 2. This was the real long-range rocket for America. From Thuringia it would have reached only the east coast, but there lay the cities that were important to us. V 4 had been chosen because it was basically a further development of the V2, albeit with two stages and more than double the height, but not with a higher payload. The first attack with full cargo was actually scheduled for October 45. After the test of the test bomb in March 45 and when one could see that the front was no longer held anywhere, hotheads from the political side had demanded an attack with the prototype [America rocket] and a hastily assembled uranium bomb. But that was none of us, and it was quite opposed, as I said before. In addition, it would have been a ridiculous attempt because there was not enough [fissionable] material and the rocket had never been tested.

[S. 18] Im Februar oder Anfang März war intern noch mal die Losung bekräftigt worden, den ersten Angriff auf Amerika noch im Oktober durchzuführen. Bei der Beratung dazu lagen Papiere vor, die Skorzeny für die Raketentechniker zusammengeschrieben hatte, also er hatte das sicher nicht selbst geschrieben, sondern jemand von seinen Leuten, und es sind auch Erklärungen von den Wissenschaftlern besprochen worden. Es sah so aus, dass wir das hinbekommen würden. Die große Rakete war ja schon längere Zeit im Bau und die sie gesehen hatten, also die Teile dafür, waren doch beeindruckt. Wir waren jedenfalls von der technischen Vorbereitung für die Waffe un den Träger her überzeugt, dass es dann klappen wird. Früher wäre es keinesfalls gegangen. Ich kenne einiges von der Löiteratur, die dazu so überzogene Angaben macht. Die Autoren übersehen nur, dass man einen umfassenden Angriff auf Städte in Amerika nur mit strategischen Waffen führen kann, nicht mit taktischen. Dann musste auch die Technik sicher funktionieren. Stellen sie sich vor, man wirft das ‘Ei’ über New York ab und es zündet nicht! Am Ende liefern es die Amerikaner vier Wochen später bei einem selbst ab. Eine Schwierigkeit bestand ja auch darin, das Gesamtgewicht für die große Bombe zu reduzieren. Es war wohl von den Ingenieuren immer wieder verlangt worden, den Durchmesser und das Gewicht zu reduzieren, wobei ich glaube, dass sich das auf einen ganz bestimmten Bombentyp bezog, denn da hörte und sah ich später schließlich etwas, wo ganz klar war, dass bei dem Ding der Durchmesser wahrscheinlich nicht das Problem gewesen sein konnte. Jedenfalls ging es um den Platzbedarf und die Unterbringungsmöglichkeiten in der Raketenspitze und natürlich auch um die Nutzlast. Das war ja ein wichtiger Faktor, weil der die Reichweite beeinflusste. Übrigens war das auch ein Thema für die Luftfahrt-Ingenieure bei Messerschmitt und Heinkel.

[p. 18] In February or early March, the goal of the first attack on America in October was reaffirmed internally. In the consultation there were papers that Skorzeny had put together for the rocket technicians, or he certainly had not written them himself, rather someone from his people, and explanations were also discussed by the scientists. It looked like we could do it. The large rocket had already been under construction for a long time, and those who saw it, or the parts for it, were impressed. We were certainly convinced of the technical preparation for the weapon and the carrier, that it would then work. In any case, we were convinced of the technical preparations for the weapon and the launch vehicle, that they would work out. It could not have happened sooner. I know some of the literature, which makes it such exaggerated claims. The authors just overlook the fact that a comprehensive attack on cities in America can only be done with strategic weapons, not with tactical ones. Then also the technology had to work safely. Imagine if you throw the ‘egg’ over New York and it does not detonate! In the end, the Americans would deliver it four weeks later on their own. One difficulty was also to reduce the total weight for the large bomb. It had been asked by the engineers again and again to reduce the diameter and the weight, which I believe involved a certain type of bomb, because when I finally heard and saw something, it was quite clear that the diameter of the thing probably could not have been the problem. In any case, it was about the space requirements and the accommodation possibilities in the rocket nose and of course also the payload [mass]. This was an important factor, because it affected the range. By the way, this was also a topic for the aviation engineers at Messerschmitt and Heinkel.

[S. 33] Den Russen fiel dann mehr in die Hände als wir hofften. Zum Beispiel der Prototyp einer künftigen Rakete, zu der allerdings die Amerikaner zuvor die Konstruktionsunterlagen erbeutet hatten.

[p. 33] The Russians found more [in Thuringia] than we hoped. For example, the prototype of a future rocket for which, however, the Americans had previously captured the design documents.

[S. 48] Wir konnten da nichts erreichen bis auf den dringenden Wunsch Himmlers, wir brauchten schnellstens eine Rakete, die bis Amerika fliegen kann. Die Leute dort waren aber sehr zurückhaltend. Was uns überraschte, war dann allerdings folgendes. Ich glaube, es war von Ploetz, der hatte wohl persönlich Beziehungen zu jemandem aus der Peenemünder Gruppe und Kammler darüber informiert, dass nach seiner Kenntnis die Planungen für eine Rakete mit übergroßer Reichweite eigentlich fertig sind und dass man mit etwas gutem Willen schnellstens damit beginnen könnten, die in die Realität umzusetzen. Kammler hat sich das angehört und dann nach Rücksprache mit Himmler vorgeschlagen, das Konzept von unseren eigenen Raketenleute noch mal durchrechnen zu lassen. Die haben dann nach einiger Zeit gemeldet, dass man in Peenemünde ganz solide gearbeitet hat und daß diese Rakete theoretisch alles erfüllen würde, was sie sollte. Ich glaube, damals war die Rede von gut 4000 km Flugweg und eine Tonne Fracht. Das weiß ich aber nicht mehr so genau, weil es noch ein Parallelprojekt gab, für andere Werte vorgesehen waren.

[p. 48] We could not achieve anything except the urgent wish of Himmler. As soon as possible, we needed a rocket that could fly to America. The people there were very cautious. What surprised us was the following. I think it was von Ploetz, who had been personally in contact with someone from the Peenemünde Group, and informed Kammler that, to his knowledge, the plans for a rocket with a very long range were actually finished and that with a little good effort, they could begin as soon as possible to translate that into reality. Kammler listened to this and then, after consultation with Himmler, suggested that the design of our own rocket people be calculated again. They then reported after some time that they had worked very hard in Peenemünde and that this rocket would theoretically fulfill everything it should. I think at that time there was talk of a good 4000 km of range and a ton of payload. But I do not remember that exactly because there was a parallel project that was intended for other values.

[S. 48] Ich meine, wir hatten wirklich gute Leute in unseren eigenen Projekten, und die hatten wieder recht gute Kontakte nach Peenemünde, aber die konnten auch nur das bestätigen, was Kammler aus Peenemünde hörte: Entweder steuert jemand die Rakete ins Ziel, oder die muß vollautomatisch gehen. Himmler war skeptisch, ob ein Pilot bei der Geschwindigkeit überhaupt reagieren kann. Ich meine, die Rakete sollte ja mit etlichen Tausend Kilometern fliegen. Dann gab es auch gar keine Fernsteuerung, die auf die Entfernung wirklich sicher funktionierte. Da hatte Himmler schon früher mal mit Ohnesorge darüber gesprochen und ich glaube, der hat dazu auch was arbeiten lassen. Was sich da ergeben hat, weiß ich aber nicht. Nur an eines kann ich mich noch erinnern, nämlich unsere Raketenleute hatten ja eine kleine Abteilung von, heute müsste sagen Elektronikern, die haben zur völligen Überraschung von uns und auch von Ohnesorge im Winter 44 eine Sende- und Empfangsanlage entwickelt, die man nicht mehr stören konnte, weil sie selbständig dauernd die Funkfrequenz änderte. Außerdem war die ganz klein, richtig winzig. Die hatte nur ungefähr ein kg, der Empfänger meine ich. Wie die das geschafft haben, diese Technik zu verkleinem, ist mir unbekannt. Himmler aber Befehl gegeben, Ohnesorge den Prototyp zu zeigen. Ob das geschehen ist, kann ich nicht sagen. Ich weiß auch nicht, ob der Sender überhaupt auf die Reichweite bis Amerika ausgelegt war. Nach Krieg hörten wir dann, die Amerikaner hätten den Transistor erfunden. Das hat wohl einige von unseren Leuten sehr aufgeregt, weil der doch von uns stammte. Ein Bekannter sagte mir dazu, bei uns hätte der Transistor "Sperrschicht-Halbleiter" geheißen. Der war von einem Professor an einer technischen Hochschule erfunden worden. Es kann sein das war Aachen.

[p. 48] I mean, we had really good people in our own projects, and they had good contacts again to Peenemünde, but they could only confirm what Kammler heard from Peenemünde: Either someone pilots the rocket into the target, or it must be fully automatic. Himmler was skeptical whether a pilot could react at all at that speed. I mean, the rocket was supposed to fly several thousand kilometers. Then there was no remote control at all, which really worked safely at that distance. Himmler had already talked to Ohnesorge about this and I think he had something worked out. But I don't know what came of it. I can only remember one thing, namely that our rocket people had a small department of, today I would have to say electronic engineers, who, to the complete surprise of us and also of Ohnesorge, developed a transmitting and receiving system in the winter of 44, which could no longer be jammed, because it constantly changed the radio frequency on its own. It was also very small, really tiny. It weighed only about one kilogram, the receiver I mean. How they managed to miniaturize this technology is unknown to me. But Himmler gave orders to show the prototype to Ohnesorge. Whether this was done, I cannot say. I also don't know if the transmitter was even designed to reach America. After the war, we heard that the Americans had invented the transistor. That must have upset some of our people very much, because it came from us. An acquaintance told me that in our country the transistor was called a "junction semiconductor." It had been invented by a professor at a technical university. It may have been Aachen.

65 Polish Civ rptd formed conc camp of 6000 was located at CRAWINKEL J1547 where they were used to dig tunnel for underground factory to manufacture V-1 rockets (no rockets have been made there to date)/GOSSEL J1949 camou[flaged] completed factory no pers allowed near this place which is located about 2 mi N of GOSSEL/on 3 Apr was manufacturing V-1s and experimenting with V-3s.

G-2 Periodic Report No. 177. 7 April 1945. [NARA RG 407, Entry NM3-427, Box 12342, Folder 604-2.1 G-2 Periodic Reports 4th Armored Div 1 Jan–18 May 45]

Murdercamp, vic[inity] OHRDRUF: A PW, NCO, rpts that a Concentration Camp of political prisoners, existed in the vic of OHRDRUF. According to stories told him by members of the guards, several thousand persons were killed during this winter at the camp. The PW himself happened onto an open mass grave some weeks ago, and he states that he saw nude bodies laying in lakes of blood. The PW further rpts that many, or perhaps all, of the bodies were exhumed lately and burned in the woods, vic J 115565. On 28 Mar 45, PW believes, several hundred of the political prisoners were still alive. He further states that guards in part belonged to the SS Das REICH and in part to SS LEIB-STANDARTE Adolf Hitler.

[...] The entire area btwn OHRDRUF–SCHWABHAUSEN–WOLFIS–WECHMAR (J 1156) was a tk troop drill and maneuver ground. PW was told by an ordnance man stationed at OHRDRUF that from here a new secret wpn will shortly rise (wird steigen). It is believed that the entire area should be very thoroughly examined for new material. If any of the above mentioned political prisoners can be found alive, interesting evidence should also be forthcoming. (Source: 89 Inf Div Per Rpt No. 27). [...]

Annex No 1 [...] One of the most ridiculous actions of the supreme command (Nazi regime) is the insistence upon the fighting in the far flung areas such as in the BALTIC States, in ITALY, and also the maintenance of troops in NORWAY and DENMARK. It is deemed a disgusting order to see these forces ill placed with the advances of our troops over the RHINE barrier.

G-2 Journal 80th Infantry Division, 1905 09 Apr 45, Gotha, Page No 1068. [NARA RG 407, Entry NM3-427, Box 10127, Folder 380-2.2, G-2 Jnl—80th Inf. Div. Apr 45. G-2 Journal]

Fr 318: RJ at (127489) entrance to underground plant. French workers going from RJ to WOLFIS (1450) were escorted by armed guards, not allowed to look right or left. 300 meters N of STUTZHAUS (105470) is entrance to 105 plant, working last week. Area at (135495) considered to be very important production area. Rpt from 318th MG O.

[These Modified British System coordinates in the Nord de Guerre Grid all correspond to locations approximately 1–4 km southwest of the town of Wölfis, very close to the small city of Ohrdruf in Thuringia.

The belief that “a new secret weapon will shortly rise” from this area could be a reference to advanced rockets and/or nuclear weapons, and there is evidence that both were being developed and tested in this area.

U.S. Colonel Robert S. Allen visited this area in April 1945 and described underground installations that were numerous, massive, and highly sophisticated (p. 4569).

See the map in Fig. E.86 for the areas still held by the German military at the end of the war, as mentioned in the above report. These areas were fiercely defended and likely held secret weapons that Germany still hoped to deploy, such as long-range rockets, long-range jets, and nuclear weapons.]

U.S. Army 89th Infantry Division. G-2 Message Summary. 8 April 1945. [NARA RG 407, Entry NM3-427, Box 11005, Folder 389-2.2 G-2 Jrnl File—89th Inf Div. 8–9 Apr 45]

8 April 45

From 353:

Displaced persons report underground factory in hill 315 at J869451. Entrance on south side of hill. Factory employs some twenty to thirty thousand Russians, Poles, French, etc. They are making the V-4, which is a two man rocket of some sort. Partial assembly at this factory and weapon then is sent to WEIMAR J5271. During the time the source of this information worked at this factory, approx one week ago, there had been no bombing.

More information later after a complete interrogation.

Tuxedo 2

[Please see photos of the G-2 messages from 8 April 1945 on pp. 5368–5373.]

[At NARA RG 407, Entry NM3-427, Boxes 11005 and 12365, I found many versions of this U.S. Army message, including copies from the 89th Infantry Division unit that actually originated the message, a copy from another unit that apparently received the report by radio, and copies echoing up and down the chain of command. The details are the same in all of them, except what is apparently the first message (Fig. E.87) says "Gadget holds 2 men," which clarifies that this was a rocket large enough to hold two men, not a rocket small enough to be set up and launched by two men. Unfortunately I could find no further details, and no follow-up reports—no "complete interrogation" of the displaced persons as promised, and no reports of Americans visiting the V-4 factory themselves.

The J869451 coordinates are the same in all of the messages (except the coordinates 869541 that were initially written down and then crossed out and replaced in the first message). That appears to be Modified British System coordinates for the Nord de Guerre Zone, as confirmed by the J5271 coordinate for Weimar. Using the website tool http://www.echodelta.net/mbs/eng-translator.php, Modified British System coordinate wJ869451 in the Nord de Guerre Grid corresponds to a location just south of Dreitzsch, and approximately 3 km east of Neustadt an der Orla. The only other clue is that the entrance was on the "south side" of "hill 315," referring to the elevation of the location.

It is interesting that the V-4 factory coordinates are given with 100-meter precision (J869451), much more precise than even the Weimar coordinates (J5271, with only 1-km precision). That seems to show a remarkable confidence in the location, most likely either from maps that the escaped prisoners brought with them, or from the escaped prisoners pointing to their former home on maps that the U.S. Army had.

Figure E.88 shows adjacent sheets R-6 (above) and S-6 (below) of the GSGS 4416 map used by the U.S. Army, covering the relevant part of Thuringia. In what was apparently the original report (Fig. E.87), the coordinates for the two-man rocket factory were first given as 869541 (above), then as 869451 (below), 9 km due south of the first location. There is no "hill 315" near either location, and neither of these specific locations seems like a very promising site for a massive underground factory.

However, this general location does seem plausible, since there were a number of other known German research and development facilities above or below ground near that area, including for example:

- A factory for making large rockets at Pössneck, 13 km from Neustadt an der Orla, which may or may not have been the same rocket factory mentioned here (p. 5375).
- Factories in Neustadt an der Orla that just happened to have world-class expertise at making nickel membrane filters for gaseous diffusion uranium enrichment (p. 3633).
- The massive Kahla REIMAHG underground jet factory approximately 15 km to the west (pp. 5214–5217).

- Several other factories in or near Neustadt an der Orla.[2]

Could the V-4 site be located somewhere in that area? We have two approximate alleged locations, the approximate hill elevation, the fact that the main entrance was on the south side of the hill, and the presumed fact that that entrance would likely have been adjacent to a railroad track that existed at that time in order to bring large amount of supplies in and to ship partially completed V-4s to Weimar.

At NARA I also photographed as many other relevant Army documents as I could, for several days before and after this report. When this report was filed on 8 April 1945, the U.S. Army units involved were well to the west of these coordinates. Based on the Army's location, and the fact that the message says "Displaced persons report...," the J869451 location appears to have been given to the U.S. Army by French/Polish/Russian prisoners who escaped from there and fled toward the Americans. It is possible that the prisoners did not give exactly the right location, or that due to language differences the Army misunderstood the location, or that someone wrote down the coordinate numbers incorrectly or in the wrong order. Then those same coordinates got repeated in all the messages. Perhaps the rocket factory was not around Neustadt an der Orla, but rather in some entirely different region.

In these NARA files, I could not find any further reports about the V-4 factory. If the U.S. Army wrote a report, it might still be classified and not in the publicly available files. Or perhaps some other American team actually went into the factory and wrote a report—Alsos, CIOS, Theodore von Kármán's team, etc. Or maybe the Germans emptied out the factory and/or collapsed the entrances before the Americans arrived.

Perhaps the entrances were collapsed with V-4s still inside, just waiting for modern historians to rediscover them. Proof that Germany was building and even mass-producing manned spacecraft 20 years ahead of their time (even if they were never launched) would be incredible.

The two-man design also appears to demonstrate that Germany was really serious about delivering some sort of weapon of mass destruction over a long range. Electronic guidance systems were not yet reliable or accurate enough, so a pilot was necessary. With typical German thoroughness, the designers planned for two pilots instead of one, in case one pilot lost consciousness or changed his mind about going through with the mission after launch. I do not see why the Germans would have gone to such engineering extremes if the payload were not a weapon of mass destruction, or if the target were not at a longer range than the existing V-2 could reach accurately with an automated guidance system.

For what appears to be an early public report of the two-man rocket, see p. 5321.

For diagrams of the two-man rocket from an engineer who apparently worked on it, see pp. 5384–5388.]

Figure E.92: U.S. Army G-2 intelligence reports from 8 April 1945 describing a large underground factory in the vicinity of Neustadt an der Orla that had been using 20,000–30,000 French and other foreign workers for assembly line production of the “V4... two man rocket.” [NARA RG 407, Entry NM3-427, Box 11005, Folder 389-2.2 G-2 Jrnl File—89th Inf Div. 8–9 Apr 45]

A. W. Detweiler. V-2 Factory at Pössneck. 19 June 45 [AFHRA folder 519.650-1 Oct 1944–Dec 1945 Exploitation—Enemy Equipment; AFHRA A5729 frame 1573].

1. Following information phoned by Col. T. Ames, Asst. A-2, Air Staff Shaef:

a. The CIO (Group Capt. Humphrey) of 2nd TAF has been advised that the V-2 factory at Pössneck (J-73) has not been examined. Since this is in the Russian area, it is suggested by Group Capt. Humphrey that any action taken must be immediate.

b. Col. Hall, G-2 of the 30th Division, is reported to be familiar with this installation.

c. The above information furnished to 2nd TAF by a Major Darling.

d. It has been requested that Group Capt. Humphrey be advised of any action taken on the above.

[See document photo on p. 5375.

Pössneck and the rest of Thuringia were transferred from occupying U.S. forces to occupying Soviet forces on 1 July 1945, which prompted the urgency of this 19 June 45 memo.

This document proves that there was a rocket factory at Pössneck, which was only 13 km from Neustadt an der Orla, yet both are very far from Nordhausen and would not have been confused with the underground rocket factory there. The U.S. military used "V-2" in the generic sense to refer to large German rockets, so the Pössneck factory could have been manufacturing V-2/A-4 rockets or something else. Was the Pössneck factory the same as the "two-man rocket" factory? Perhaps the "Pössneck" factory was not actually in Pössneck, but was merely nearby, and the U.S. military referred to the nearest town of significant size, Pössneck. Or maybe the escaped prisoners were slightly off in their description of the location of the two-man rocket factory. Even if the Pössneck factory mentioned in the above document was a different facility, its existence demonstrates that that area contained underground rocket factories, making the reports of the two-man rocket factory highly plausible.

For examples of nuclear work that was conducted in this same area and same time, see:

> Rainer Karlsch. 2009. Wunderwaffen für den "Endsieg"? Die geheimen Arbeiten des Forschungsinstituts für Physik und dessen Verlagerung nach Neustadt an der Orla (1944–1945). *Zeitschrift für Thüringische Geschichte.* 63:259–276.

V-2 Factory at Possneck (J-73)

1. Intel Exec. 19 June 45

Ops

1. Following information phoned by Col. T. Ames, Asst. A-2, Air Staff Shaef:

a. The CIO (Group Capt. Humphrey) of 2nd TAF, has advised that the V-2 factory at Possneck (J-73) has not been examined. Since this is in the Russian area, it is suggested by Group Capt. Humphrey that any action taken must be immediate.

b. Col. Hall, G-2 of the 30th Division, is reported to be familiar with this installation.

c. The above information furnished to 2nd TAF by a Major Darling.

d. It has been requested that Group Capt. Humphrey be advised of any action taken on the above.

A. W. DETWEILER
Lt. Col., Air Corps
Executive

Figure E.93: This 19 June 45 U.S. intelligence memo proves that there was a factory making large rockets at or near Pössneck, 13 km from Neustadt an der Orla [AFHRA folder 519.650-1 Oct 1944–Dec 1945 Exploitation—Enemy Equipment; AFHRA A5729 frame 1573].

Hitler had a V-4 to raid London. *Daily Mail.* 18 April 1945 p. 4.

PARIS, Tuesday.

Hitler had another secret weapon—the V4—which he intended to rain on London, according to the Paris newspaper *Paris-Presse.*

But this last coup was prevented by the lightning Allied advance. A secret underground factory near Erfurt was captured and the secrets of the new weapon discovered.

The newspaper, from interviews with French deportees liberated from the factory, gives this picture of the new "V" weapon:

"Imagine a V2 which, instead of being blind and inaccurate, surpasses the accuracy of the most perfect artillery; a projectile 15 to 20 yards long, controlled by wireless from the ground, and travelling at a speed of some 3,750 miles an hour."

The subterranean factory, built in rock, was several storeys in height, with a network of tunnels and covering an area of about ten square miles.—*Reuter.*

[Tuesday was 17 April, so this *Daily Mail* story appears to have been written by someone in Paris with inside knowledge of the reporting before the *Paris-Presse* edition actually appeared in print on 18 April.]

Raymond Henry. Nous Font des Révélations sur le V-4: Dernier Rêve de Hitler. *Paris-Presse* No. 135, 18 April 1945 p. 1.

Libérés plus tôt que les Allemands ne pouvaient s'y attendre par l'avance americaine, des deportes français affectés à la fabrication des armes secrètes	Liberated earlier than the Germans could have expected by the American advance, French deportees assigned to the manufacture of secret weapons
nous font des révélations sur le V-4 dernier rêve de Hitler	we make revelations about the V-4 last dream of Hitler
Ces déportés qui n'avaient pas vu le jour depuis des mois, travaillaient au secret dans une usine souterraine s'étendant sur 24 km^2	These deportees, who had not seen daylight for months, worked secretly in an underground factory spread over 24 km^2
Hitler avait fait un rêve: le dernier. Il rêvait de gagner la guerre, grâce à une novelle arme secrète, le V-4. Ce rêve ne se réalisa pas. Les nazis n'en emporteront même pas le secret dans leur tombe. Car ils avaient eu l'imprudence d'affecter par représailles, aux usines où l'on expérimentait et fabriquait le V-4, des déportés français qui permettent aujourd'hui aux Alliés de percer le mystère de l'ultime arme secrète sur laquelle le III^{e} Reich fondait ses ultimes espoirs.	Hitler had a dream: the last. He dreamed of winning the war, thanks to a new secret weapon, the V-4. This dream did not come true. The Nazis will not even take the secret to their graves. For they had been imprudent enough to assign, by reprisals, to the factories where the V-4 was experimented with and manufactured, French deportees who now allow the Allies to pierce the mystery of the ultimate secret weapon on which the Third Reich founded its ultimate hopes.
Ces Français, qui ont travaillé pendant plusieurs mois sous terre, sans revoir la lumière du jour, ont pu fournir sur le V-4, ses perspectives et son emploi, des précisions que "Paris-presse" est le premier à publier.	These Frenchmen, who worked for several months underground, without seeing the light of day, were able to provide details on the V-4, its prospects and its use, which "Paris-press" is the first to publish.

[If this is the same massive underground V-4 rocket factory populated by French and other foreign workers and reported by Allied forces on pp. 5368–5373, its location was given there. Using the website tool http://www.echodelta.net/mbs/eng-translator.php, Modified British System coordinate [w]J869451 in the Nord de Guerre Grid corresponds to a location 1 km southeast of Dreitzsch, just east of Neustadt an der Orla. Thus the massive underground rocket factory described was not Nordhausen. It was approximately 110 km away from Nordhausen, and the description indicates it was much larger than Nordhausen.]

Nous connaissions les V-1 et les V-2. Nous connaissions même, par oui-dire, les V-3, qui devaient être une édition améliorée et agrandié des V-2.

Nous savions aussi que les Allemands se proposaient d'expédier une véritable pluie de ces projectiles sur Londres. Mais nul n'avait encore entendu parler des V-4, l'arme qui devait donner la victoire définitive à Hitler.

Cette arme était sur le point de sortir. Les usines où l'on procédait à la fabrication et aux essais viennent d'être conquises par les troupes alliées, au cours de leur foudroyante avance, et les secrets qu'elles ont révélés sont encore inédits.

C'étaient, dans la région d'Erfurt et pas très loin de ce sinistre camp de Buchenwald libéré, lui aussi, par l'offensive alliée, d'immenses, de prodigieuses usines souterraines enfouies les unes à côté des autres, étagées les unes au-dessus des autres, reliées par un labyrinthe de canalisations et de tunnels, et s'étendant sur une superficie de 24 kilomètres carrés. En bref, une gigantesque cité creusée dans le roc et où se succédaient interminablement, à la lumière de puissants globes électriques, ateliers, magasias, laboratoires et casemates.

Deux chemins de fer à voie étroite approvisionnaient ce royaume souterrain, deux chemins de fer si artistement camouflés que jamais l'aviation alliée ne les avait découverts.

We knew the V-1s and the V-2s. We even knew, by the way, the V-3s, which were to be an improved and enlarged version of the V-2s.

We also knew that the Germans intended to hasten a veritable rain of these projectiles on London. But no one had heard of the V-4, the weapon that was to give Hitler the final victory.

This weapon was about to be released. The factories in which it had been manufactured and tested have just been conquered by the allied troops during their tremendous advance, and the secrets they had revealed have not yet been published.

There were, in the region of Erfurt and not very far from the sinister camp of Buchenwald that was also liberated by the allied offensive, immense, prodigious underground factories buried one beside the others, levels ones above others, connected by a labyrinth of pipes and tunnels, and extending over an area of 24 square kilometers. In short, a gigantic city hollowed out of the rock with an interminable succession, lit by powerful electric globes, of workshops, storerooms, laboratories, and fortifications.

Two narrow-gauge railroads supplied this underground kingdom, two railways so artistically camouflaged that the allied aviation never discovered them.

[This article states that it was already known that V-3 (or at least one weapon system vying for that title) was an "improved and enlarged version of the V-2." This probably means that the standard V-2 length of 14 m was enlarged to 18 or 21 m long as reported elsewhere, accommodating more propellant and hence improving the rocket's range and/or payload capacity.]

Un projectile géant d’une précision absolue

C’est là, dans le mystère, que les meilleurs techniciens d’Allemagne, soumis à un étroit contrôle, préparaient le V-4. Le V-4? Imaginez un V-2, mais un V-2 qui, au lieu d’être aveugle et imprécis, aurait au contraire surpassé en précision les canons les plus perfectionnés; un projectile immense, long de 15 ou 20 mètres, propulsé par fusée, comme le V-2, mais pouvant, à la différence de celui-ci, être dirigé de terre par ondes hertziennes et capable, pendant tout le temps de sa course parcourue à une vitesse de 6.000 km à l’heure, d’indiquer sa position à la centrale de tir, grâce à des dispositifs gyroscopiques couplés avec un poste émetteur de T.S.F.; un engin enfin qui n’aurait peut-être pas pu changer le sort de la guerre, mai qui aurait certainement prolongé les hostilités en causant de nouveaux et incalculables ravages, et en provoquant pour les Alliés de graves difficultés supplémentaires.

Mais le danger est conjuré. Le V-4 git désormais, sans force et sans vertu, dans l’ombre de ces cavernes d’où les nazis aux abois n’ont pas eu le temps de le faire surgir. Quelques mois seulement, quelques semaines peut-être, paraît-il, nous séparaient encore du moment où ces monstres nouveaux se seraient abattus sur nous.

A giant projectile of absolute precision

It was there, in the mystery, that the best technicians of Germany, subject to a strict control, were preparing the V-4. The V-4? Imagine a V-2, but a V-2 which, instead of being blind and imprecise, would on the contrary surpass in precision the most perfect canons; an immense projectile, 15 or 20 meters long, propelled by rocket, like the V-2, but capable, unlike the latter, of being guided by Hertzian waves and capable, throughout all the time of its course traveling at a speed of 6,000 km per hour, of indicating its position to the launch station, thanks to gyroscopic devices coupled with a radio transmitter; a device which might not have been able to change the outcome of the war, but which would certainly have prolonged hostilities by causing new and incalculable havoc, and provoking serious difficulties for the Allies.

But danger is avoided. The V-4 lies henceforth, without force and without virtue, in the shadow of these caverns where the stymied Nazis did not have time to make it appear. Only a few months, perhaps a few weeks, it seems, still separated us from the moment when these new monsters would have fallen upon us.

[The V-4 weapon described above was a V-2 or A-4 rocket whose length had been increased from the usual 14 meters to “15 to 20 meters,” in order to carry more propellant and improve the rocket’s range and/or payload capacity. This V-4 was also described as having a much more precise guidance system (combining onboard inertial gyroscopes and external radio signals), which would have been especially important to achieve good targeting accuracy at ranges greater than that of the standard V-2 and/or for highly valuable payloads such as a nuclear bomb.

See also pp. 2938–2962.

If U.S. forces overran a factory that had been producing improved V-3 and V-4 rockets as described here, where is all the documentation for what was actually found and removed by the United States? Can that information be located in archives? Were prototypes of the rockets and the improved guidance systems brought back to the United States? If that material is still classified, can it be located and declassified now?]

Albert Ducrocq. 1947. *Les Armes Secrètes Allemandes.* Paris: Berger-Levrault. pp. 160–161.

On avait longtemps douté de l'efficacité militaire de la A-9: dépenser 100 tonnes de combustible et perdre une machinerie compliquée pour aller jeter seulement une tonne d'explosif sur le territoire américain, voilà qui semblait payer bien cher le plaisir d'ennuyer l'adversaire! Remarquons tout d'abord, à ce sujet, que le prix de revient n'est guère plus élevé que dans le cas d'un bombardement par V-2, puisque la fusée-mère A-10 est récupérable, et d'autre part, ce qui coûte cher (du moins en heures de travail englouties) ce n'est pas tant l'alcohol ou l'eau oxygénée que la machinerie des V-2 ou A-9; dans l'un et l'autre cas on en faisait le sacrafice à l'avance. [...]

Et puis il y a bien pire: dans l'esprit d'Hitler, la A-9 était aussi destinée, le cas échéant, à transporter des bombes atomiques sur le territoire américain. [...] Se rend-on compte des répercussions matérielles et morales du lancer d'une seule bombe atomique sur New-York par exemple! Il nous est pratiquement impossible de les mesurer.

D'ailleurs, outre le bombardement par A-9, les Allemands voulaient entreprendre le bombardement direct des côtes américaines au moyen de V-2 lancées par des sous-marins. C'était leur deuxième arme nouvelle contre l'Amérique. Elle devait entrer en action en même temps que la A-9, c'est-à-dire au début de l'été 1945...

There had long been doubts about the military effectiveness of the A-9: spending 100 tons of fuel and wasting complicated machinery to throw just one ton of explosive on American territory seemed like a high price to pay for the pleasure of annoying your adversary! First of all, it is worth noting that the actual cost is not much higher than in the case of a V-2 attack, since the A-10 first stage is recoverable, and second, what is expensive (at least in terms of man-hours) is not so much the alcohol or liquid oxygen as the V-2 or A-9 machinery; in both cases, the cost was decided in advance. [...]

And there is worse: in Hitler's mind, the A-9 was also intended, if need be, to transport atomic bombs onto American territory. [...] Do you realize the material and moral repercussions of dropping a single atomic bomb on New York, for example? It is virtually impossible to measure them.

What is more, in addition to A-9 bombing, the Germans wanted to undertake direct bombing of the American coastline using submarine-launched V-2s. This was their second new weapon against America. It was to come into action at the same time as the A-9, i.e. in early summer 1945...

[Albert Ducrocq (1921–2001) was a French scientist and science writer who was involved in the French investigations of German science and German scientists near the end of the war and after the war. He would have had considerable knowledge about German scientific plans and capabilities from his own investigations and also from former French (or other) workers that he had talked to.

His claims that German atomic bombs and delivery vehicles for them were ready or nearly ready by the end of the war agree with statements by many other independent sources.

According to Ducrocq, Germany had planned to launch a simultaneous attack on many Allied targets using its atomic bombs and different delivery vehicles for them. For independent confirmation, see pp. 4549–4550, 4587, 4621, 4627–4665, 4679–4681, 4766, 5038, 5454–5466.

For more information from Ducrocq, see pp. 5218, 5658–5659, 5666.]

Walter Dornberger. 1958. *V-2: The Nazi Rocket Weapon.* New York: Viking. pp. 138–140, 152, 236–237.

[pp. 138–140:] It was easy enough to see that the range of one-stage rockets, which had to go on carrying the useless deadweight of the empty tanks and heavy motors after the 'all-burnt', would never be appreciably increased. If we were going to add to the rocket's deadweight, already reduced to a minimum, any considerable load for long distances, even a change of propellants would be of very little use to us. The only exception would be a combination of hydrogen and oxygen with a theoretical exhaust velocity of over 10,000 feet per second. But this was for the time being out of the question because of the difficulty of handling liquid hydrogen. Nor would a bigger rocket help much. [...]

With an improved, lighter A4 type of one-stage rocket with relatively bigger tanks we might be able to achieve a range of 250 to 300 miles—but mainly at the expense of the warhead, that is, the payload.

We had to break new ground. Why need the rocket strike the ground at a speed of nearly 2,000 m.p.h.? If we gave it wings and took advantage of their lift, changing the trajectory to a glide after a suitable time interval, we could use the energy hitherto expended in making great holes in the ground to increase range.

Calculations showed that with such a structure we might achieve a range of 350 miles, which would be double that of the A4. [...]

Thus the A9 came into being.

Hundreds of calculations were made to plot the trajectory that would give the greatest range. Finally the missile was planned to reach, at a height of about 12 miles, a maximum speed of 2,800 m.p.h., and then go into a shallow curving glide with a peak of nearly 18 miles. On arrival over the target, at a height of about 3 miles, it was planned to fall perpendicularly, like the Fi 103 (V1).

It was only a step from the pilotless A9, with fully automatic guidance, to the piloted A9. This extremely fast aircraft, with a wing area of only about 145 square feet, had no military significance. Special landing flaps enabled it to land, after traveling about 400 miles in 17 minutes, at a speed of only 100 m.p.h.

This development of the A9, however, did not satisfy our ambitions. We wanted to cover thousands of miles. Our own private and exclusive sphere of activity began only beyond the extreme limit of the range of the heaviest aircraft.

Only by abandoning the one-stage for the multiple-stage rocket, that is, by dropping the dead weight when it had served its purpose and thereby improving the mass-ratio of the rocket, could we hope for these almost incredible range increases.

This was the origin of the A9/10 project. The object here was to cause the motors of the second stage (the A9) to begin firing only when the missile had reached a high speed by means of its first stage, which acted as a booster.

Catapulting was an alternative method of imparting a high starting speed to the A9. On the basis of calculations and experience with V1 launching sites, a long, inclined catapult had been designed capable of giving the A9 a launching speed of 800 m.p.h. This would have been sufficient for the fully fueled rocket to fly on smoothly, after leaving its launching ramp.

A better plan, however, and one which greatly improved range, was to construct the A10, weighing 87 tons and with a total propellant capacity of 62 tons, as the first stage of the combined A9/A10. The A9 was placed on top of the A10. The latter had a thrust of 200 tons for 50 to 60 seconds and gave the rocket a speed of 2,700 m.p.h. After exhaustion of the first stage the A9 would be ignited and lift out of the A10. The A9 was to tilt fairly sharply soon afterwards and reach a peak altitude of 35 miles. Then the long supersonic glide was to begin. Meanwhile the A10, equipped with brake-flaps and parachute, could be recovered for further use after drifting down on to water.

The A9, beginning to operate at a great height, would acquire an additional velocity of about 3,600 m.p.h., resulting in a maximal velocity of about 6,300 m.p.h. at the moment its motor cut off. A distance of 2,500 miles could therefore be covered in about 35 minutes. Like the single-stage A4 this two-stage rocket was to take off vertically and obviate the need for elaborate launching installations.

Countless trajectories were calculated by our outstanding expert in flight and ballistics, Dr. Steuding, and all of the factors involved, such as the earth's curvature and rotation, were taken into consideration. Guidance systems were investigated and development of the missile began.

For some months work on this project, which had been fully occupying large sections of our establishment, had ceased. I had forbidden further work on the plan in our practical branches, because of the urgency of the A4. Only the Projects Group was permitted to carry on.

During our frequent visits to this department we had repeatedly and thoroughly discussed these plans, due for practical development at an early date, as well as the optimal trajectory of the rocket. We had foreseen and planned for its use in time of peace. Very fast stratospheric rocket-aircraft, travelling at high supersonic speed, had reached design stage. They would be able to cross from Europe to America in 40 minutes.

Once we reached this stage the horses fairly bolted with us. With our big rocket motors and stage-rockets we could build space-ships which would circle the earth like artificial moons at a height of 300 miles and a speed of 18,000 m.p.h. Space stations and glass spheres containing the embalmed bodies of pioneers of rocket development and space travel could be sent round the Earth on endless journeys. Even an expedition to the moon was a popular topic.

We dreamed, too, of atomic energy, which would at last give us the necessary drive for flight into the infinity of pace, to the very stars. [...]

[p. 152:] I could not have been asleep long before I woke with a start.

Sssst—bang!

So Stölzel was doing his experimental firing after all.

Sssst—bang! Sssst—bang!

The window-panes rattled. Yet I had told Stölzel to set the time fuses so as not to disturb the peaceful slumbers of Peenemünde. [...] And I had given him permission to fire only 5 of the 15 rounds available. [...]

Something wrong there. That couldn't be Captain Stölzel, who had asked my permission that evening to carry out test firing during the night with his anti-dive-bomber tank weapon. It was not the 100 lb. high explosive charge of the 10-inch solid-propellant rocket which had awakened me from my first deep slumber and set the windows of my room rattling. [...]

Peenemünde was being raided! [...]

[pp. 236–237:] The demand from increased range made it necessary to start work again without delay on the winged A4, which had been lying fallow since spring 1943. We had named the winged A4 missile the A9. Ever since the beginning of the war we had seen that we could not tackle the A9 at Peenemünde as well as the A4 with any hope of its becoming operational before the end. The problems would have made far too many demands on our depleted staff. Some research had, however, been done in the wind tunnel since the spring of 1940 to determine the proper form of the supersonic wings and tail unit of the A9. The findings were now hastily dug out again and a schedule of tests drawn up.

On 8th January, 1945, the first A9 was launched. The control failed about 100 feet above the firing table. A few days later we were unable to launch a new projectile because the alcohol tank had developed a leak. At last, on the 24th, we had our first success. The rocket, climbing vertically, reached a peak height of nearly 50 miles at a maximum speed of 2,700 m.p.h. This purely rocket-powered aircraft, with a wing area of 145.32 square feet, broke the sound barrier without trouble. It flew with stability and steered automatically at both sub- and supersonic speeds. On the descending part of the trajectory, soon after the rocket levelled out at the upper limit of the atmosphere and began to glide, a wing broke. On the whole the result was eminently satisfactory and more than fulfilled our expectations.

Thus our theories on this design had been borne out as well. It was possible to cause rocket aircraft to fly at many times the speed of sound, and they could certainly be landed by means of braking and landing flaps. We were well on the way to solving a problem which, together with high-altitude research, was the first I had set myself to tackle after the war: the landing after a flight into airless space. We had taken a long stride forward in developing the first intermediate stage preceding the space-ship. Rocket aircraft could cover long distances in the upper stratosphere, at heights of 12–16 miles, at incredible speed and land in safety. If only we could succeed in maintaining full rocket thrust just long enough to ensure that we reached this height at very high supersonic speed, flying horizontally and in the right direction, and then either went into a glide or could switch in a low-thrust cruising motor using very little propellant, why, then we should be able to bridge thousands of miles by strictly economic means. Such were the ideas that occupied our minds in 1944. If we could realize them in practice we might hope to enrich international traffic, a few years after the war, with newer and bigger models. This revolutionary form of transport could never be rivalled for speed and range by normal propeller or jet-driven aircraft.

Basically the problem had already ceased to be a problem. It was only a question of working out the technicalities and devoting enough time to development. But the evacuation of Peenemünde put a stop to all further experiment.

[Dr.-Ing. Hermann Steuding was the main group leader for evaluation in the control and flight technology department BSM / A I (StF) in Peenemünde.]

[The raid was the Operation Hydra bombing attack on Peenemünde by the British Royal Air Force during the night of 17–18 August 1943.]

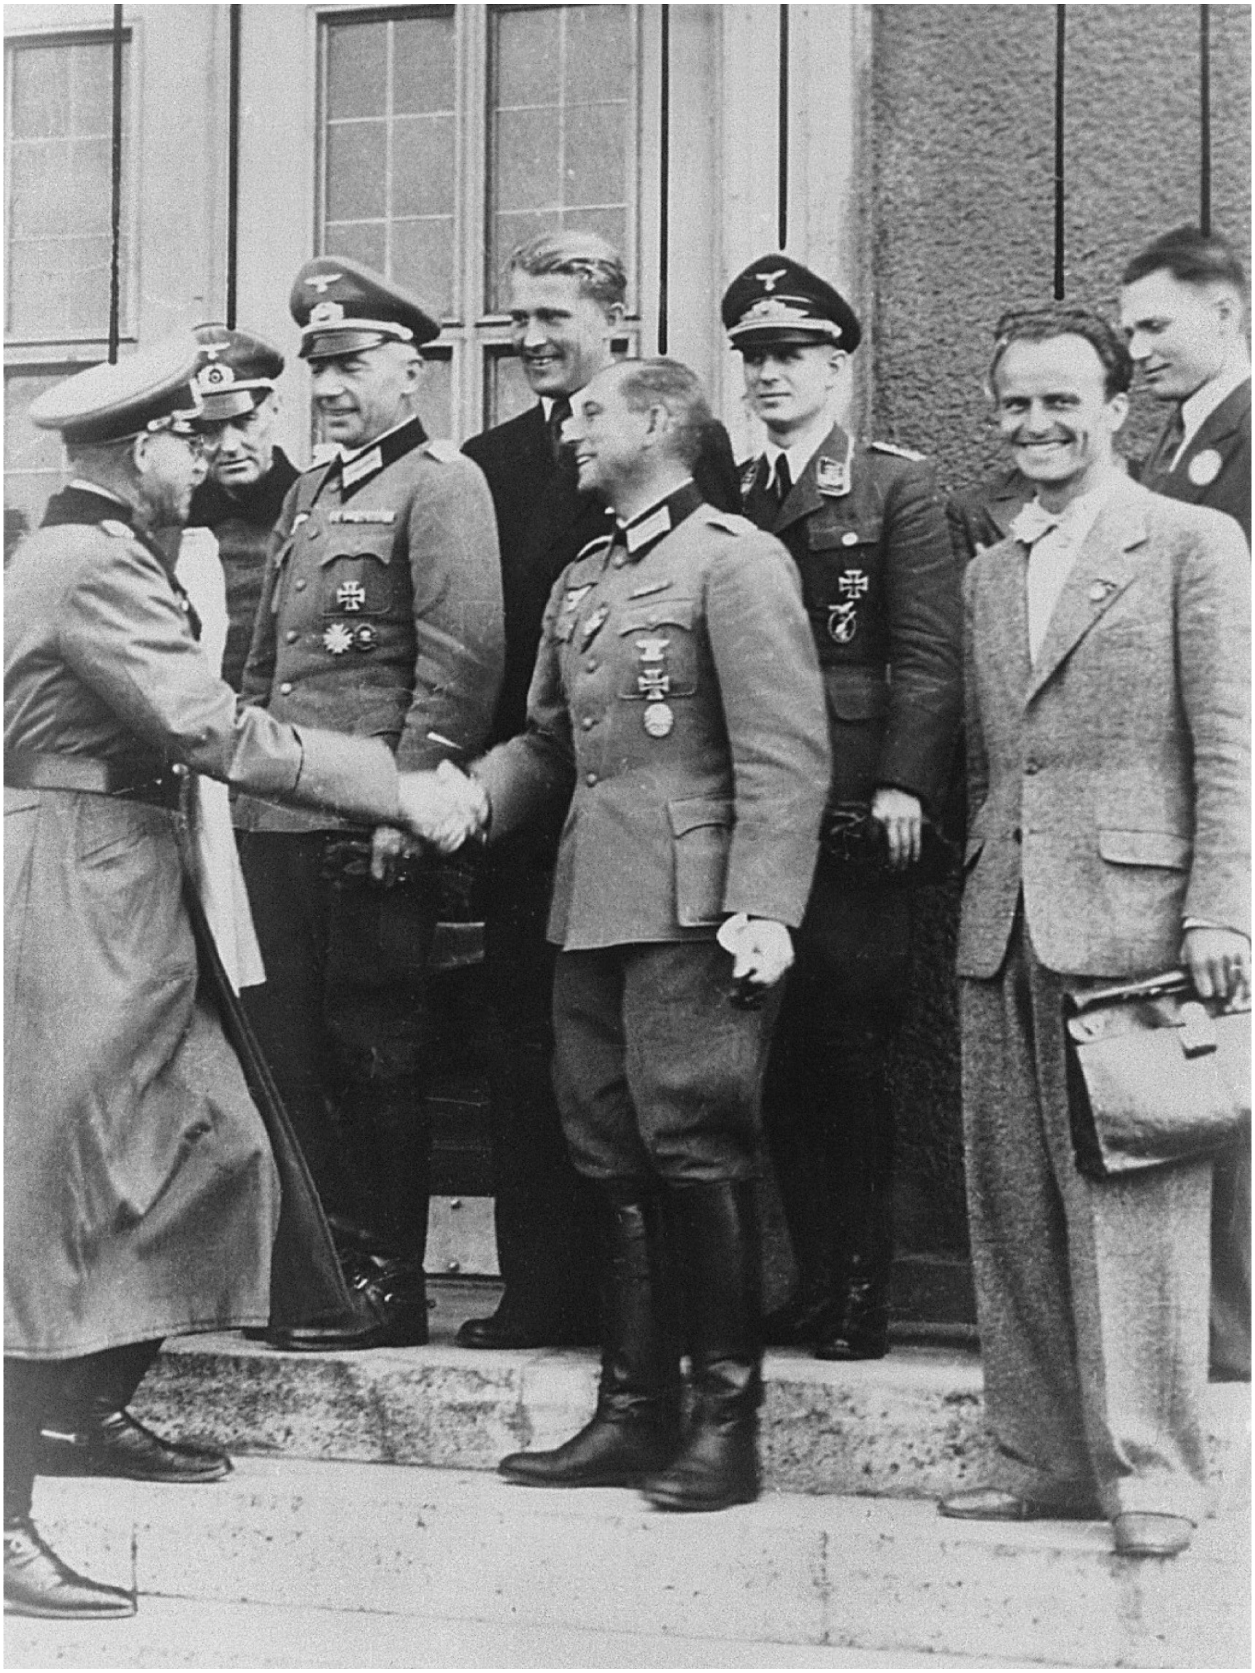

Figure E.94: Recognition for the first successful flight of the A-4/V-2 rocket on 3 October 1942, including Dr. Wernher von Braun (darkest civilian suit), Captain Heinz Stoelzel (young man in dark uniform standing to the right of von Braun as seen from our perspective), and General Walter Dornberger (in front of von Braun, wearing a hat).

CIOS ER 38. *Luftschiffbau Zeppelin—Dir. Eckener.* 25 May 1945. [See also p. 5327.]

[...] DIR. KURT ECKENER was interviewed and gave information:- Luftschiffbau Zeppelin made only the A and B tanks for the A-4, eastings thereto and part of the outer case. The threefold tube casting caused trouble owing to leaks developing.

The tanks were developed by L. Z. who also helped other firms to go into production. One of the main of these firms was Schindler of Kennelbach, Austria, Nr. Bragenz where tanks can probably be found now. DR. VON BRAUN was the Peenemünde representative with whom this firm carried out the development; he gave them an order for tanks of the same diameter but about 20 cm. longer than normal, and about ten of these were made. Some of these should also be available at Kennelbach. In full production 200 pr. of tanks were produced, and 350 bodies. At first they were despatched assembled (but later not) to Mittleberg (werk?) in Harz.

Leichtmetall-Regensburg, Meldewerke-Slesian, Marcus-Berlin also made tanks. The only special tool involved was a welder used on the tanks which is available at the works. All the documents were removed by the French. Herr Zalewski-Neurenborn could give more detail on the tanks and construction. Venturis, Eckener said, were made by Linke-Hoffmann.

The only development of A4 of which Eckener had heard was one of the same size with lateral wings [A-9 or A-4b] which was to have a range of 10,000 Km. and a ht. [maximum altitude] of 60 Km [on an A-10]. One of these had been constructed at Peenemünde. It is possible that this might have been flown by a pilot. One of Eckener's test pilots was exceedingly keen to fly an A4 and had asked him to approach von Braun to suggest this. One of his test pilots had been killed previously flying a V-1. [...]

ZALEWSKI, when interviewed, gave information:-
L. Z. produced only the middle part of the rocket i.e. the tanks and surrounding body. Components to the rear (mainly of ferrous composition) were produced by Linke-Hoffmann of Breslau. Turbines were produced by Walther-Kiel who also with Siemens produced electrical apparatus. [...]

He named ten firms engaged on production of tanks. They were:-

(1) L. Z.—Friedrichshafen.

(2) Austria—Vienna.

(3) Bertram Müller—Weidenein.

(4) Wezel—Uhingen, Nr. Stuttgart.

(5) Marcus—Berlin.

(6) Melder—Freistadt i/e S.

(7) Metallbad—Halberstadt.

(8) Gebrüder Hermann—Köln.

(9) Mittelwerke—Halle.

(10) Schindler—Kennelbach, an associated firm.

Swiss Turning a Deaf Ear to Stories of Nazi Infiltration. *The Swiss Observer* (Journal of the Federation of Swiss Societies in the U.K.) 31 January 1947. [https://doi.org/10.5169/seals-686905]

Reprinted from "New York Herald Tribune."

[...] There has been a great outcry in Switzerland also over the immigration of Captain Heinz Stoelzel, once liaison officer between the army and the German scientists who were working in research laboratories at Peenemünde where the V-2 rockets were developed. Stoelzel is known to be an unrepentant German, and proud of his nation, however he may feel about Nazism. When he arrived in the country last summer he was invited to lecture before the Swiss Federal Institute of Technology.

In his lecture he asserted that Germany was well on its way to perfecting the atomic bomb and then aroused some popular wrath by crying: "Thank God, the Allies did not seriously damage Peenemünde. German research will always continue, and in years to come will make important contributions to science, just as in years gone by." [...]

Cables from the files of Leslie Groves. [NARA RG 77, Entry UD-22A, Box 160, Folder In & Out July 16, 1946–Jan. 1947]

From: Bern Switzerland sgd Harrison

To: State Department

Nr: A 433 23 September 1946

Reference is made to the Legation's confidential airgram No. A-423 to the Department of September 11, 1946, copy of which was sent to Berlin, with respect to the German military internee, Heinz Stoelzel, presumed to be identical with the German national of the same name who delivered a lecture at the Swiss Federal Technical Institute at Zurich on V-2 bomb production as reported in the Legation's restricted airgram A-385 of August 19, copy of which was forwarded to Berlin.

As a result of investigations conducted by Mr. Leonard L. Bacon of the American Consulate General, Zurich, it has now been definitively ascertained that the Legation's presumption as to the identity of Heinz Stoelzel is correct. The Consulate General reports that it has interviewed Mr. Pierre Schwaar, the author of the Die Nation article quoted in the Legation's A-385 and that Mr. Schwaar, who attended Stoelzel's lecture, states that it was conducted under the auspices of the Swiss Federal Technical Institute's School of Aerodynamics. Stoelzel was introduced by Dr. J. Ackeret, Head of the School, with the preface that Stoelzel "was a German scientist with practical experience in his speciality of rocket projectiles". The Consulate General conveys Schwaar's impression that Stoelzel treated the subject in a superficial and "popular" manner; that most of his information appeared to come chiefly from American popular magazines; and that Stoelzel endeavored to give the impression that whereas the atom bomb was all very well as a military weapon, the Germans had developed a principle of application of energy which had immediate peacetime uses.

The Consulate General further reports that it has succeeded in obtaining the following highly confidential information from the office of the Zurich Cantonal Fremdpolizei:

"According to the police file, Stoelzel was born on February 2, 1916, in Germany; birthplace and residence unknown. He was a captain in the Wehrmacht and assigned to the rocket-bomb plant at Peenemünde, at an unknown date he came into Switzerland as a deserter and was interned. In March 1946 he was reclassified as a refugee after examination by the Bundespolizei in pursuance of the general policy of transferring military internees from Army control to police supervision. He was then granted a "Studiumbewilligung" or study permit at the Swiss Federal Technical Institute as an expert on rocket projectiles and took up residence in Zurich at 25 Rosslistrasse. The Kantonal Fremdenpolizei received in August of this year from the Police Division of the Federal Justice and Police Department at Bern a letter stating that Stoelzel was to be repatriated to Germany 'immediately'. This has not yet occurred. The Fremdenpolizei had a copy of Stoelzel's lecture and apparently took an interest in his point of view.

The Legation proposes, through the medium of the American representative on the Joint Allied-Swiss Commission established under the Washington Accord, to present Stoelzel's name as a candidate for repatriation by the Swiss Government. In the event that the Swiss Government agrees to this suggestion, the Legation will, if possible, notify promptly the appropriate authorities in Germany in order that a carefully kept supervision of him there may be effected.

With respect to Stoelzel's associates, Lt. Kunick and Capt. Riedl, referred to in the SSU, Bern, report quoted in the Legation's A-423, the Military Attaché has made available to the Counselor of Legation for Economic Affairs copies of reports prepared by his office on April 4 and April 17, 1946. These reports indicate that Riedl vanished from the internment camp at Weesen and presently is living with his American wife at Ascona. Kunick, although nominally still interned at Weesen, makes frequent trips to Zurich where he is seeking employment.

The Legation will continue to report such additional information with respect to these 3 cases as may come to hand.

[...] INFO: AAF, ASW, CAD, P&O, R&D, Gen Groves, [...]

From: Bern Switzerland sgd Harrison

To: Secretary of State

Nr: A 468 16 October 1946

Reference is made to the Legation's secret airgram No. A-433 of September 23, 1946 to the Department, copy of which was forwarded to Berlin, with respect to the German military internee Heinz Stoelzel.

In accordance with the proposal outlined in the reference airgram, the American member of the Joint Allied Swiss Commission has inquired on behalf of all Allied members the position of the Swiss Government with respect to the freedom accorded Stoelzel and other German military internees and the likelihood of his and their repatriation. This request was made at the October 3 meeting of the said Commission. No response thus far has been made by the Swiss member.

The Department will have noted the allusion in the reference airgram to Professor J. Ackeret, Head of the Swiss Federal Institute's School of Aerodynamics, who introduced Stoelzel at the latter's lecture at Zurich on June 28, 1946. The Consulate General at Zurich has indicated its intention to make further inquiries with respect to Professor Ackeret. The Legation has noted that Professor Ackeret's name is No. one on the list of "Suggested Repatriations from Switzerland" dated August 19, 1946, prepared by the Department's Division of Economic Security Controls, recently transmitted to this Legation. Such a listing would suggest that the Department regards Professor Ackeret as a German national. The Legation's information, however, indicates that he is a Swiss national. In this connection, the Legation quotes herewith the following report submitted to the Counselor of Legation for Economic Affairs under date of October 14, 1946 by local office of SSU:

"According to our information Ackeret is a Swiss national but very pro-German and was pro-Nazi. He is the co-inventor of the experimental Ackeret-Keller internal combustion turbine. In conjunction with Keller who is completely under his influence, Ackeret was trying to form a Swiss cooperative research group to work on jet propulsion aircraft. It is believed that this is being done with an eye to future cooperation with Germany because other projects of more immediate profit were being shelved in favor of a scheme which will, at best, not be profitable for years."

"The above information is dated May 1945."

The comments of the Consulate General at Zurich with respect to Professor Ackeret will be transmitted to the Department upon receipt.

[...] INFO: AAF, ASW, CAD, P&O, R&D, Gen Groves [...]

[The *Swiss Observer* and *New York Herald Tribune* reported that Heinz Stoelzel "asserted that Germany was well on its way to perfecting the atomic bomb." What information did Stoelzel have about the German atomic bomb? Did his knowledge come from the fact that he was developing intercontinental rockets to carry such a bomb?

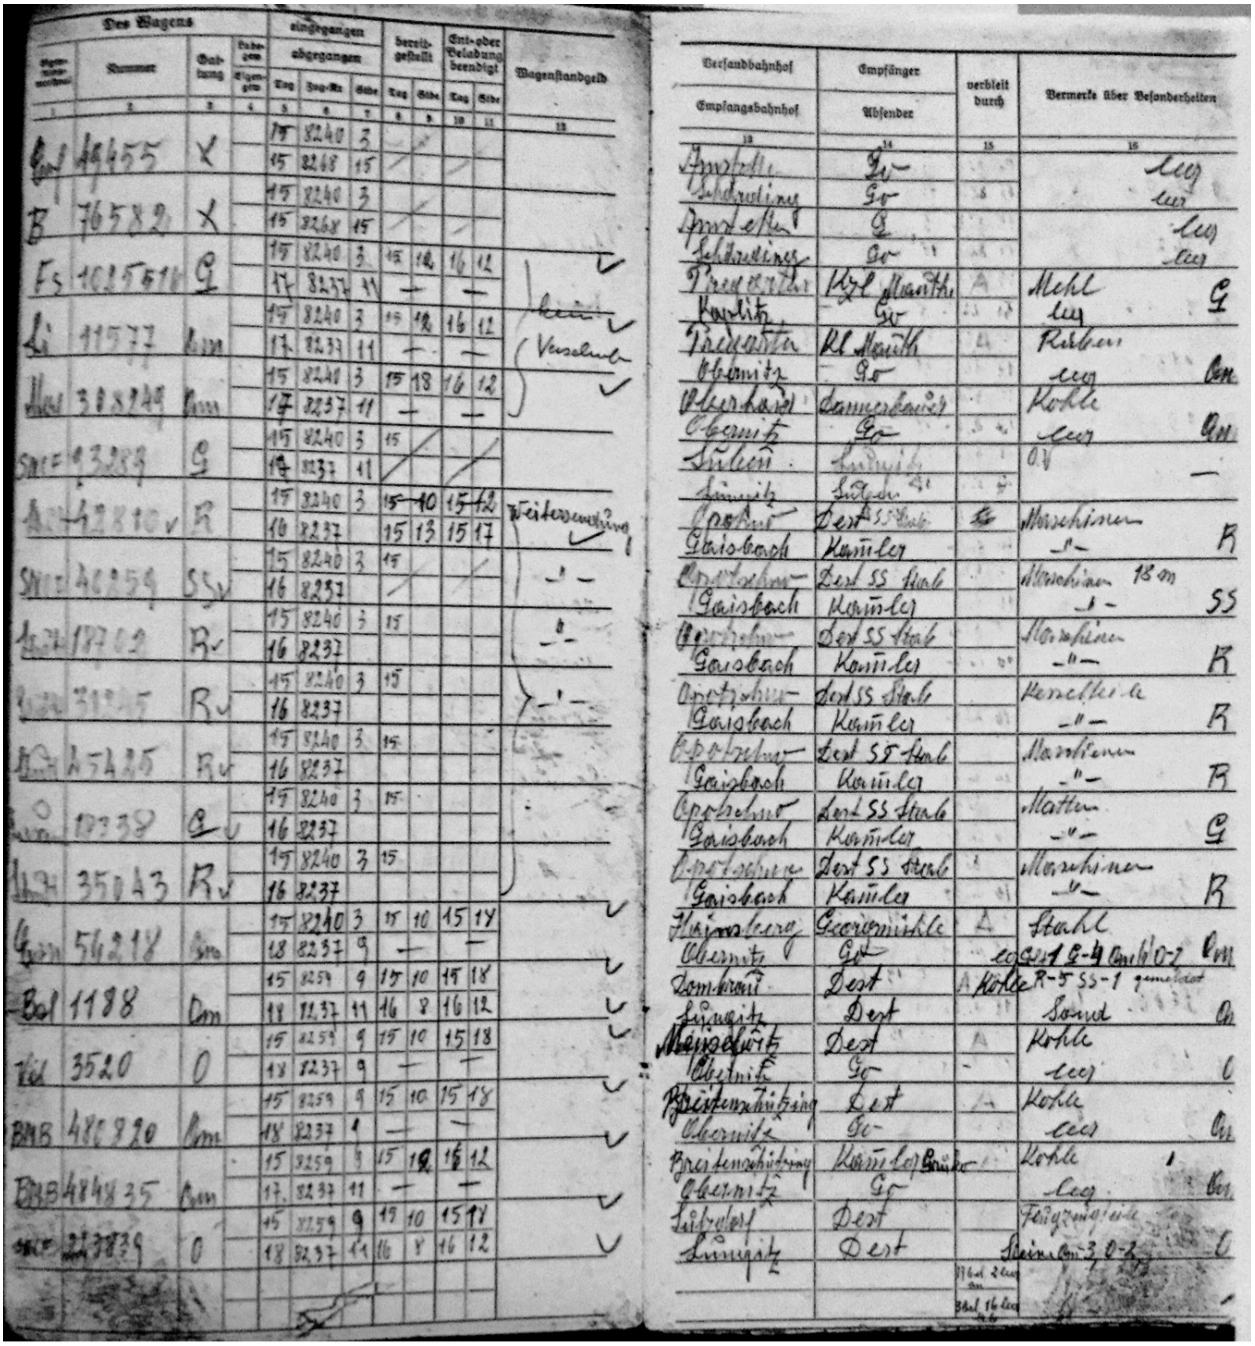
Why was this information on Stoelzel sent directly to the attention of Leslie Groves, where it remains in his files at the U.S. National Archives and Records Administration? Does this incident suggest that Groves knew that there had actually been a German atomic bomb project, and was taking action behind the scenes to ensure that no one (even a lone refugee in Switzerland) spoke out about it?

Essentially all of the other scientists who had been involved in wartime German programs to develop and deliver weapons of mass destruction were employed by and under the tight control of various Allied governments, either in those Allied countries or in Allied-occupied zones of Germany and Austria. Among the knowledgeable alumni of those wartime German programs, Heinz Stoelzel was virtually alone in being free of Allied employment, free of living in an Allied country or an Allied-occupied country, and free to publicly reveal the true facts about how far those wartime programs had progressed. Thus Groves and other high-ranking Allied officials who were aware of the wartime German programs would have viewed Stoelzel as a unique threat.

Note the line in the 23 September 1946 cable: "in order that a carefully kept supervision of him there may be effected." After this incident, Stoelzel did indeed return to Germany, where he apparently kept a very low profile for the rest of his life. His silence from then on may have been enforced by government minders and censors, or it may have been self-imposed to avoid the likely unpleasant consequences.

A corollary to this discussion is that all of the German and Austrian scientists working for Allied countries (or under Allied scrutiny in Germany and Austria) would have been censored by the same sort of "carefully kept supervision" of their public statements for the rest of their lives. Thus it is no surprise that they made so few comments (only the occasional slips) for the rest of their lives about how far the wartime German programs had progressed.

The statements of U.S. officials in these documents do not seem to reflect favorably on them when viewed by a modern reader. Jakob Ackeret (1898–1981) was a Swiss citizen, born in Zurich, and a famous professor of aerodynamics who had been teaching at the university in Zurich since 1931. Despite those facts, U.S. officials claimed that he was a German citizen and made him priority number one on their list of people that the United States was ordering Switzerland to deport to Germany, from whence presumably the United States itself would seize him (and his research). It seems as if the most damning evidence that U.S. officials could cite against Professor Ackeret was that he passed up "other projects of more immediate profit" because he was more interested in working on a much more innovative research "scheme which will, at best, not be profitable for years." Apparently the U.S. officials could not even imagine why someone might prefer to pursue long-term innovative research over short-term non-innovative commercial profit, and were convinced that must mean that Ackeret was part of an evil conspiracy. How common was this mindset?]



A train shipment of "18 m machines" and accessories was apparently personally forwarded by Hans Kammler in St. Georgen an der Gusen, Austria on 15–16 March 1945

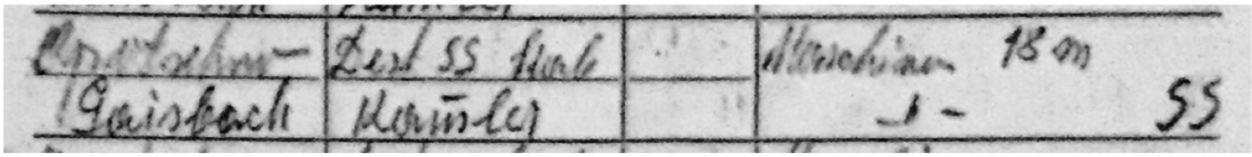


Figure E.102: A shipment of "18 m machines" and accessories was sent by train to the SS staff leadership at DEST (St. Georgen an der Gusen) on 16 March 1945, and apparently personally forwarded by Hans Kammler from there to Gaisbach, Austria on 16 March 1945, as indicated by a logbook of train shipments [Collection Rudolf A. Haunschmied, from St. Georgen an der Gusen train station]. Could these high-priority 18-meter-long machines have been advanced rockets?

Charles R. Christensen. 2002. *A History of the Development of Technical Intelligence in the Air Force, 1917-1945: Operation Lusty.* Edwin Mellan Press. p. 189

Dr. A. Pohlhausen from the Peenemunde Group assisted Northrop Aircraft Company with guidance system for their missile development program. Pohlhausen had worked out the mathematical formula for the motion of a gyroscope under high G-forces. His work was being used to develop a guidance system for the transoceanic A-10 surface-to-surface missile when the war ended.

[See also pp. 2938–2962.

Dr. A. Pohlhausen appears to be Dr. Karl Pohlhausen. For biographical information that is remarkably silent on his wartime work, apart from confirming that his first postwar work was on guidance systems, see: https://www.annualreviews.org/doi/pdf/10.1146/annurev.fl.16.010184.000245

Christensen also cited AFHRA documents [Christensen 2002, pp. 198–199]:

Colonel H. M. McCoy to Commanding General, AAF, Subject: "Effect of Possibly Reduced Funds for Project PAPERCLIP." Letter with Exhibits "A"–"H" dated 12 June 1947 in Air Materiel Command (AMC) History Office. "History of AAF Participation in Project PAPERCLIP, vols. I and II" May 1945–August 1948, dated August 1948, Air Force Materiel Command History Office (AFMC/HO), Boxes 340 and 341, Loose Files attached to reports.

Christensen notes: "McCoy's June 1947 letter with annexes is a full accounting of the support provided to the Air Force from German scientists. Annex 'B,' which is 29 pages long, provides a detailed summary of support given to jet, guided missile, materials, electronics, and aeromedical research by scientific specialists."]

Winston Churchill. 13 May 1945. BBC London.
[https://www.ibiblio.org/pha/policy/1945/1945-05-13a.html]

There was one final danger from which the collapse of Germany has saved us. In London and the south eastern counties we have suffered for a year from various forms of flying-bombs—perhaps you have heard about this—and rockets, and our Air Force and our ack-ack batteries have done wonders against them. In particular the Air Force turned on in good time on what then seemed very slight and doubtful evidence, hampered and vastly delayed all German preparations. But it was only when our Armies cleaned up the coast and overran all the points of discharge, and when the Americans captured vast stores of rockets of all kinds near Leipzig, which only the other day added to the information we had, and when all the preparations being made on the coasts of France and Holland could be examined in detail, in scientific detail, that we knew how grave had been the peril, not only from rockets and flying-bombs but from multiple long range artillery which was being prepared against London. Only just in time did the Allied armies blast the viper in his nest. Otherwise the autumn of 1944, to say nothing of 1945, might well have seen London as shattered as Berlin.

For the same period the Germans had prepared a new U-boat fleet and novel tactics which, though we should have eventually destroyed them, might well have carried anti-U-boat warfare back to the high peak days of 1942. Therefore we must rejoice and give thanks, not only for our preservation when we were all alone, but for our timely deliverance from new suffering, new perils not easily to be measured.

Ernst Krause. Interviewed by David DeVorkin. 10 August 1982.
[https://www.aip.org/history-programs/niels-bohr-library/oral-histories/28022]

DeVorkin: Okay. We're talking about a period that already brings us up into '44 and '45, and I don't want to leave the war years certainly without talking about your second tour to Europe and your interrogation of German scientists. Is this an appropriate time to find out, (a), how you got into it, and (b), what transpired?

Krause: All right. It's a good point in time, yes. What had happened toward the end of the war, and we're now in something like early 1945, spring [...] We went to Garmish Partenkirchen. In fact, we were in Paris, at which point I was joined by a Navy Intelligence officer from ONI, and he and I drove a jeep from Paris to Munich. I was part of the R. Porter group which had been constituted by the Army. Porter was from General Electric and had been working on some Army programs. [...]

In any case, when we went to interview the German technical people in Garmish, the incident that is of interest here is the fact that the intelligence officer said, "Now, don't you technical fellows start talking. We have to soften these people up first. We have experience in this, and let us get them softened up first and then they'll start talking. They won't want to talk initially." We agreed. Our first interview was with three of the Germans, two of whom were technical people. As soon as these three Germans sat down and we sat down at the table, the Germans began talking and talking and talking about what they had developed, what further advances they had on the drawing board, what they could do with the V-2 to improve it, to expand it, to extend its range, to improve its guidance accuracy—all of these things they had worked out in great detail, and they wanted to tell us about it.

DeVorkin: They were not speaking through a translator? You knew German well enough?

Krause: I knew German well enough. We did have a translator present. I understood German well enough so that I didn't really need the translation. In any case, the discussion went on and on. Pretty soon they pointed out that they had on the drawing boards the complete analysis and design for a V-2 which would extend its range to 3000 miles, which I think they called the V-2 A or B.

DeVorkin: The Wasserfall?

Krause: The Wasserfall was one of the German missiles, but as I recall, was not one of the V-2 long range variants. They stated that one of the V-2 design variants included small wings to provide aerodynamic glide on re-entry which would extend its range to 3000 or more miles. With this design it would be possible to set up a launch site somewhere in the state of Washington, and bomb Tokyo.

DeVorkin: That, I didn't know.

Krause: They argued that if only the Americans would now get behind us, and take them, the group, to the U.S., they could set this up in so many days, (they'd worked it all out), and they'd bomb Tokyo.

[Although Krause's memory of details is fuzzy after nearly 40 years, his description of the 3000-mile rocket agrees well with archival documents: a V-2 variant with wings, a longer range, and the letters "A" and "B" in the name (A-4b); the 3000-mile range (if used on an A-10 first stage, which was frequently assumed without being explicitly stated in documents); German experts who believed that goal was very close to being achieved; Allied officials who wanted to use as much German technology as possible against Japan in the time between V-E Day and V-J Day; etc.

One key point from this interview is that the German experts proposed to set up a 3000-mile-range rocket "in so many days" so that the United States could quickly bomb Tokyo. That demonstrates that such long-range rockets were already at a highly advanced stage of development (contradicting Krause's claim elsewhere that they were only "on the drawing board").

Another key point is that both the Germans and the Allies involved in Krause's circa May 1945 discussion would have known that the only way it would be even remotely attractive to build and launch a long-range rocket at Tokyo is if the rocket had a nuclear payload. (U.S. planes were already dropping lots of conventional bombs on Japan—why deliver one more the hard way?) The Allied officials in that discussion likely did not know that the United States would soon have its first fission bombs, and they certainly would not have told the Germans. These German engineers would not have known about the Manhattan Project from any other sources. So if the German engineers and the Allied representatives they were talking to were thinking about a nuclear weapon available for near-term use against Tokyo, they would have been thinking about a German nuclear weapon, and one already specifically designed to mount on a rocket.]

LARGE-SCALE PRODUCTION OF V-2 BOMBS NEAR WHEN GERMANY SURRENDERED

HEADQUARTERS, COM Z - Mass production of the V-2 rocket bombs, capable of pin-point bombing at a range of 3000 miles, was within reach of German scientists at the close of the war, U.S. Army Ordnance intelligence experts revealed today. Within six months after VE-Day, they said, Germany would have been able to produce the bomb on a mass scale, and the Germans believed they would have turned them out in large enough numbers to "neutralize any advantage our airplane superiority had given us".

The intelligence experts based their findings on a month-long survey of the huge rocket assembly plant and in conversations with captured scientists. The plant was built 800 feet deep in the heart of the Kohnstein mountains near Nordhausen, Germany. It was captured by units of the U.S. First Army in the closing days of the war.

Major William J. Bromley, of Grants Pass, Oregon, who directed the job of assembling 100 of the projectiles for delivery to the United States for analysis, disclosed that numerous gadgets and improvements, designed to give the rocket greater range and accuracy, were much in evidence at the factory.

"That raid on the experimental plant at Peenemunde on the Baltic by British planes set the scientists back just about six months in their experiments," Major Bromley said. "They admitted that it caused great damage to installations, and killed 800 of their best authorities. That raid was a life-saver for us."

A bit reluctant to talk at first, the scientists, most of whom are between 25 and 35 years of age, went on to relate other plans in which they displayed blue prints for a proposed V-bomb intended to fly 3,000 miles. It obviously was designed as a threat to American cities and industry, but never got beyond the blue print stage.

Maj. Bromley related that they felt that in two years' time they could develop rockets that could be shot from the British Isles to Japan -- a distance of 15,000 miles. They admitted, however, that this was strictly theoretical.

In the plant there was visible evidence of the proposed V-bomb campaign. Completely bomb free, it was located some 800 feet from the surface in the side of a limestone mountain, and was reputed to be the largest underground factory in the world.

Two large tunnels were separated by a network of smaller tunnels, through which a 25-mile railroad ran to form an assembly line capable of turning out 900 V-2 bombs a month in addition to other V-weapons and airplane motors. Sabotage by the 12,000 slave laborers and lack of materials, however, kept the figure actually well below that.

Maj. Bromley was assisted in his task of gathering together the parts for the 100 V-weapons by the 144th Motor Vehicle Assembly Company and other Ordnance Intelligence units. The missiles are being shipped to the United States, where they will be subjected to thorough study and experiments by the nation's leading scientists at the Army's huge testing area at Aberdeen Proving Ground, Maryland.

Gladwin Hill. New York Escaped V-2 Rockets By a 6-Month Margin, Army Says. ***New York Times.*** **14 June 1945 pp. 1, 5.**

PARIS, June 13—The Germans had planned to bomb the United States with V-2 rocket projectiles like those that crashed into London and might have succeeded by November, United States Army Ordnance experts reported today.

German scientists reached the blueprint stage in producing a 3,000-mile bomb that they believed would be accurate enough in destruction to offset our advantage in air power, which was a crucial factor in the Allied victory.

The six-month margin of safety represented by the time between V-E Day and November was provided by the RAF attack on the Germans' experimental plant at Peenemuende on the Baltic two years ago. The Germans said it killed 800 of their leading experts and set their work back six months.

This was the Allies' third escape from big Nazi schemes of destruction which the conquest of the Germans has disclosed.

The Germans had a system of V-1 bases in northwestern Europe that would have demolished London if it had not been disrupted by American bombing. They also had expected within a few months to perfect a bomber capable of attacking New York from Europe.

Purely on the basis of theoretical work, the Germans figured that in two years they could produce a rocket bomb that would go from the British Isles to Japan—15,000 miles—Maj. William Bromley reported.

The Germans' plans were learned during a five-month investigation of an amazing rocket assembly plant 800 feet underground in the Kohnstein Mountains near Nordhausen, Germany, which had 12,000 slave workers, many of them from the odious Nordhausen concentration camp. Sabotage by them, along with a shortage of materials, was credited with keeping production far below the capacity of 900 V-2's monthly, in addition to some V-1's and airplane engines.

The plant, burrowed out of limestone, was composed of two large tunnels connected by a network of smaller ones, with a twenty-five-mile railroad running through them.

The German scientists who described their work were mostly only 25 to 35 years old. One hundred of the V-2's have been assembled and are being shipped to the United States. They will be studied at the Army's Aberdeen Proving Grounds.

[For other newspaper articles based on the same 13 June 1945 press release by the U.S. Army, see:

> V2s with Range of 3,000 Miles: Would Have Been Ready by VE-Day. *Daily Mail* 14 June 1945 p. 1.
>
> "V2" with Range of 3,000 Miles If War Had Gone On. *Manchester Guardian* 14 June 1945 p. 5.
>
> V-2s, to Reach America, Were Nearly Ready. *Daily Worker* (London) 14 June 1945 p. 4.
>
> 6 Months, Foe Might Have "Veed" Toronto. *Toronto Daily Star* 14 June 1945 p. 2.

Construction of standard A-4 or V-2 rockets with a maximum range of approximately 350 km (approximately 200 miles) was ordered in 1939 and pursued with large amounts of funding and personnel for several years before mass-produced A-4 rockets could finally be used militarily starting on 8 September 1944.

This report (based on detailed on-site inspections of German rocket programs) and numerous other Allied and German sources in this appendix (e.g., pp. 5206–5208, 5337–5341, 5352, 5355–5359, 5365, 5398, 5429, 5441–5444, 5452–5455, 5465–5466, 5472, 5479–5490, and 5532) made it clear that mass-produced (not even just prototype) intercontinental rockets with a range roughly 15 times greater than that of the standard A-4 would have been ready by early November 1945, or even sooner without Allied bombing.

Publicly released postwar Allied reports and published history books also claimed that such intercontinental rockets never progressed beyond the paper design phase [e.g., Neufeld 1995, p. 283]. Given that it took over five years from the paper design of the A-4 to the first military use of mass-produced A-4 rockets, well-informed Allied inspectors and German officials could not possibly have expected a far more advanced rocket with 15 times greater range to make the leap from paper design to mass-produced deployed weapon in just six months.

The most plausible explanation for the apparent paradox is that Allied inspectors discovered well advanced hardware development, testing, and/or production programs for intercontinental rockets, but were censored from publicly revealing knowledge of anything more than paper designs.

Indeed, the press release on p. 5402 explicitly indicated that it was censored. Somewhere there must have been (and hopefully there still remains) an original, uncensored version of that press release. What information would it reveal about the mass production of 3000-mile rockets that U.S. Army inspectors reported were months away from striking the United States?

The following pages also give excerpts from some of the published inspectors' reports, which barely mentioned paper designs of advanced rockets and scrupulously avoided any mention of corresponding actual hardware. Those were likely also censored.

Where are the uncensored, full reports by these inspectors? Can they be located and declassified now?]

CIOS XXXII-125. *German Guided Missile Research.* 1945. pp. 5–7. [See pp. 5406–5417.]

A-Series of Missiles.

The complete A-series of weapons had 16 models designated A-0 through A-15. They are all associated with developments up to the V-2 or developments of improvements of the V-2 as it is known to have been used.

[Gives brief descriptions of A0 through A8 missiles]

A9 – Was the result of work on the A6, A7 and A8, and was a V-2 with wings so that instead of following a normal Hyperbolic trajectory, it would glide to earth after reaching a maximum height from the rocket propellant. Its range was increased to about 600-km or about 375 miles. Thus, the projectile could be launched well inside Germany, itself, and still reach England.

A10 – Was an experimental model of an additional thrust unit which was to be fastened to either the A4 (V-2) or the A-9 to give an additional range. It was to carry its own fuel, and when the fuel was completely burned the unit was released, at the same time starting the normal thrust unit in the A4 (V-2) or A9.

["Experimental model" sounds as if it had actually been constructed and tested.]

A-11, A12, A13 & A14 – Were development models of the A9-A10 series attempt—to produce a long range rocket projectile for attacks on the North American continent. The range strived for in these and the A15 model was 3500 miles.

A15 – Was to have been a 3500 mile range projectile using the A9 and A10 developments. This project probably never progressed beyond the drawing board stage.

[Since this comment is made about A15 but not the others, does that suggest that some or all of A10 through A14 had "progressed beyond the drawing board stage"?]

B. V-Series of Missiles.

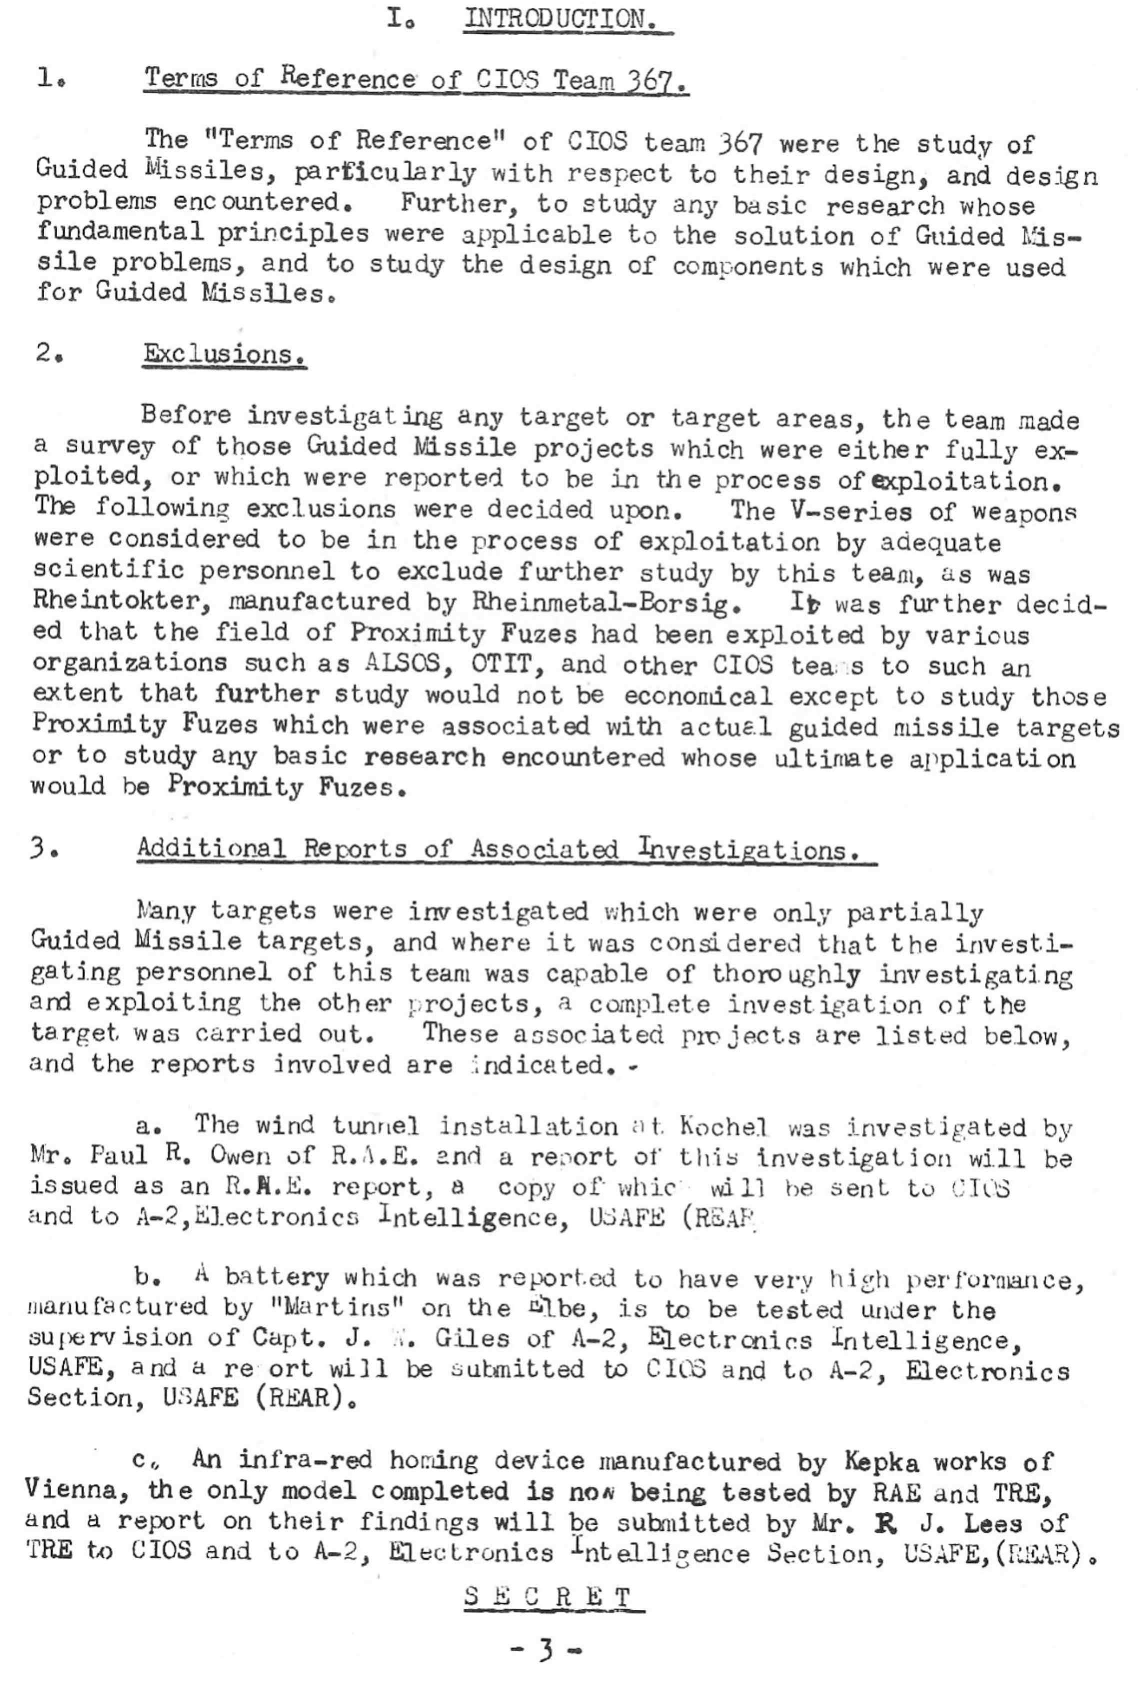
The V-series of missiles, four known types, two being used by the end of the war in Europe, have been covered by large numbers of technical investigation teams whose reports are available; therefore it was decided that CIOS Team 367 would not make a complete Technical Investigation of them. [...]

V1 – Was a jet propelled ground-to-ground missile which was aerodynamically stabilized. [...]

V2 – Was a rocket-propeled ground-to-ground missile which was not aerodynamically stabilized. [...] At the time CIOS team 367 was at Nordhausen, there were evacuation teams moving complete V2 units back to England (and the U.S.) for study, and firing trials; therefore, very little detailed study was made of the equipment. [...]

V3 – Was a larger version of the V1 with an incendiary warhead instead of the HE as normally used. Very little information is available concerning V3 control systems.

[Although a fourth V missile was mentioned above, it is not given even a brief description here. Was that information censored?]



I. INTRODUCTION.

1. Terms of Reference of CIOS Team 367.

The "Terms of Reference" of CIOS team 367 were the study of Guided Missiles, particularly with respect to their design, and design problems encountered. Further, to study any basic research whose fundamental principles were applicable to the solution of Guided Missile problems, and to study the design of components which were used for Guided Missiles.

2. Exclusions.

Before investigating any target or target areas, the team made a survey of those Guided Missile projects which were either fully exploited, or which were reported to be in the process of exploitation. The following exclusions were decided upon. The V-series of weapons were considered to be in the process of exploitation by adequate scientific personnel to exclude further study by this team, as was Rheintokter, manufactured by Rheinmetal-Borsig. It was further decided that the field of Proximity Fuzes had been exploited by various organizations such as ALSOS, OTIT, and other CIOS teams to such an extent that further study would not be economical except to study those Proximity Fuzes which were associated with actual guided missile targets or to study any basic research encountered whose ultimate application would be Proximity Fuzes.

3. Additional Reports of Associated Investigations.

Many targets were investigated which were only partially Guided Missile targets, and where it was considered that the investigating personnel of this team was capable of thoroughly investigating and exploiting the other projects, a complete investigation of the target was carried out. These associated projects are listed below, and the reports involved are indicated. -

a. The wind tunnel installation at Kochel was investigated by Mr. Paul R. Owen of R.A.E. and a report of this investigation will be issued as an R.A.E. report, a copy of which will be sent to CIOS and to A-2, Electronics Intelligence, USAFE (REAR

b. A battery which was reported to have very high performance, manufactured by "Martins" on the Elbe, is to be tested under the supervision of Capt. J. W. Giles of A-2, Electronics Intelligence, USAFE, and a report will be submitted to CIOS and to A-2, Electronics Section, USAFE (REAR).

c. An infra-red homing device manufactured by Kepka works of Vienna, the only model completed is now being tested by RAE and TRE, and a report on their findings will be submitted by Mr. R J. Lees of TRE to CIOS and to A-2, Electronics Intelligence Section, USAFE, (REAR).

II. GENERAL DISCUSSION OF GERMAN GUIDED-MISSILES PROJECTS.

1. Appendix 1 to this report is a chart which lists Guided Missiles. This chart is probably not complete but lists most of the types in the German war effort.

A - Series of Missiles.

The complete A-series of weapons had 16 models designated A-0 through A-15. They are all associated with developments up to the V-2 or developments of improvements of the V-2 as it is known to have been used.

The first six A-series models resulted in the V-2 weapon :-

Ao - Was the first attempt to develop a rocket motor whose thrust was sufficient to propel a 13.75 ton projectile. The Ao was never capable of sufficient thrust, however, through the study of the Ao, A1, A2, the small version of the V-2 was developed and became the A5.

A1, A2 & A3 - Were additional attempts to develop the thrust units and fuel for a V-2.

A4 - Development completed after the A5 had been successful. The V-2 was the production model of the A4.

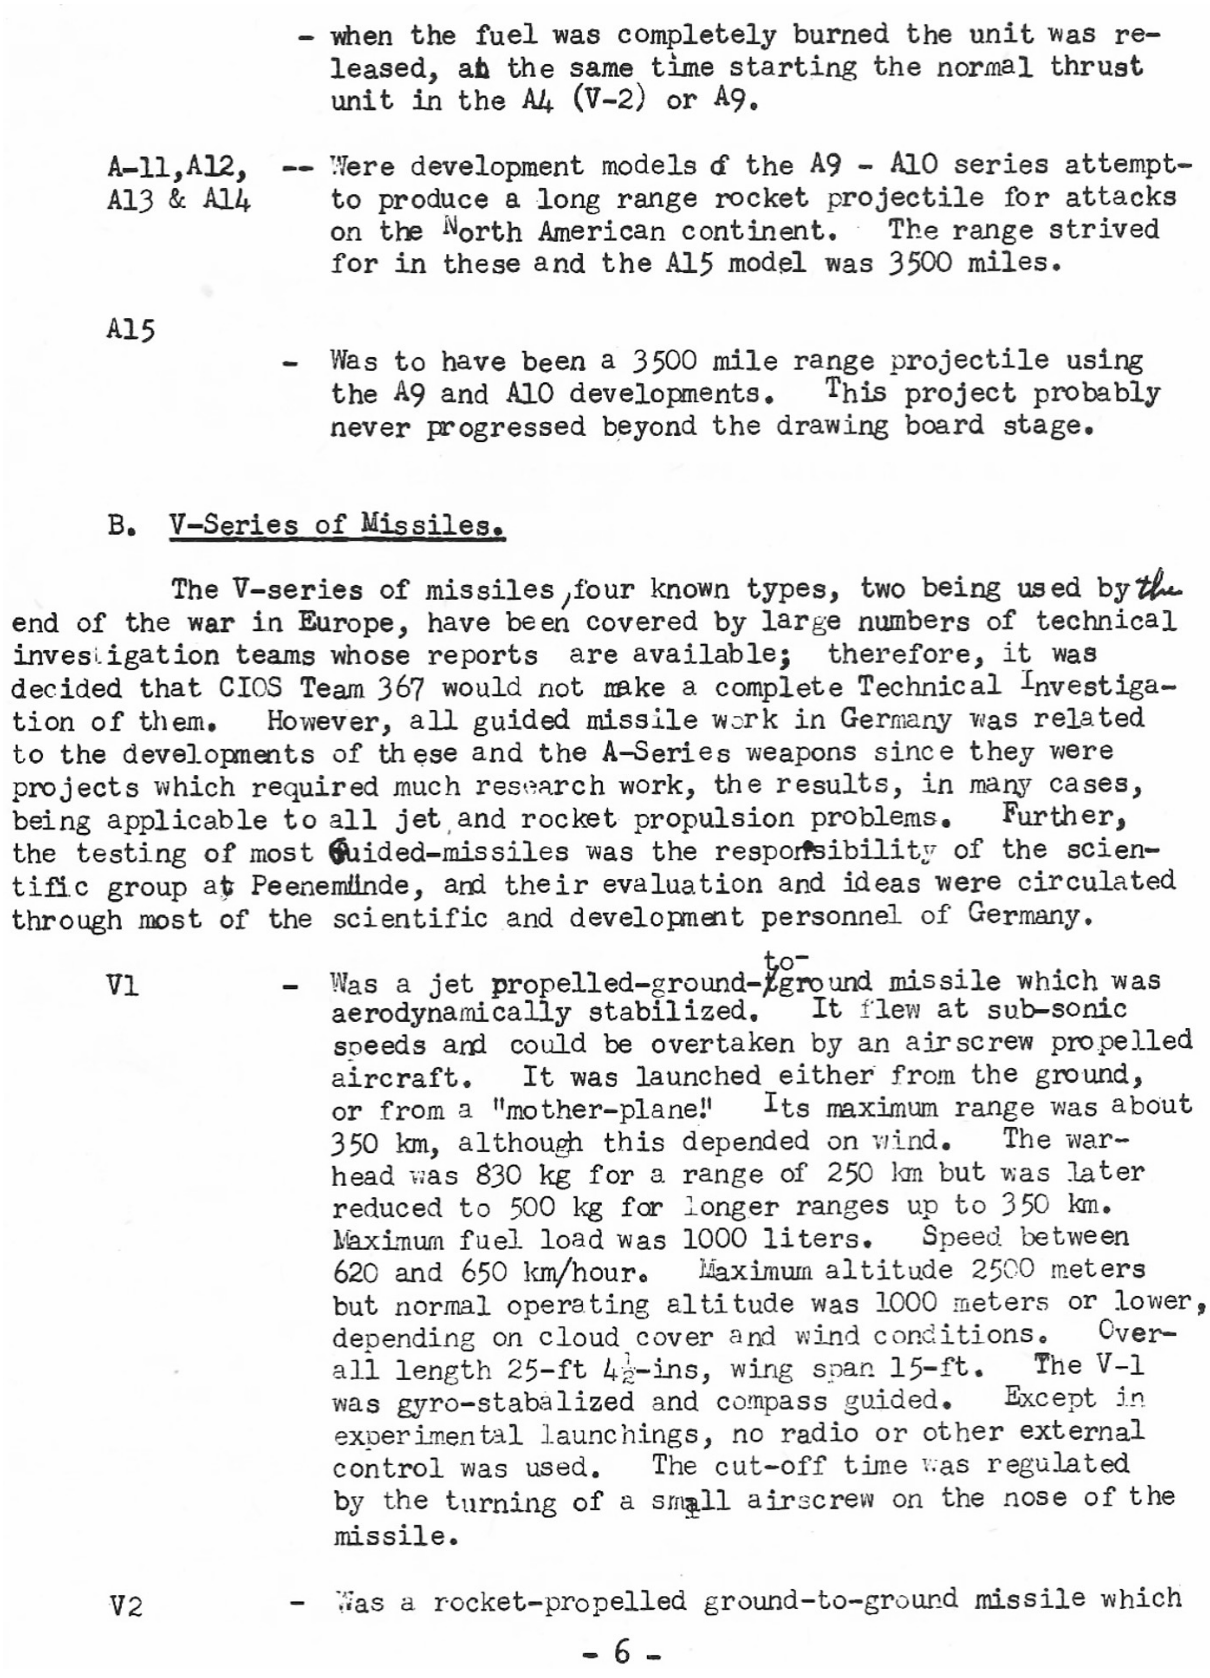
A5 - Was a small version of the V2. It was the first successful attempt at large scale, long range rocket propelled projectiles by Germany. Through the experience gained from the A5 and its predecessors Ao, A1, A2 and A3, the A4 (V-2) was finally perfected.

A6, A7 & A8. - Were experimental developments of the A4 (V-2) with the addition of wings so that the range could be incresed.

A9 - Was the result of work on the A6, A7 and A8, and was a V-2 with wings so that instead of following a normal Hyperbolic trajectory, it would glide to earth after reaching a maximum height from the rocket propellent. Its range was increased to about 600-km or about 375 miles. Thus, the projectile could be launched well inside Germany, itself, and still reach England.

A10 -Was an experimental model of an additional thrust unit which was to be fastened to either the A4 (V-2) or the A-9 to give an additional range. It was to carry its own fuel, and

Figure E.106: CIOS XXXII-125, *German Guided Missile Research.*



- when the fuel was completely burned the unit was released, at the same time starting the normal thrust unit in the A4 (V-2) or A9.

A-11, A12, A13 & A14 -- Were development models of the A9 - A10 series attempt to produce a long range rocket projectile for attacks on the North American continent. The range strived for in these and the A15 model was 3500 miles.

A15 - Was to have been a 3500 mile range projectile using the A9 and A10 developments. This project probably never progressed beyond the drawing board stage.

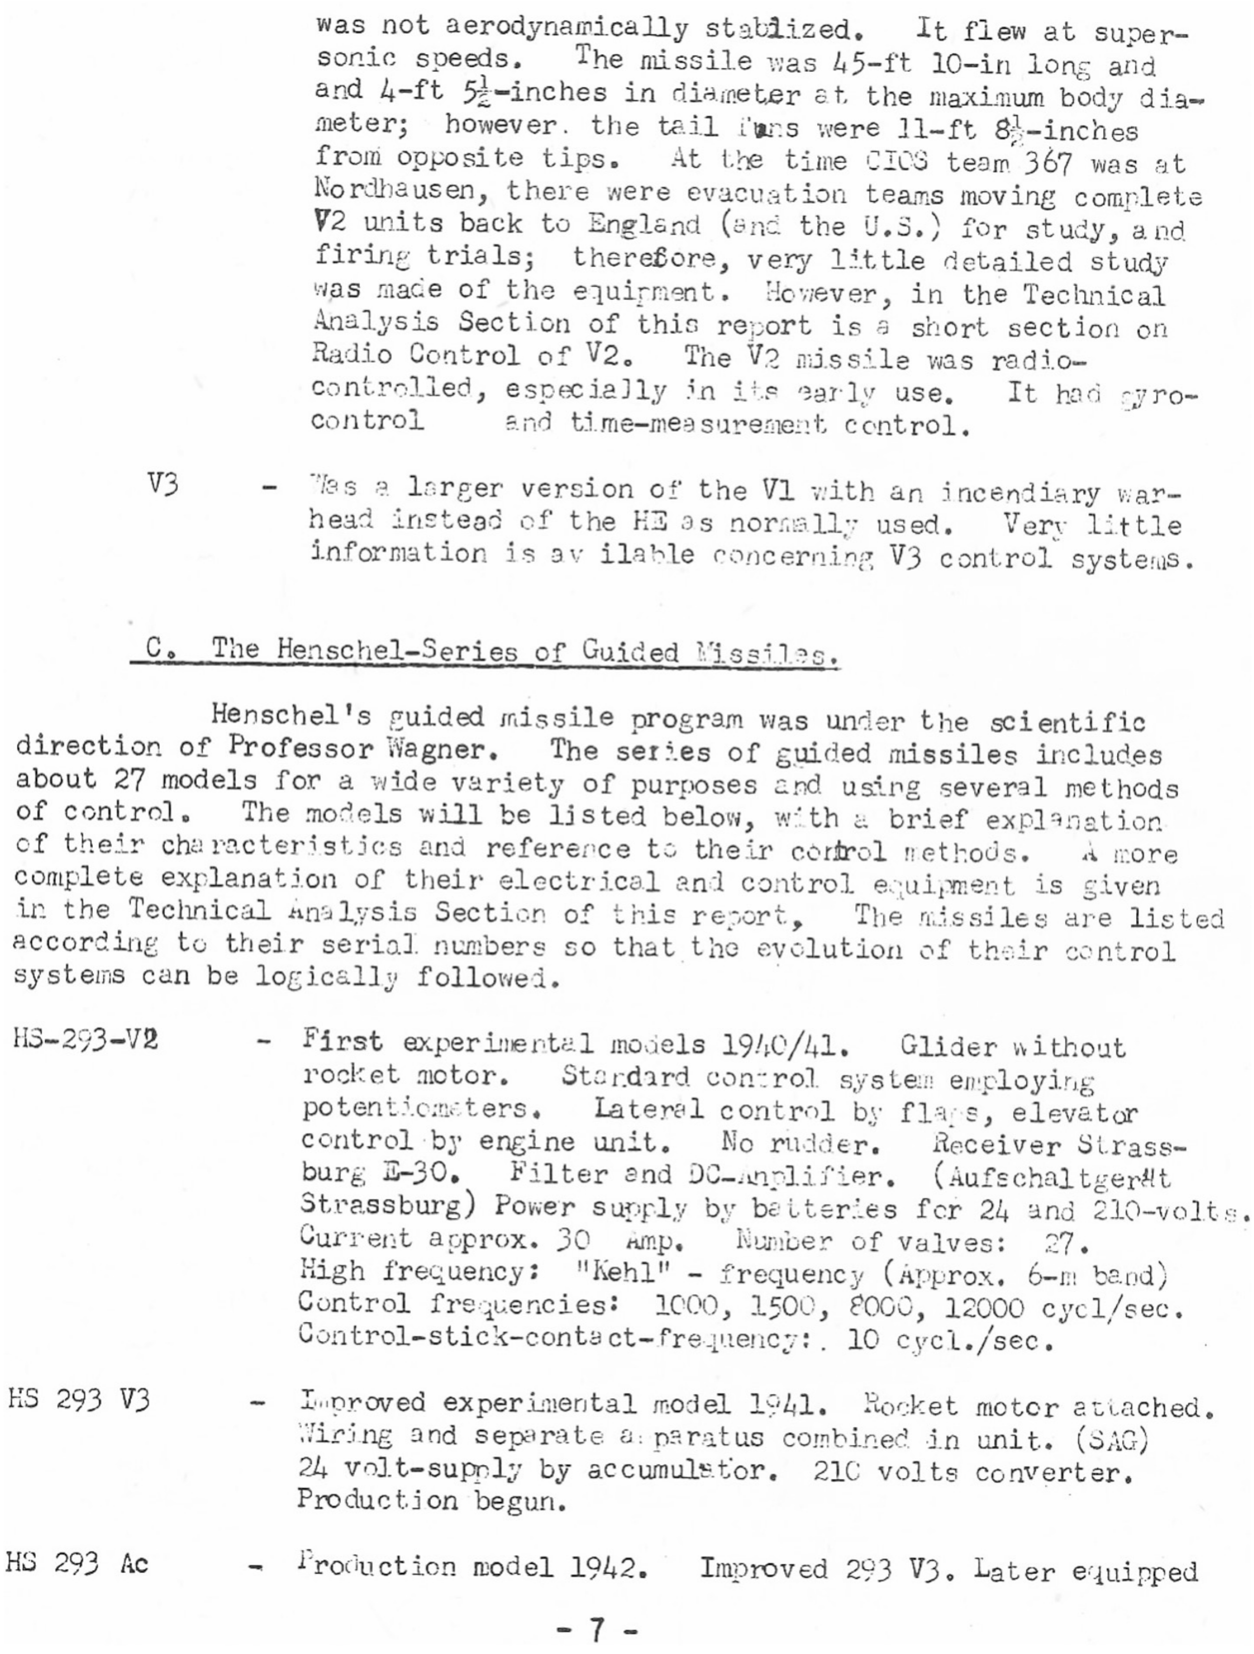
B. V-Series of Missiles.

The V-series of missiles, four known types, two being used by the end of the war in Europe, have been covered by large numbers of technical investigation teams whose reports are available; therefore, it was decided that CIOS Team 367 would not make a complete Technical Investigation of them. However, all guided missile work in Germany was related to the developments of these and the A-Series weapons since they were projects which required much research work, the results, in many cases, being applicable to all jet and rocket propulsion problems. Further, the testing of most Guided-missiles was the responsibility of the scientific group at Peenemünde, and their evaluation and ideas were circulated through most of the scientific and development personnel of Germany.

V1 - Was a jet propelled-ground-to-ground missile which was aerodynamically stabilized. It flew at sub-sonic speeds and could be overtaken by an airscrew propelled aircraft. It was launched either from the ground, or from a "mother-plane." Its maximum range was about 350 km, although this depended on wind. The warhead was 830 kg for a range of 250 km but was later reduced to 500 kg for longer ranges up to 350 km. Maximum fuel load was 1000 liters. Speed between 620 and 650 km/hour. Maximum altitude 2500 meters but normal operating altitude was 1000 meters or lower, depending on cloud cover and wind conditions. Overall length 25-ft $4\frac{1}{2}$-ins, wing span 15-ft. The V-1 was gyro-stabalized and compass guided. Except in experimental launchings, no radio or other external control was used. The cut-off time was regulated by the turning of a small airscrew on the nose of the missile.

V2 - Was a rocket-propelled ground-to-ground missile which

Figure E.107: CIOS XXXII-125, *German Guided Missile Research.*



was not aerodynamically stablized. It flew at supersonic speeds. The missile was 45-ft 10-in long and and 4-ft $5\frac{1}{2}$-inches in diameter at the maximum body diameter; however. the tail fins were 11-ft $8\frac{1}{2}$-inches from opposite tips. At the time CIOS team 367 was at Nordhausen, there were evacuation teams moving complete V2 units back to England (and the U.S.) for study, and firing trials; therefore, very little detailed study was made of the equipment. However, in the Technical Analysis Section of this report is a short section on Radio Control of V2. The V2 missile was radio-controlled, especially in its early use. It had gyro-control and time-measurement control.

V3 - Was a larger version of the V1 with an incendiary warhead instead of the HE as normally used. Very little information is available concerning V3 control systems.

C. The Henschel-Series of Guided Missiles.

Henschel's guided missile program was under the scientific direction of Professor Wagner. The series of guided missiles includes about 27 models for a wide variety of purposes and using several methods of control. The models will be listed below, with a brief explanation of their characteristics and reference to their control methods. A more complete explanation of their electrical and control equipment is given in the Technical Analysis Section of this report. The missiles are listed according to their serial numbers so that the evolution of their control systems can be logically followed.

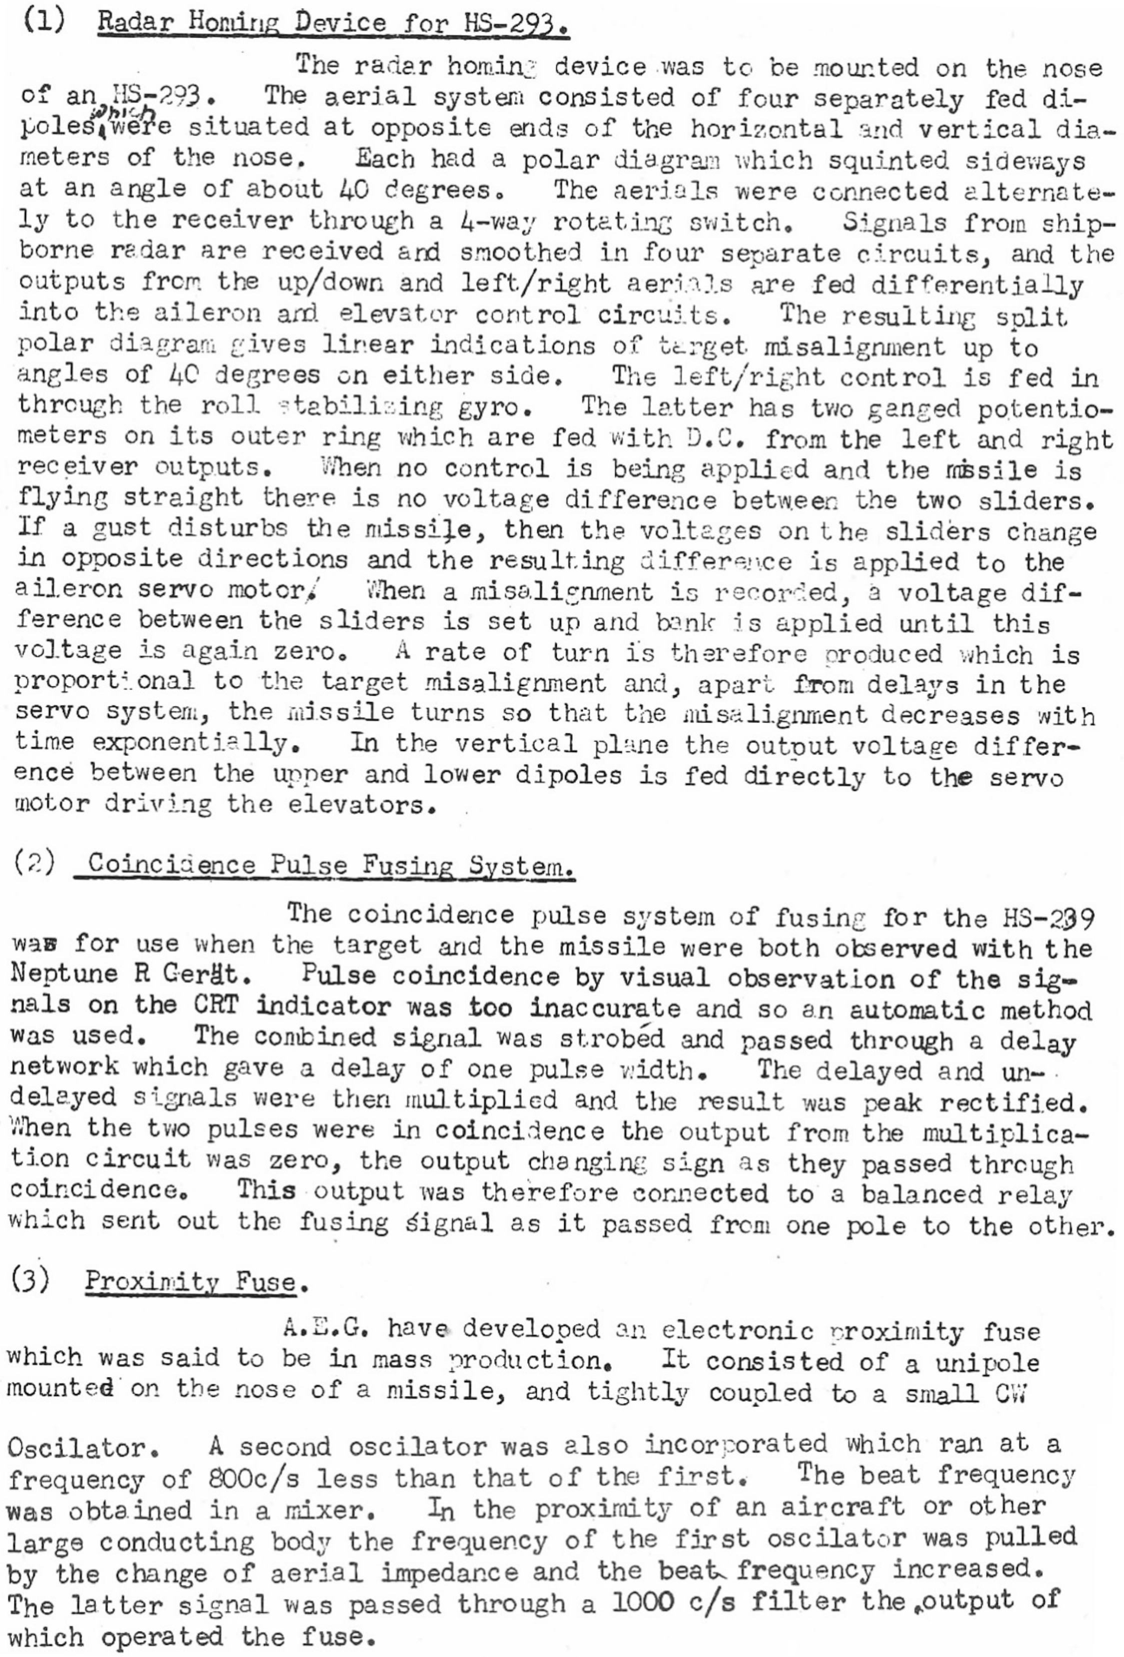
HS-293-V2 - First experimental models 1940/41. Glider without rocket motor. Standard control system employing potentiometers. Lateral control by flaps, elevator control by engine unit. No rudder. Receiver Strassburg E-30. Filter and DC-Amplifier. (Aufschaltgerät Strassburg) Power supply by batteries for 24 and 210-volts. Current approx. 30 Amp. Number of valves: 27. High frequency: "Kehl" - frequency (Approx. 6-m band) Control frequencies: 1000, 1500, 8000, 12000 cycl/sec. Control-stick-contact-frequency: 10 cycl./sec.

HS 293 V3 - Improved experimental model 1941. Rocket motor attached. Wiring and separate apparatus combined in unit. (SAG) 24 volt-supply by accumulator. 210 volts converter. Production begun.

HS 293 Ac - Production model 1942. Improved 293 V3. Later equipped

- 7 -

Figure E.108: CIOS XXXII-125, *German Guided Missile Research.*



(1) Radar Homing Device for HS-293.

The radar homing device was to be mounted on the nose of an HS-293. The aerial system consisted of four separately fed dipoles, which were situated at opposite ends of the horizontal and vertical diameters of the nose. Each had a polar diagram which squinted sideways at an angle of about 40 degrees. The aerials were connected alternately to the receiver through a 4-way rotating switch. Signals from shipborne radar are received and smoothed in four separate circuits, and the outputs from the up/down and left/right aerials are fed differentially into the aileron and elevator control circuits. The resulting split polar diagram gives linear indications of target misalignment up to angles of 40 degrees on either side. The left/right control is fed in through the roll stabilising gyro. The latter has two ganged potentiometers on its outer ring which are fed with D.C. from the left and right receiver outputs. When no control is being applied and the missile is flying straight there is no voltage difference between the two sliders. If a gust disturbs the missile, then the voltages on the sliders change in opposite directions and the resulting difference is applied to the aileron servo motor. When a misalignment is recorded, a voltage difference between the sliders is set up and bank is applied until this voltage is again zero. A rate of turn is therefore produced which is proportional to the target misalignment and, apart from delays in the servo system, the missile turns so that the misalignment decreases with time exponentially. In the vertical plane the output voltage difference between the upper and lower dipoles is fed directly to the servo motor driving the elevators.

(2) Coincidence Pulse Fusing System.

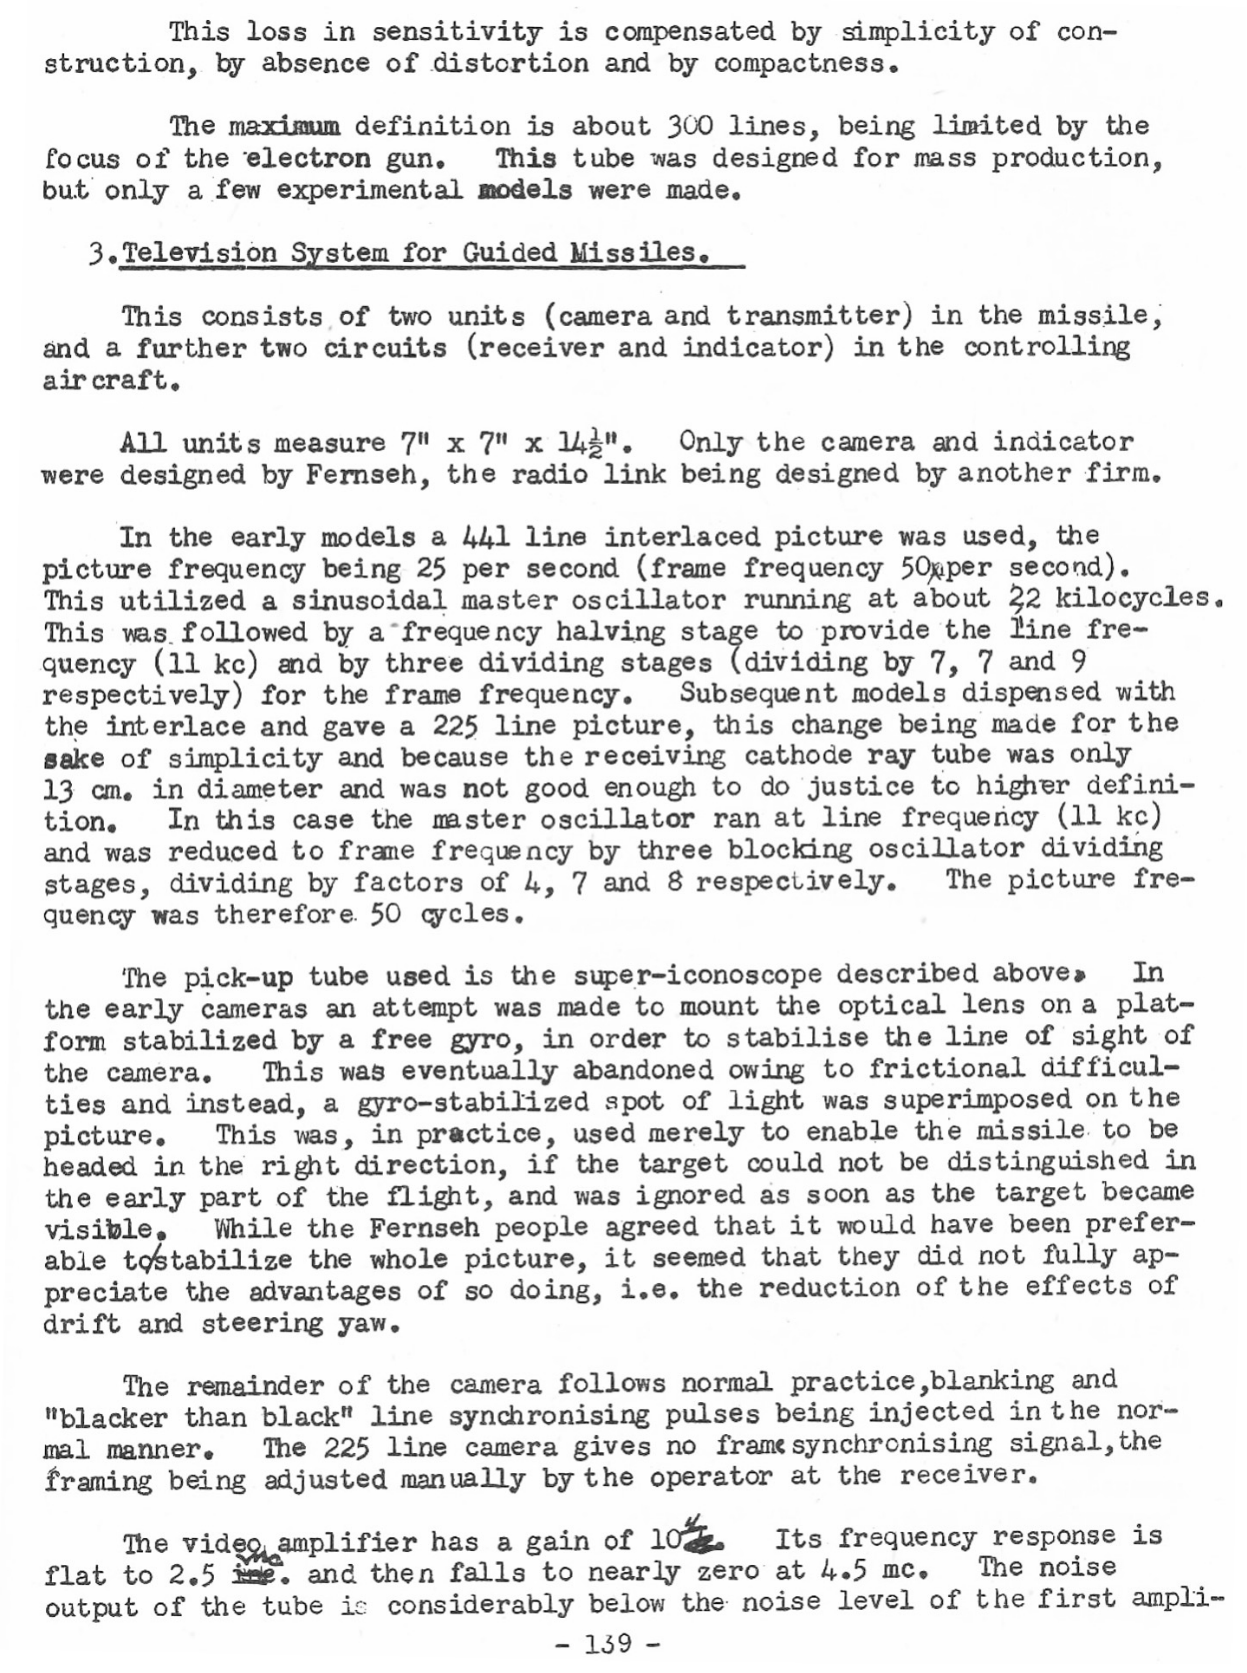
The coincidence pulse system of fusing for the HS-239 was for use when the target and the missile were both observed with the Neptune R Gerät. Pulse coincidence by visual observation of the signals on the CRT indicator was too inaccurate and so an automatic method was used. The combined signal was strobed and passed through a delay network which gave a delay of one pulse width. The delayed and undelayed signals were then multiplied and the result was peak rectified. When the two pulses were in coincidence the output from the multiplication circuit was zero, the output changing sign as they passed through coincidence. This output was therefore connected to a balanced relay which sent out the fusing signal as it passed from one pole to the other.

(3) Proximity Fuse.

A.E.G. have developed an electronic proximity fuse which was said to be in mass production. It consisted of a unipole mounted on the nose of a missile, and tightly coupled to a small CW

Oscilator. A second oscilator was also incorporated which ran at a frequency of 800c/s less than that of the first. The beat frequency was obtained in a mixer. In the proximity of an aircraft or other large conducting body the frequency of the first oscilator was pulled by the change of aerial impedance and the beat frequency increased. The latter signal was passed through a 1000 c/s filter the output of which operated the fuse.

Figure E.109: CIOS XXXII-125, *German Guided Missile Research.*



This loss in sensitivity is compensated by simplicity of construction, by absence of distortion and by compactness.

The maximum definition is about 300 lines, being limited by the focus of the electron gun. This tube was designed for mass production, but only a few experimental models were made.

3. Television System for Guided Missiles.

This consists of two units (camera and transmitter) in the missile, and a further two circuits (receiver and indicator) in the controlling aircraft.

All units measure 7" x 7" x 14½". Only the camera and indicator were designed by Fernseh, the radio link being designed by another firm.

In the early models a 441 line interlaced picture was used, the picture frequency being 25 per second (frame frequency 50 per second). This utilized a sinusoidal master oscillator running at about 22 kilocycles. This was followed by a frequency halving stage to provide the line frequency (11 kc) and by three dividing stages (dividing by 7, 7 and 9 respectively) for the frame frequency. Subsequent models dispensed with the interlace and gave a 225 line picture, this change being made for the sake of simplicity and because the receiving cathode ray tube was only 13 cm. in diameter and was not good enough to do justice to higher definition. In this case the master oscillator ran at line frequency (11 kc) and was reduced to frame frequency by three blocking oscillator dividing stages, dividing by factors of 4, 7 and 8 respectively. The picture frequency was therefore 50 cycles.

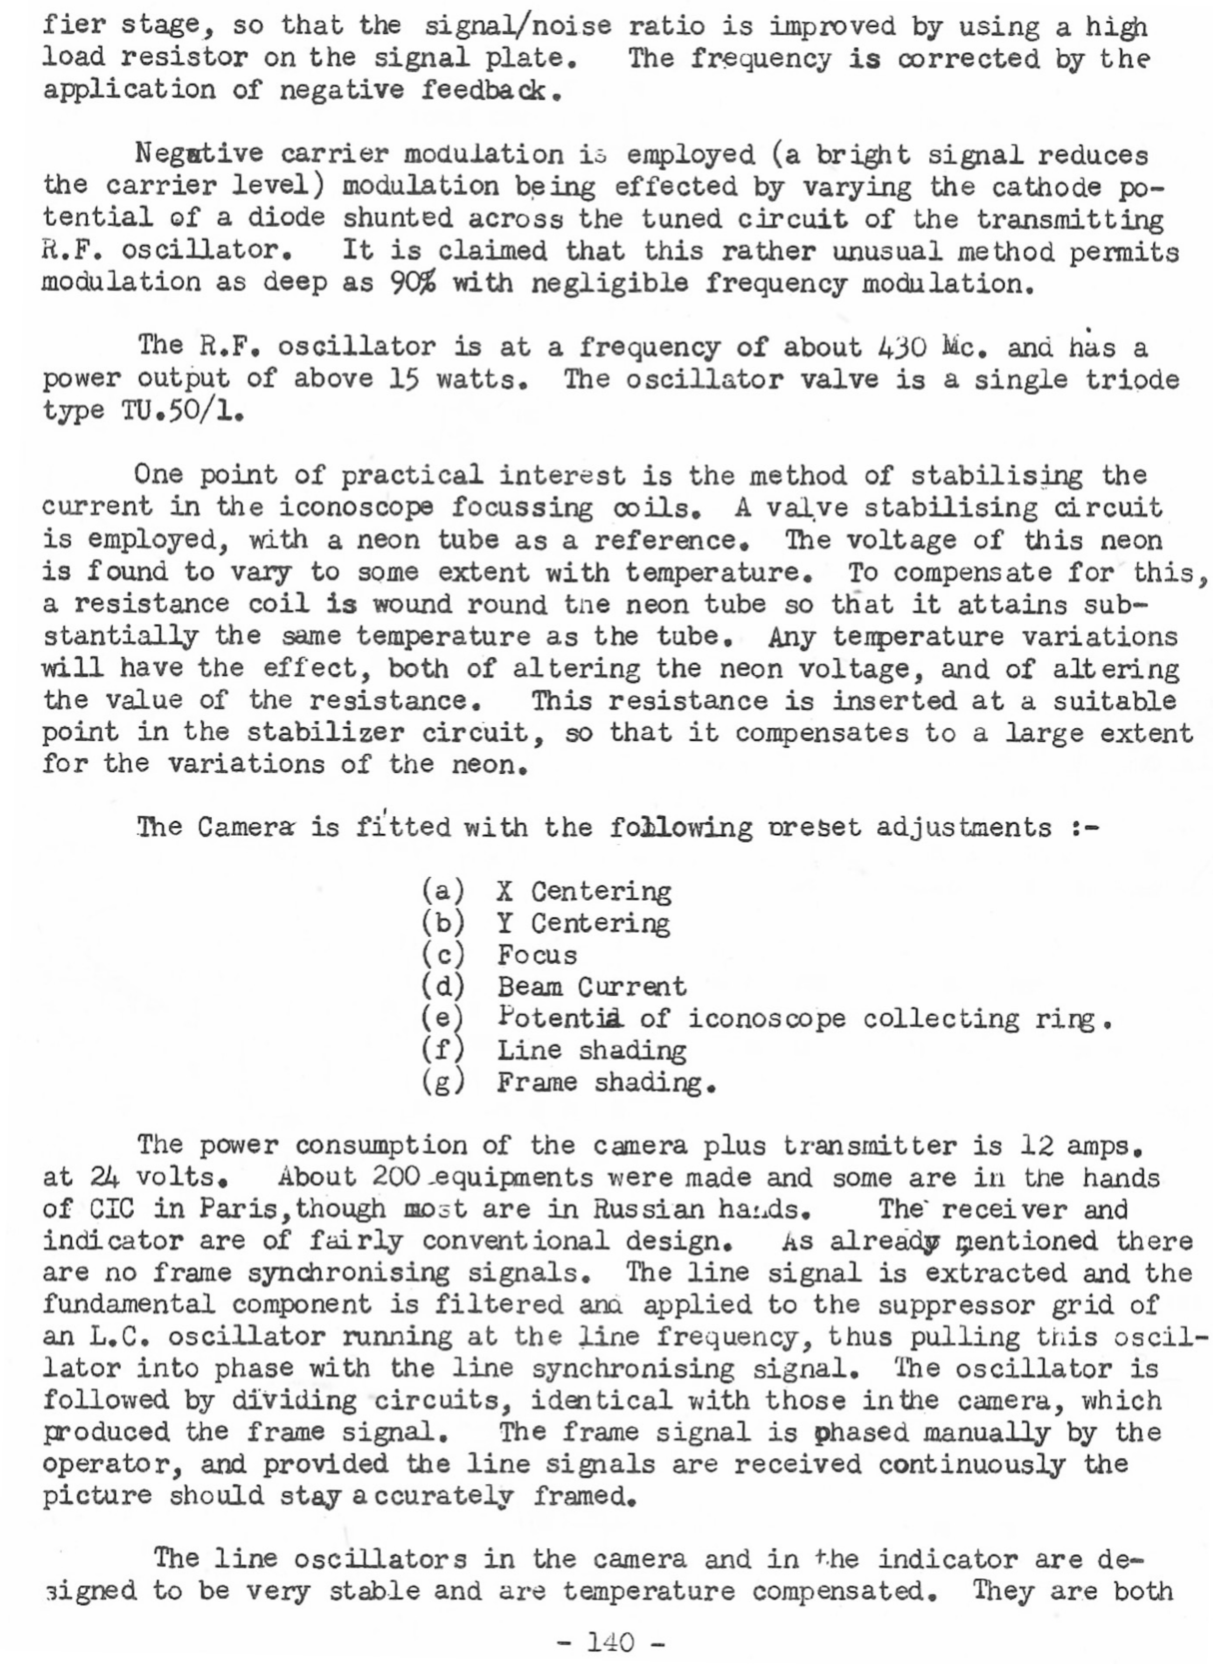
The pick-up tube used is the super-iconoscope described above. In the early cameras an attempt was made to mount the optical lens on a platform stabilized by a free gyro, in order to stabilise the line of sight of the camera. This was eventually abandoned owing to frictional difficulties and instead, a gyro-stabilized spot of light was superimposed on the picture. This was, in practice, used merely to enable the missile to be headed in the right direction, if the target could not be distinguished in the early part of the flight, and was ignored as soon as the target became visible. While the Fernseh people agreed that it would have been preferable to stabilize the whole picture, it seemed that they did not fully appreciate the advantages of so doing, i.e. the reduction of the effects of drift and steering yaw.

The remainder of the camera follows normal practice, blanking and "blacker than black" line synchronising pulses being injected in the normal manner. The 225 line camera gives no frame synchronising signal, the framing being adjusted manually by the operator at the receiver.

The video amplifier has a gain of 10^4. Its frequency response is flat to 2.5 ~~kc~~ mc. and then falls to nearly zero at 4.5 mc. The noise output of the tube is considerably below the noise level of the first ampli-

- 139 -

Figure E.110: CIOS XXXII-125, *German Guided Missile Research*.



fier stage, so that the signal/noise ratio is improved by using a high load resistor on the signal plate. The frequency is corrected by the application of negative feedback.

Negative carrier modulation is employed (a bright signal reduces the carrier level) modulation being effected by varying the cathode potential of a diode shunted across the tuned circuit of the transmitting R.F. oscillator. It is claimed that this rather unusual method permits modulation as deep as 90% with negligible frequency modulation.

The R.F. oscillator is at a frequency of about 430 Mc. and has a power output of above 15 watts. The oscillator valve is a single triode type TU.50/1.

One point of practical interest is the method of stabilising the current in the iconoscope focussing coils. A valve stabilising circuit is employed, with a neon tube as a reference. The voltage of this neon is found to vary to some extent with temperature. To compensate for this, a resistance coil is wound round the neon tube so that it attains substantially the same temperature as the tube. Any temperature variations will have the effect, both of altering the neon voltage, and of altering the value of the resistance. This resistance is inserted at a suitable point in the stabilizer circuit, so that it compensates to a large extent for the variations of the neon.

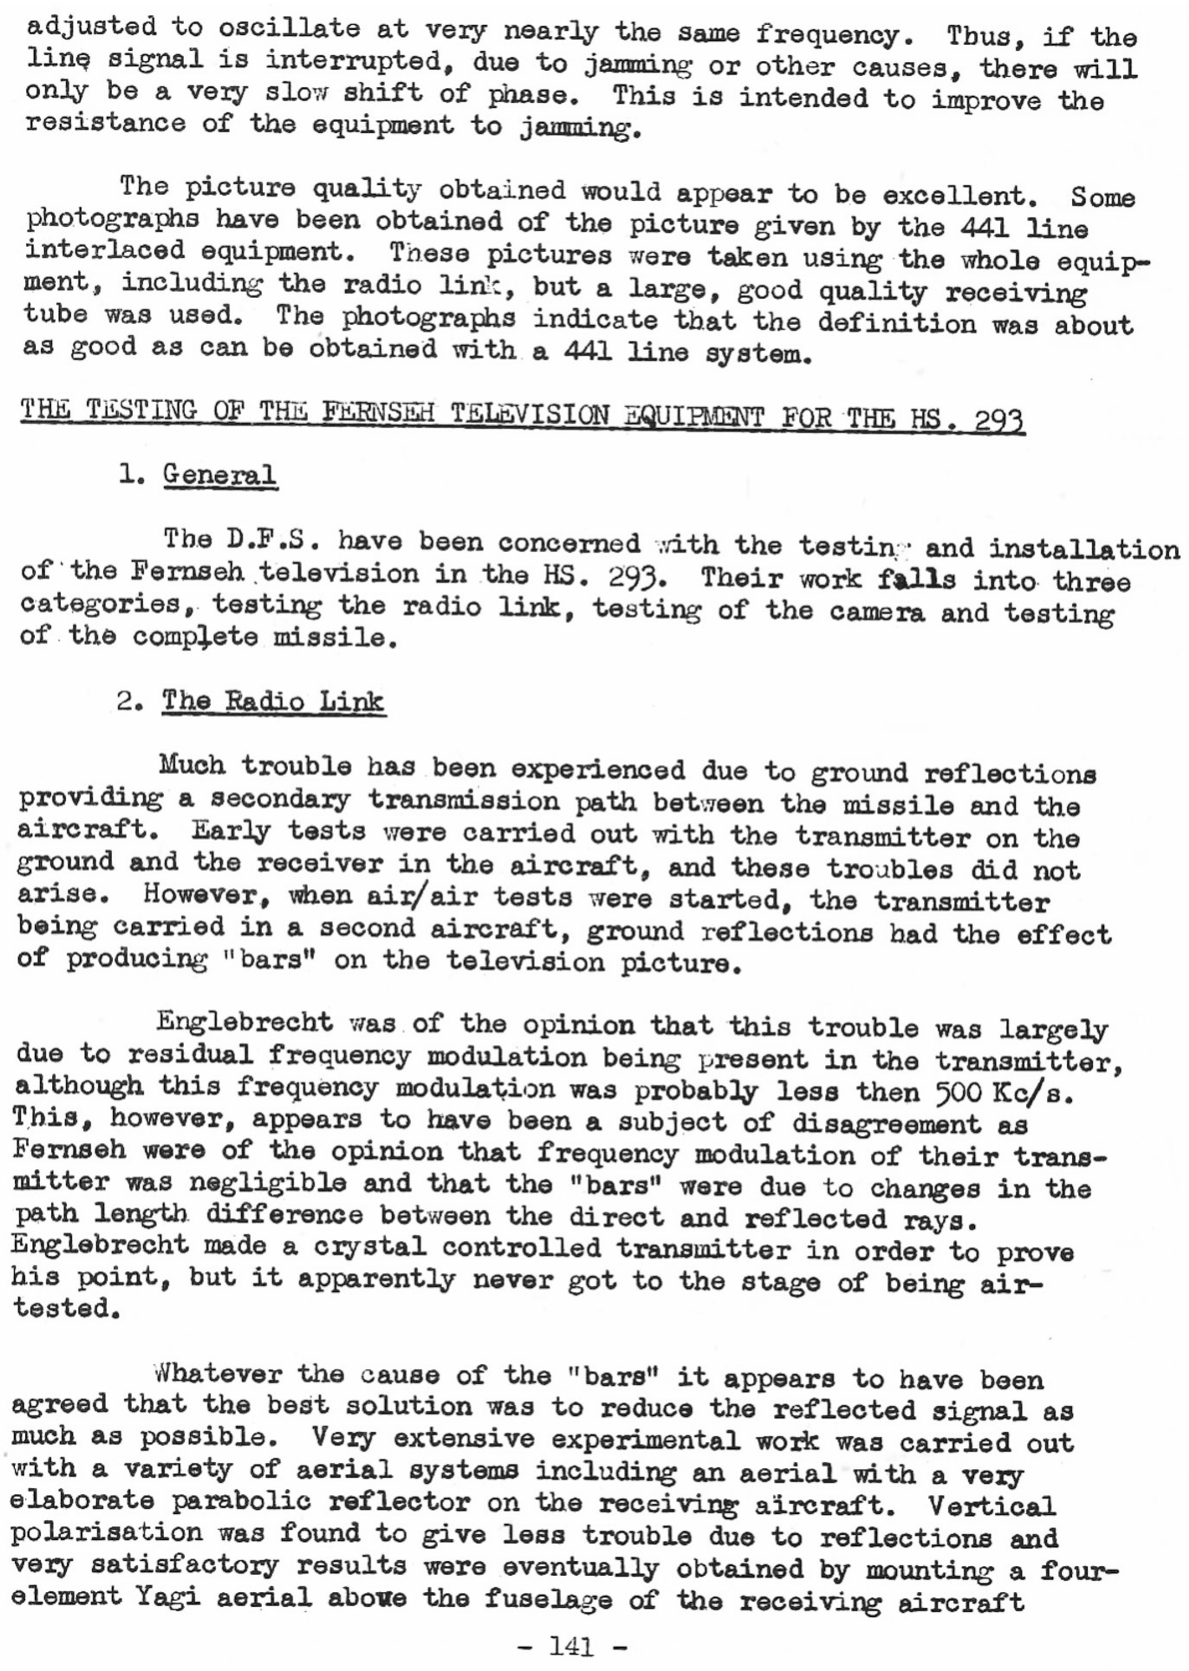
The Camera is fitted with the following preset adjustments :-

(a) X Centering
(b) Y Centering
(c) Focus
(d) Beam Current
(e) Potential of iconoscope collecting ring.
(f) Line shading
(g) Frame shading.

The power consumption of the camera plus transmitter is 12 amps. at 24 volts. About 200 equipments were made and some are in the hands of CIC in Paris, though most are in Russian hands. The receiver and indicator are of fairly conventional design. As already mentioned there are no frame synchronising signals. The line signal is extracted and the fundamental component is filtered and applied to the suppressor grid of an L.C. oscillator running at the line frequency, thus pulling this oscillator into phase with the line synchronising signal. The oscillator is followed by dividing circuits, identical with those in the camera, which produced the frame signal. The frame signal is phased manually by the operator, and provided the line signals are received continuously the picture should stay accurately framed.

The line oscillators in the camera and in the indicator are designed to be very stable and are temperature compensated. They are both

Figure E.111: CIOS XXXII-125, *German Guided Missile Research.*



adjusted to oscillate at very nearly the same frequency. Thus, if the line signal is interrupted, due to jamming or other causes, there will only be a very slow shift of phase. This is intended to improve the resistance of the equipment to jamming.

The picture quality obtained would appear to be excellent. Some photographs have been obtained of the picture given by the 441 line interlaced equipment. These pictures were taken using the whole equipment, including the radio link, but a large, good quality receiving tube was used. The photographs indicate that the definition was about as good as can be obtained with a 441 line system.

THE TESTING OF THE FERNSEH TELEVISION EQUIPMENT FOR THE HS. 293

1. General

The D.F.S. have been concerned with the testing and installation of the Fernseh television in the HS. 293. Their work falls into three categories, testing the radio link, testing of the camera and testing of the complete missile.

2. The Radio Link

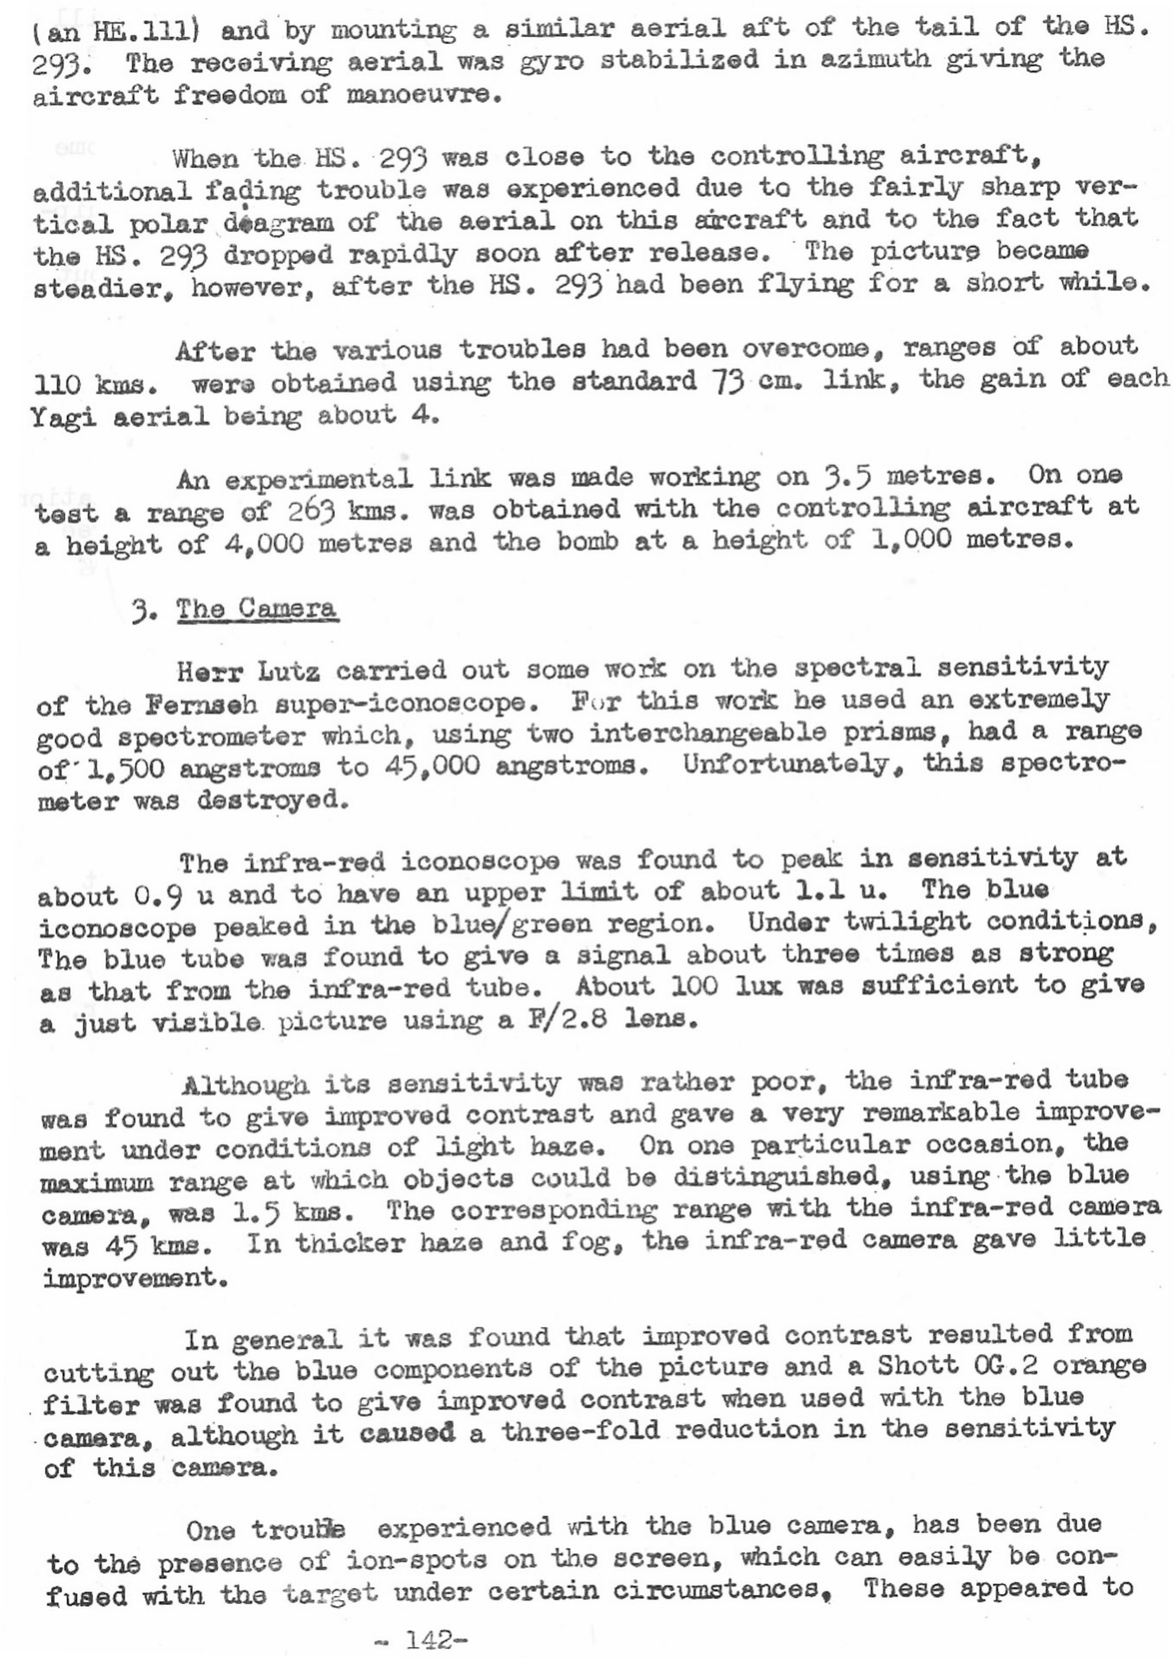
Much trouble has been experienced due to ground reflections providing a secondary transmission path between the missile and the aircraft. Early tests were carried out with the transmitter on the ground and the receiver in the aircraft, and these troubles did not arise. However, when air/air tests were started, the transmitter being carried in a second aircraft, ground reflections had the effect of producing "bars" on the television picture.

Englebrecht was of the opinion that this trouble was largely due to residual frequency modulation being present in the transmitter, although this frequency modulation was probably less then 500 Kc/s. This, however, appears to have been a subject of disagreement as Fernseh were of the opinion that frequency modulation of their transmitter was negligible and that the "bars" were due to changes in the path length difference between the direct and reflected rays. Englebrecht made a crystal controlled transmitter in order to prove his point, but it apparently never got to the stage of being air-tested.

Whatever the cause of the "bars" it appears to have been agreed that the best solution was to reduce the reflected signal as much as possible. Very extensive experimental work was carried out with a variety of aerial systems including an aerial with a very elaborate parabolic reflector on the receiving aircraft. Vertical polarisation was found to give less trouble due to reflections and very satisfactory results were eventually obtained by mounting a four-element Yagi aerial abowe the fuselage of the receiving aircraft

- 141 -

Figure E.112: CIOS XXXII-125, *German Guided Missile Research.*



(an HE.111) and by mounting a similar aerial aft of the tail of the HS. 293. The receiving aerial was gyro stabilized in azimuth giving the aircraft freedom of manoeuvre.

When the HS. 293 was close to the controlling aircraft, additional fading trouble was experienced due to the fairly sharp vertical polar diagram of the aerial on this aircraft and to the fact that the HS. 293 dropped rapidly soon after release. The picture became steadier, however, after the HS. 293 had been flying for a short while.

After the various troubles had been overcome, ranges of about 110 kms. were obtained using the standard 73 cm. link, the gain of each Yagi aerial being about 4.

An experimental link was made working on 3.5 metres. On one test a range of 263 kms. was obtained with the controlling aircraft at a height of 4,000 metres and the bomb at a height of 1,000 metres.

3. The Camera

Herr Lutz carried out some work on the spectral sensitivity of the Fernseh super-iconoscope. For this work he used an extremely good spectrometer which, using two interchangeable prisms, had a range of 1,500 angstroms to 45,000 angstroms. Unfortunately, this spectrometer was destroyed.

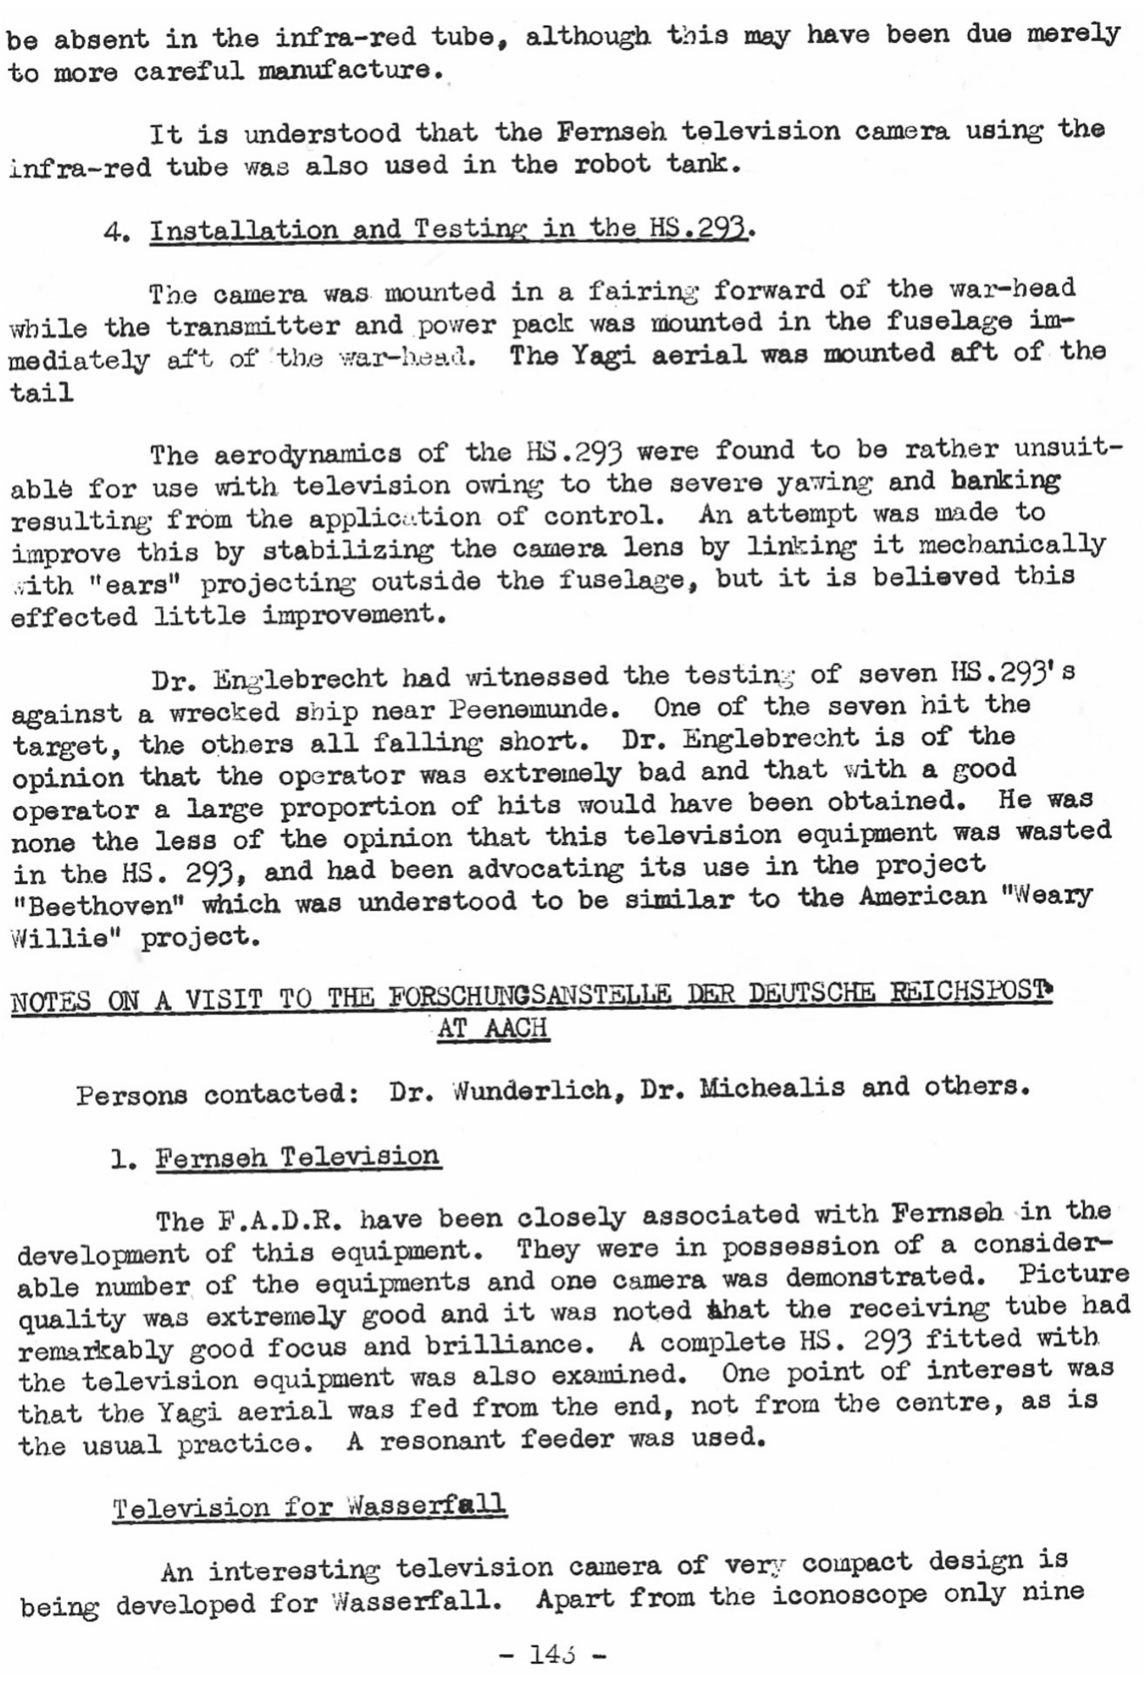
The infra-red iconoscope was found to peak in sensitivity at about 0.9 u and to have an upper limit of about 1.1 u. The blue iconoscope peaked in the blue/green region. Under twilight conditions, The blue tube was found to give a signal about three times as strong as that from the infra-red tube. About 100 lux was sufficient to give a just visible picture using a F/2.8 lens.

Although its sensitivity was rather poor, the infra-red tube was found to give improved contrast and gave a very remarkable improvement under conditions of light haze. On one particular occasion, the maximum range at which objects could be distinguished, using the blue camera, was 1.5 kms. The corresponding range with the infra-red camera was 45 kms. In thicker haze and fog, the infra-red camera gave little improvement.

In general it was found that improved contrast resulted from cutting out the blue components of the picture and a Shott OG.2 orange filter was found to give improved contrast when used with the blue camera, although it caused a three-fold reduction in the sensitivity of this camera.

One trouble experienced with the blue camera, has been due to the presence of ion-spots on the screen, which can easily be confused with the target under certain circumstances, These appeared to

Figure E.113: CIOS XXXII-125, *German Guided Missile Research.*



be absent in the infra-red tube, although this may have been due merely to more careful manufacture.

It is understood that the Fernseh television camera using the infra-red tube was also used in the robot tank.

4. Installation and Testing in the HS.293.

The camera was mounted in a fairing forward of the war-head while the transmitter and power pack was mounted in the fuselage immediately aft of the war-head. The Yagi aerial was mounted aft of the tail

The aerodynamics of the HS.293 were found to be rather unsuitable for use with television owing to the severe yawing and banking resulting from the application of control. An attempt was made to improve this by stabilizing the camera lens by linking it mechanically with "ears" projecting outside the fuselage, but it is believed this effected little improvement.

Dr. Englebrecht had witnessed the testing of seven HS.293's against a wrecked ship near Peenemunde. One of the seven hit the target, the others all falling short. Dr. Englebrecht is of the opinion that the operator was extremely bad and that with a good operator a large proportion of hits would have been obtained. He was none the less of the opinion that this television equipment was wasted in the HS. 293, and had been advocating its use in the project "Beethoven" which was understood to be similar to the American "Weary Willie" project.

NOTES ON A VISIT TO THE FORSCHUNGSANSTELLE DER DEUTSCHE REICHSPOST AT AACH

Persons contacted: Dr. Wunderlich, Dr. Michealis and others.

1. Fernseh Television

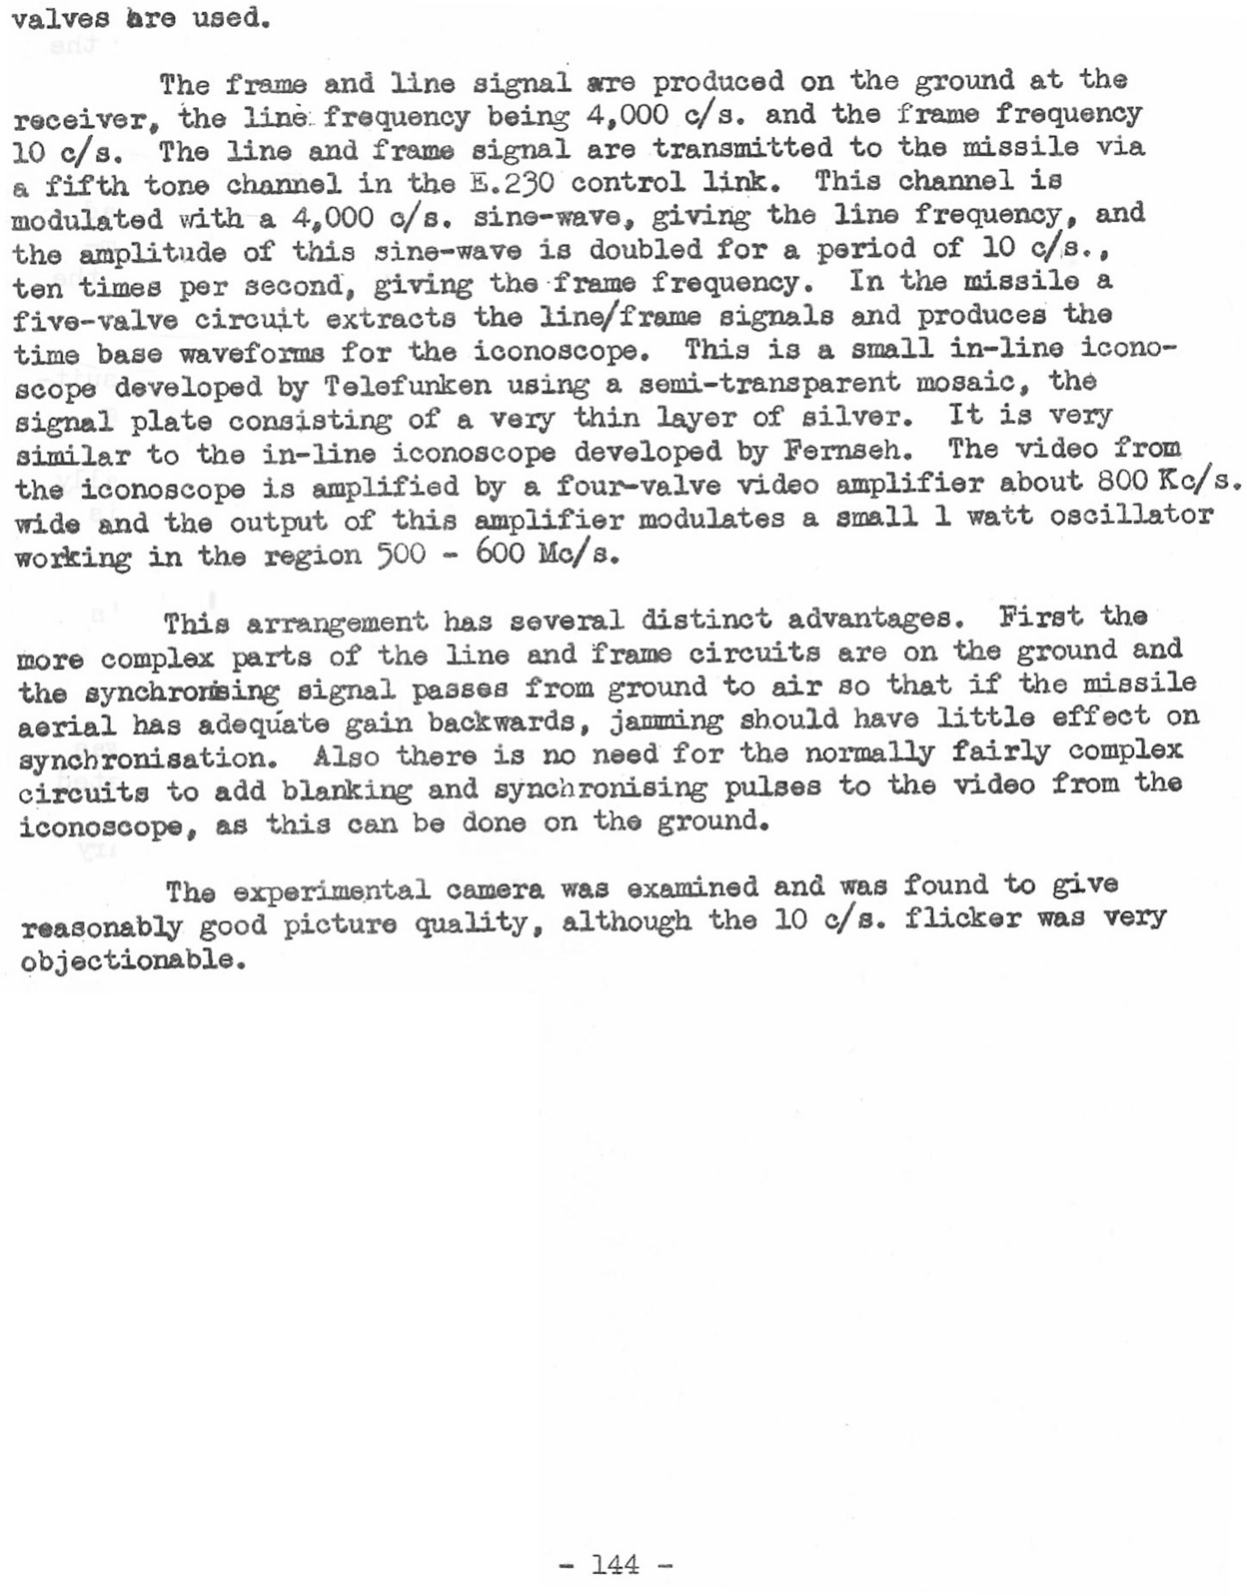
The F.A.D.R. have been closely associated with Fernseh in the development of this equipment. They were in possession of a considerable number of the equipments and one camera was demonstrated. Picture quality was extremely good and it was noted that the receiving tube had remarkably good focus and brilliance. A complete HS. 293 fitted with the television equipment was also examined. One point of interest was that the Yagi aerial was fed from the end, not from the centre, as is the usual practice. A resonant feeder was used.

Television for Wasserfall

An interesting television camera of very compact design is being developed for Wasserfall. Apart from the iconoscope only nine

- 143 -

Figure E.114: CIOS XXXII-125, *German Guided Missile Research.*



valves are used.

The frame and line signal are produced on the ground at the receiver, the line frequency being 4,000 c/s. and the frame frequency 10 c/s. The line and frame signal are transmitted to the missile via a fifth tone channel in the E.230 control link. This channel is modulated with a 4,000 c/s. sine-wave, giving the line frequency, and the amplitude of this sine-wave is doubled for a period of 10 c/s., ten times per second, giving the frame frequency. In the missile a five-valve circuit extracts the line/frame signals and produces the time base waveforms for the iconoscope. This is a small in-line iconoscope developed by Telefunken using a semi-transparent mosaic, the signal plate consisting of a very thin layer of silver. It is very similar to the in-line iconoscope developed by Fernseh. The video from the iconoscope is amplified by a four-valve video amplifier about 800 Kc/s. wide and the output of this amplifier modulates a small 1 watt oscillator working in the region 500 - 600 Mc/s.

This arrangement has several distinct advantages. First the more complex parts of the line and frame circuits are on the ground and the synchronising signal passes from ground to air so that if the missile aerial has adequate gain backwards, jamming should have little effect on synchronisation. Also there is no need for the normally fairly complex circuits to add blanking and synchronising pulses to the video from the iconoscope, as this can be done on the ground.

The experimental camera was examined and was found to give reasonably good picture quality, although the 10 c/s. flicker was very objectionable.

Figure E.115: CIOS XXXII-125, *German Guided Missile Research.*

[Note the quality, quantity, and variety of revolutionary new rockets and missiles listed in the table from CIOS XXXII-125 (p. 5407).

The table says that A15 was "never constructed" but does not make that statement about A10 through A14. Were some or all of those partially or fully constructed? The text of the report uses similar wording that suggests there may have been significant progress on rockets up to A14 (p. 5405).

For more information on both proximity fuses and anti-radar missiles (p. 5411), see Section 6.8.8.

For more information on miniaturized television cameras/transmitters and receivers/picture tubes (pp. 5412–5417), see Section 6.3.9).

For more information on robots with which the miniaturized television cameras could be used (p. 5416), see Section 6.7.4.]

CIOS XXVIII-45. *Investigation of Group 2 Targets in Nordhausen Area.* 1945.

[The mention on p. 12 of this report that Walther Riedel was located in Thuringia and brought to Nordhausen has made some authors wonder if Riedel may have still been at a Thuringian rocket installation other than Nordhausen.

The facts are much more unfortunate. Riedel was "found in a jail in Saalfeld, where U.S. soldiers had knocked out his teeth while questioning him about his alleged development of a 'bacteria bomb'" [Neufeld 2007, p. 206 and note 17 on p. 505 for Neufeld's sources]. Walther Riedel was a noted rocket engine designer, not a bacteriologist. The documented facts of this incident raise questions about both the intelligence and the morality of the U.S. forces operating at this place and time that do not appear to have been addressed in history books.

Of course, that information does nothing to settle questions about whether Riedel may have visited Thuringian rocket installations other than Nordhausen anytime prior to that time.]

Wolfgang Hirschfeld and Geoffrey Brooks. 1996. *Hirschfeld: The Story of a U-Boat NCO 1940-1946.* Annapolis, Maryland: Naval Institute Press. pp. 212–213.

Not long after, the stern lookouts reported the approach of a destroyer on the port quarter. This was the USS *Sutton*, which gave us orders by lamp to head for the Gulf of Maine and ignore all further communications from Halifax. [...]

Dr Schlicke had quietly joined me on the bridge and tossed a few rolls of microfilm into the sea. We watched them slowly sink. 'And there goes the rocket that could fly the Atlantic,' he told me.

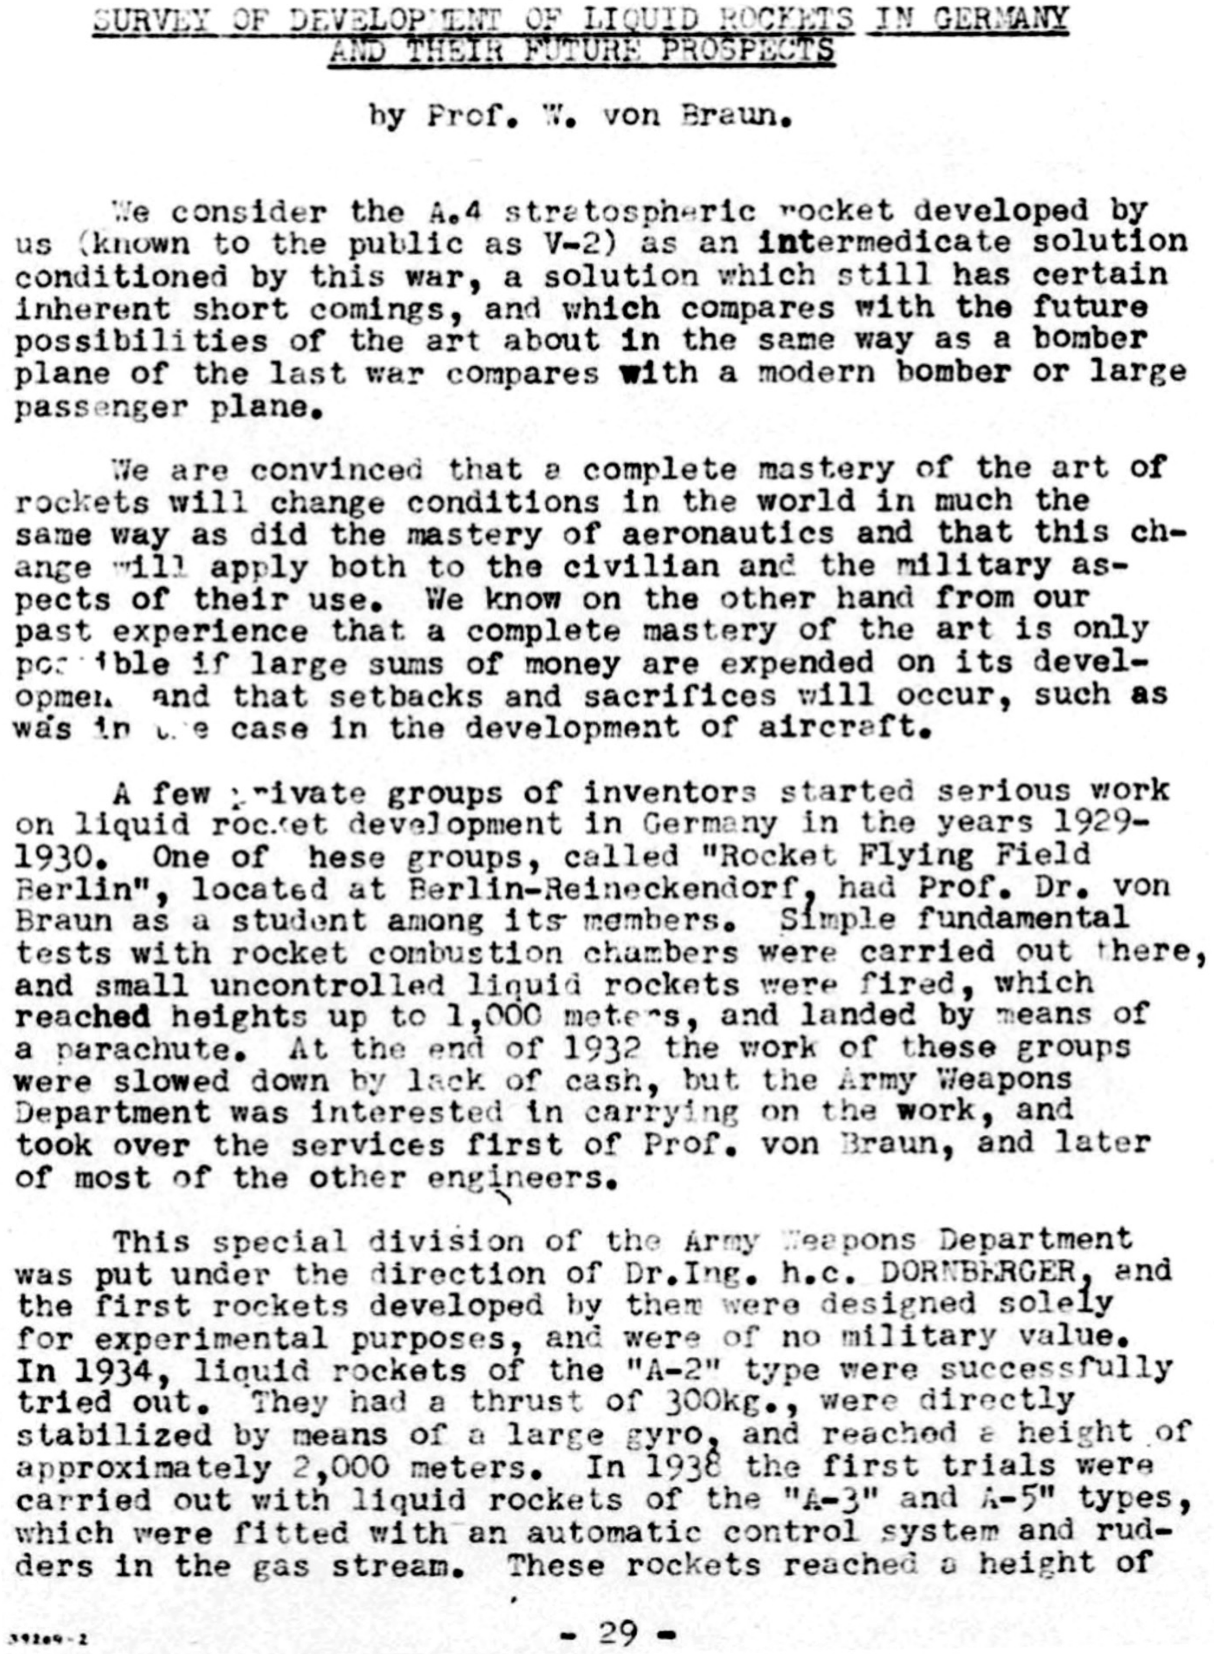
Unit History, 28th Air Disarmament Squadron (Prov), August 1945 [AFHRA A0708 frames 0758–0764]

C.I.C. Activity

One day this month a German civilian, a Herr Hering, presented himself at our installation gate and expressed a desire to speak with the Commanding Officer. He intimated that he had information of great value. The interview was granted and the German civilian was taken to Higher Headquarters after the C.O. was satisfied that the man was not "playing possum". As a result of this episode our country has been greatly enriched with pictures, blue prints and plans of Germany's dreaded jet and rocket bombs. To the German they are know as the Vergeltungs Waffe. To the American they are the V-1, V-2, V-3, and V-4. The majority of this squadron were subjected to incessant bombing by the V-1 and V-2 and are quite familiar with the horror and damage they create.

CIOS XXVIII-56. *Rockets and Guided Missiles.* 1945.

[One section of this report is an English translation of a short summary of rocket development written by Wernher von Braun. It provides useful information, although one must bear in mind that it would have been in von Braun's best personal interests to self-censor some details, and also that it would have been standard U.S. government procedure to further censor his account in making the English translation. See pp. 5420–5428.]



SURVEY OF DEVELOPMENT OF LIQUID ROCKETS IN GERMANY AND THEIR FUTURE PROSPECTS

by Prof. W. von Braun.

We consider the A.4 stratospheric rocket developed by us (known to the public as V-2) as an intermedicate solution conditioned by this war, a solution which still has certain inherent short comings, and which compares with the future possibilities of the art about in the same way as a bomber plane of the last war compares with a modern bomber or large passenger plane.

We are convinced that a complete mastery of the art of rockets will change conditions in the world in much the same way as did the mastery of aeronautics and that this change will apply both to the civilian and the military aspects of their use. We know on the other hand from our past experience that a complete mastery of the art is only possible if large sums of money are expended on its development and that setbacks and sacrifices will occur, such as was in the case in the development of aircraft.

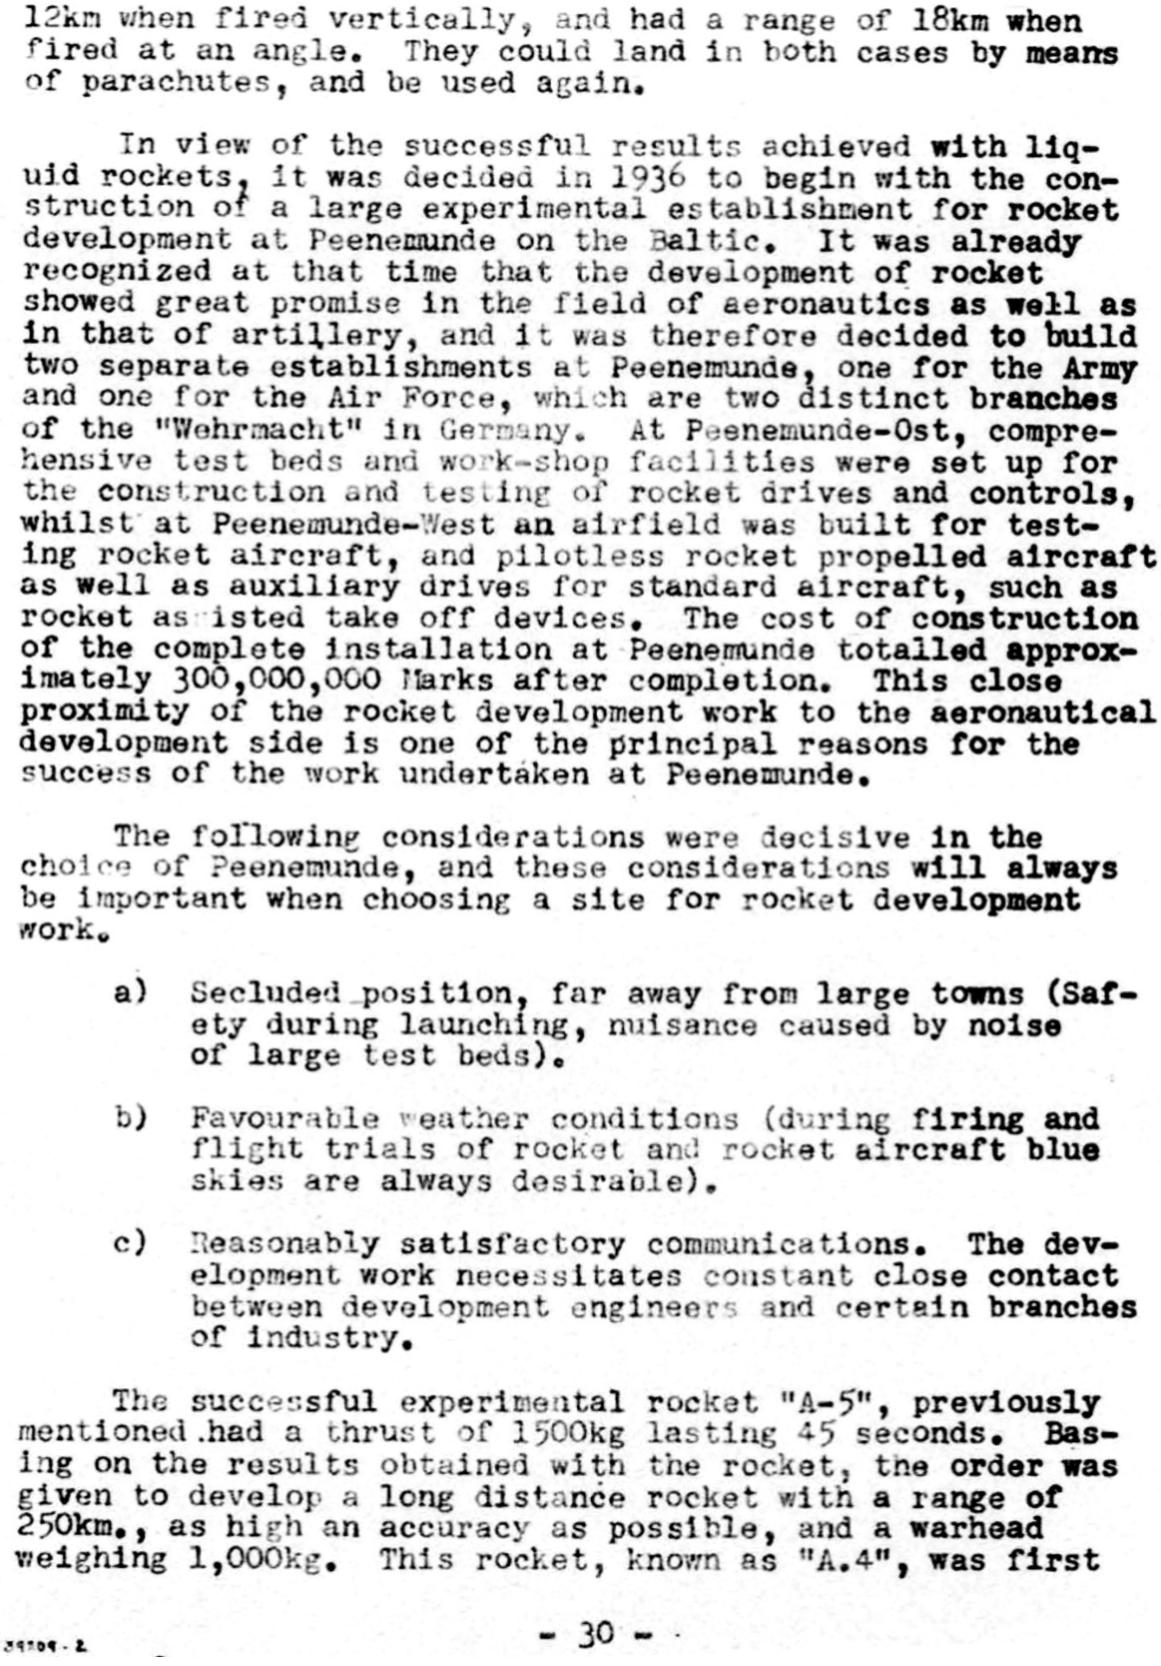
A few private groups of inventors started serious work on liquid rocket development in Germany in the years 1929-1930. One of these groups, called "Rocket Flying Field Berlin", located at Berlin-Reineckendorf, had Prof. Dr. von Braun as a student among its members. Simple fundamental tests with rocket combustion chambers were carried out there, and small uncontrolled liquid rockets were fired, which reached heights up to 1,000 meters, and landed by means of a parachute. At the end of 1932 the work of these groups were slowed down by lack of cash, but the Army Weapons Department was interested in carrying on the work, and took over the services first of Prof. von Braun, and later of most of the other engineers.

This special division of the Army Weapons Department was put under the direction of Dr.Ing. h.c. DORNBERGER, and the first rockets developed by them were designed solely for experimental purposes, and were of no military value. In 1934, liquid rockets of the "A-2" type were successfully tried out. They had a thrust of 300kg., were directly stabilized by means of a large gyro, and reached a height of approximately 2,000 meters. In 1938 the first trials were carried out with liquid rockets of the "A-3" and A-5" types, which were fitted with an automatic control system and rudders in the gas stream. These rockets reached a height of

39269-2

- 29 -

Figure E.116: CIOS XXVIII-56. *Rockets and Guided Missiles.*



12km when fired vertically, and had a range of 18km when fired at an angle. They could land in both cases by means of parachutes, and be used again.

In view of the successful results achieved with liquid rockets, it was decided in 1936 to begin with the construction of a large experimental establishment for rocket development at Peenemunde on the Baltic. It was already recognized at that time that the development of rocket showed great promise in the field of aeronautics as well as in that of artillery, and it was therefore decided to build two separate establishments at Peenemunde, one for the Army and one for the Air Force, which are two distinct branches of the "Wehrmacht" in Germany. At Peenemunde-Ost, comprehensive test beds and work-shop facilities were set up for the construction and testing of rocket drives and controls, whilst at Peenemunde-West an airfield was built for testing rocket aircraft, and pilotless rocket propelled aircraft, as well as auxiliary drives for standard aircraft, such as rocket assisted take off devices. The cost of construction of the complete installation at Peenemunde totalled approximately 300,000,000 Marks after completion. This close proximity of the rocket development work to the aeronautical development side is one of the principal reasons for the success of the work undertaken at Peenemunde.

The following considerations were decisive in the choice of Peenemunde, and these considerations will always be important when choosing a site for rocket development work.

a) Secluded position, far away from large towns (Safety during launching, nuisance caused by noise of large test beds).

b) Favourable weather conditions (during firing and flight trials of rocket and rocket aircraft blue skies are always desirable).

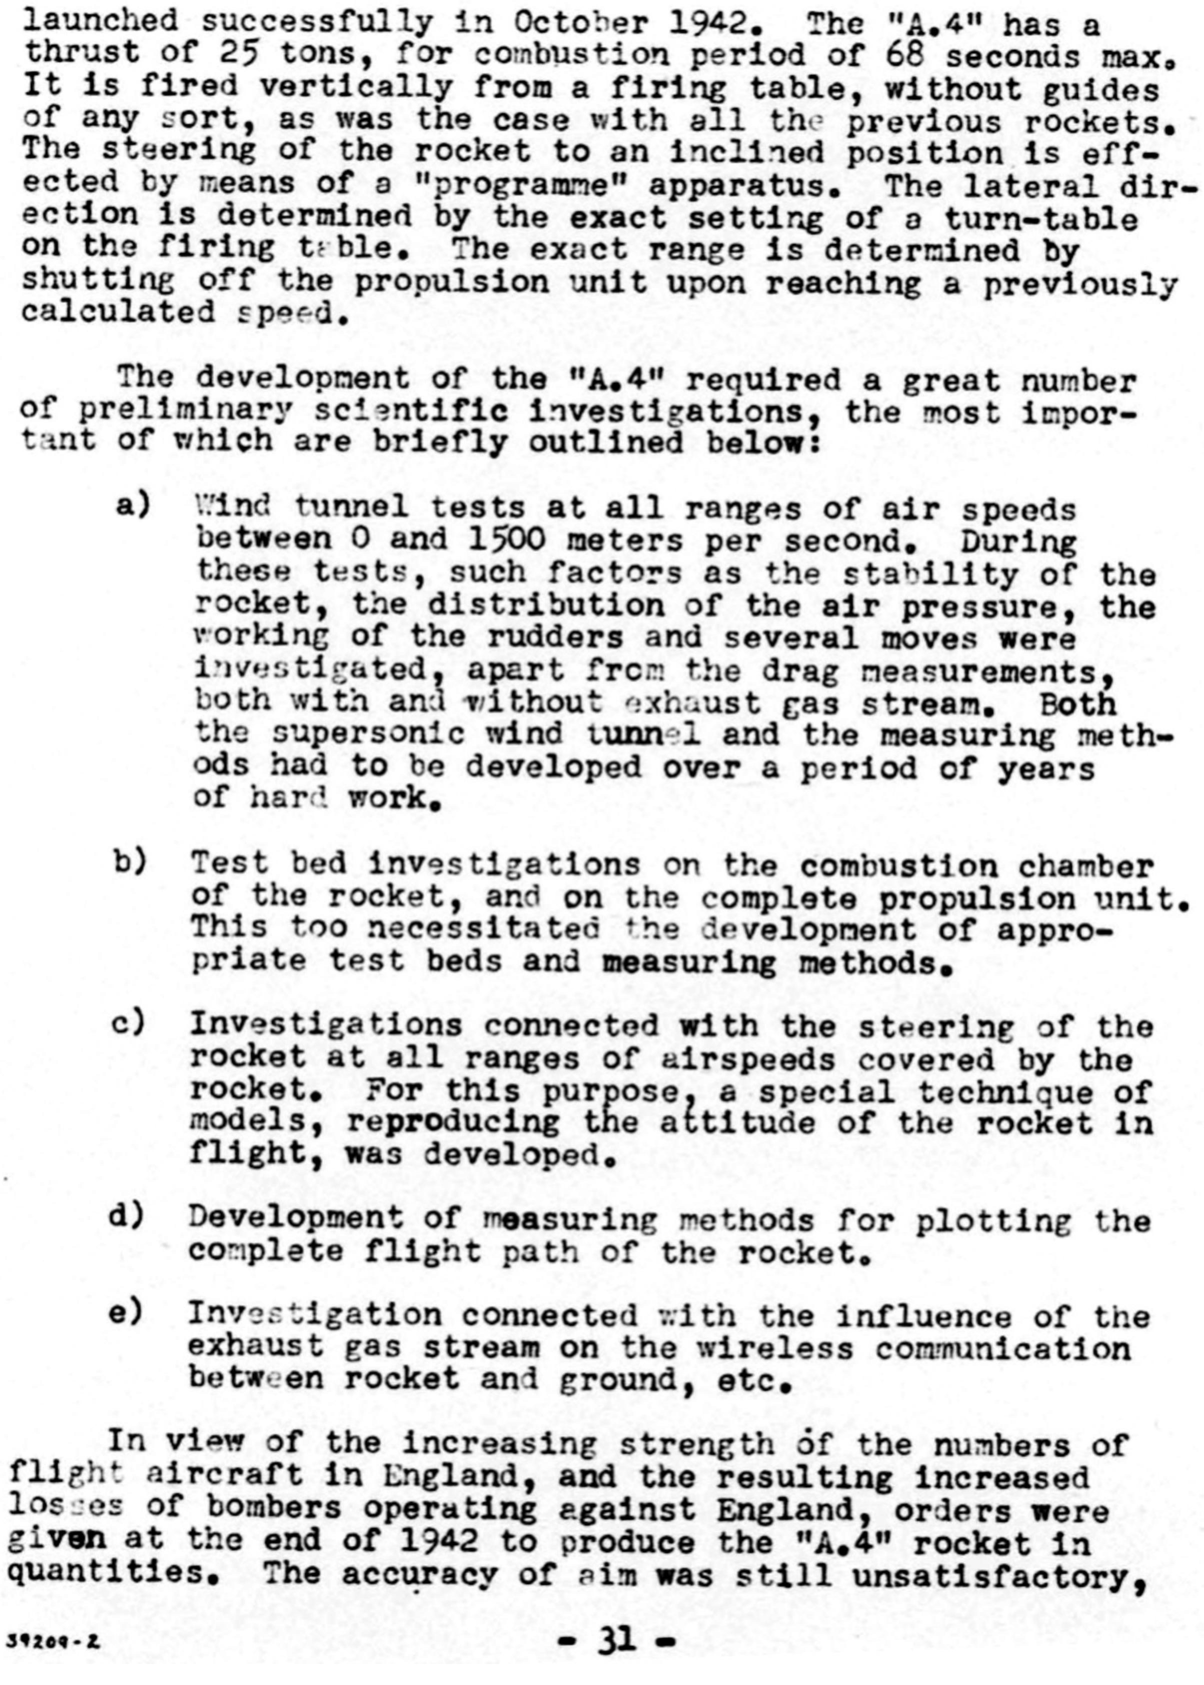
c) Reasonably satisfactory communications. The development work necessitates constant close contact between development engineers and certain branches of industry.

The successful experimental rocket "A-5", previously mentioned had a thrust of 1500kg lasting 45 seconds. Basing on the results obtained with the rocket, the order was given to develop a long distance rocket with a range of 250km., as high an accuracy as possible, and a warhead weighing 1,000kg. This rocket, known as "A.4", was first

- 30 -

39709-2

Figure E.117: CIOS XXVIII-56. *Rockets and Guided Missiles.*



launched successfully in October 1942. The "A.4" has a thrust of 25 tons, for combustion period of 68 seconds max. It is fired vertically from a firing table, without guides of any sort, as was the case with all the previous rockets. The steering of the rocket to an inclined position is effected by means of a "programme" apparatus. The lateral direction is determined by the exact setting of a turn-table on the firing table. The exact range is determined by shutting off the propulsion unit upon reaching a previously calculated speed.

The development of the "A.4" required a great number of preliminary scientific investigations, the most important of which are briefly outlined below:

a) Wind tunnel tests at all ranges of air speeds between 0 and 1500 meters per second. During these tests, such factors as the stability of the rocket, the distribution of the air pressure, the working of the rudders and several moves were investigated, apart from the drag measurements, both with and without exhaust gas stream. Both the supersonic wind tunnel and the measuring methods had to be developed over a period of years of hard work.

b) Test bed investigations on the combustion chamber of the rocket, and on the complete propulsion unit. This too necessitated the development of appropriate test beds and measuring methods.

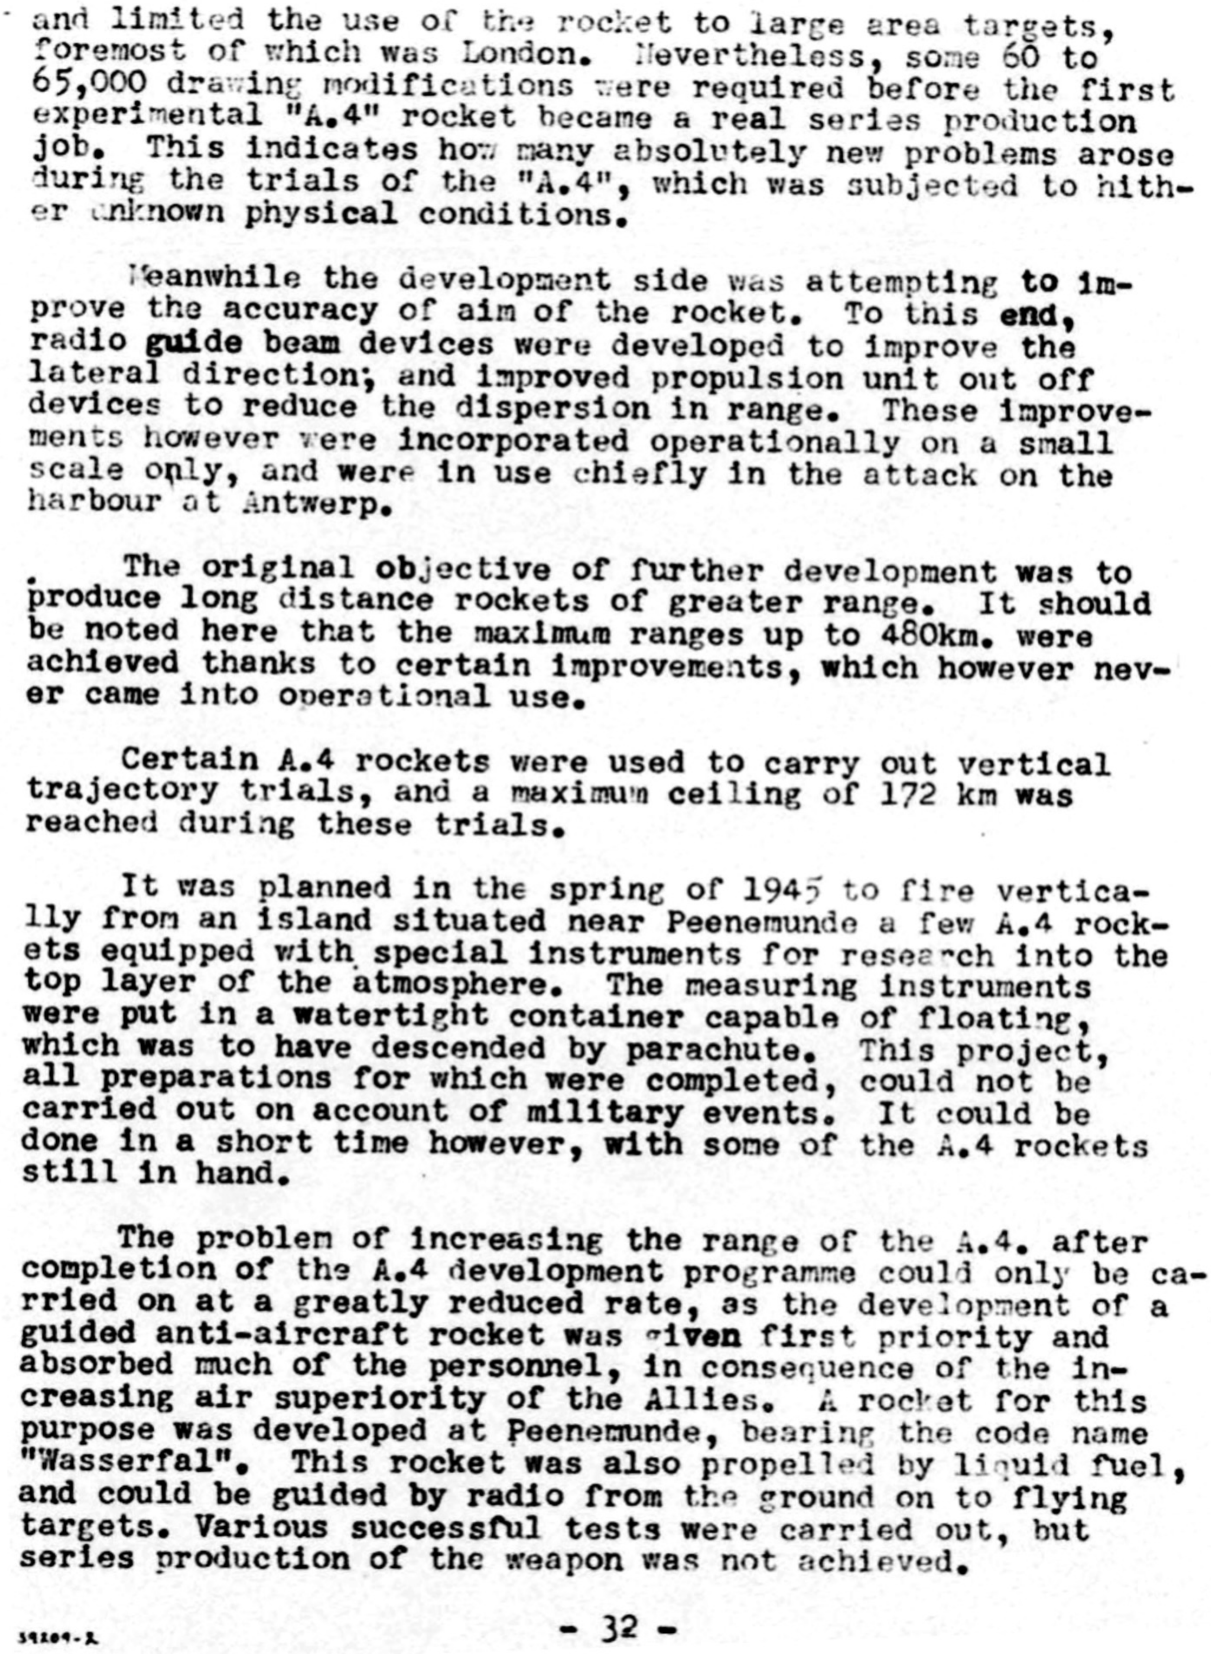
c) Investigations connected with the steering of the rocket at all ranges of airspeeds covered by the rocket. For this purpose, a special technique of models, reproducing the attitude of the rocket in flight, was developed.

d) Development of measuring methods for plotting the complete flight path of the rocket.

e) Investigation connected with the influence of the exhaust gas stream on the wireless communication between rocket and ground, etc.

In view of the increasing strength of the numbers of flight aircraft in England, and the resulting increased losses of bombers operating against England, orders were given at the end of 1942 to produce the "A.4" rocket in quantities. The accuracy of aim was still unsatisfactory,

Figure E.118: CIOS XXVIII-56. *Rockets and Guided Missiles.*



and limited the use of the rocket to large area targets, foremost of which was London. Nevertheless, some 60 to 65,000 drawing modifications were required before the first experimental "A.4" rocket became a real series production job. This indicates how many absolutely new problems arose during the trials of the "A.4", which was subjected to hither unknown physical conditions.

Meanwhile the development side was attempting to improve the accuracy of aim of the rocket. To this end, radio guide beam devices were developed to improve the lateral direction; and improved propulsion unit out off devices to reduce the dispersion in range. These improvements however were incorporated operationally on a small scale only, and were in use chiefly in the attack on the harbour at Antwerp.

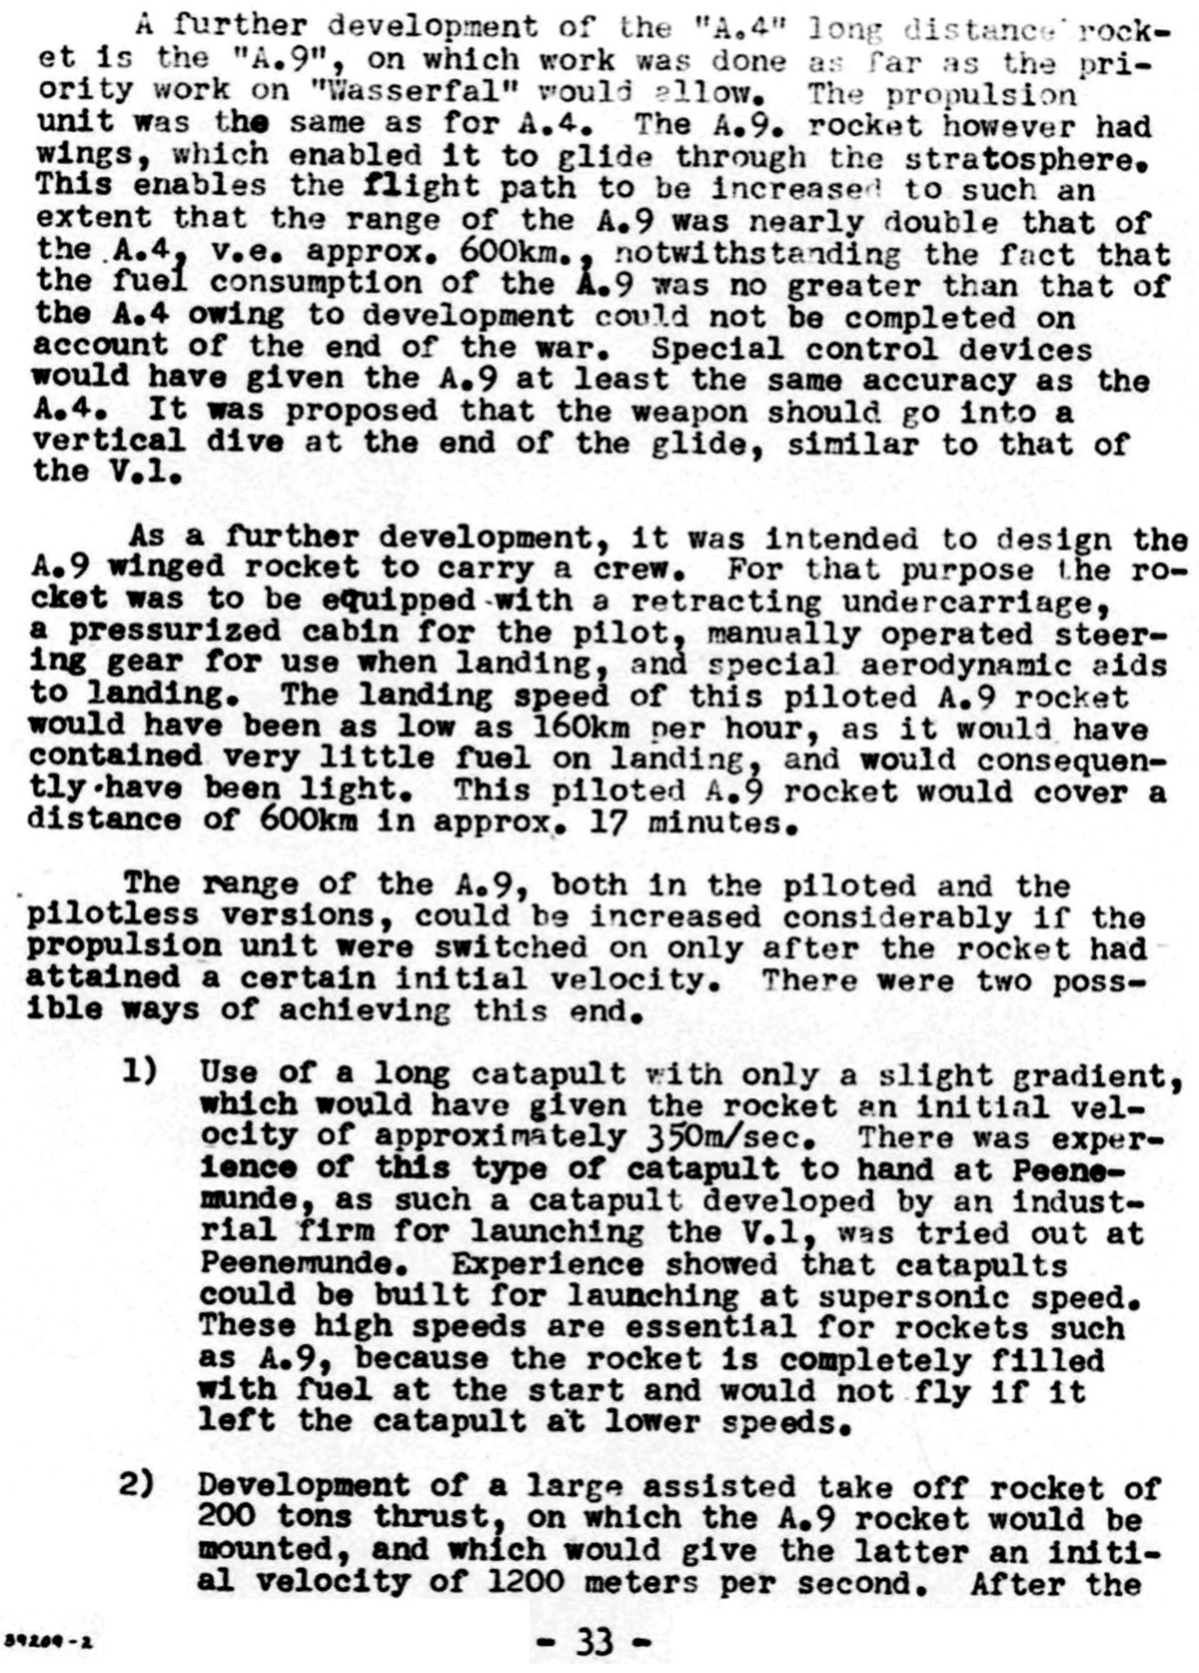
The original objective of further development was to produce long distance rockets of greater range. It should be noted here that the maximum ranges up to 480km. were achieved thanks to certain improvements, which however never came into operational use.

Certain A.4 rockets were used to carry out vertical trajectory trials, and a maximum ceiling of 172 km was reached during these trials.

It was planned in the spring of 1945 to fire vertically from an island situated near Peenemunde a few A.4 rockets equipped with special instruments for research into the top layer of the atmosphere. The measuring instruments were put in a watertight container capable of floating, which was to have descended by parachute. This project, all preparations for which were completed, could not be carried out on account of military events. It could be done in a short time however, with some of the A.4 rockets still in hand.

The problem of increasing the range of the A.4. after completion of the A.4 development programme could only be carried on at a greatly reduced rate, as the development of a guided anti-aircraft rocket was given first priority and absorbed much of the personnel, in consequence of the increasing air superiority of the Allies. A rocket for this purpose was developed at Peenemunde, bearing the code name "Wasserfal". This rocket was also propelled by liquid fuel, and could be guided by radio from the ground on to flying targets. Various successful tests were carried out, but series production of the weapon was not achieved.

Figure E.119: CIOS XXVIII-56. *Rockets and Guided Missiles.*



A further development of the "A.4" long distance rocket is the "A.9", on which work was done as far as the priority work on "Wasserfal" would allow. The propulsion unit was the same as for A.4. The A.9. rocket however had wings, which enabled it to glide through the stratosphere. This enables the flight path to be increased to such an extent that the range of the A.9 was nearly double that of the A.4, v.e. approx. 600km., notwithstanding the fact that the fuel consumption of the A.9 was no greater than that of the A.4 owing to development could not be completed on account of the end of the war. Special control devices would have given the A.9 at least the same accuracy as the A.4. It was proposed that the weapon should go into a vertical dive at the end of the glide, similar to that of the V.1.

As a further development, it was intended to design the A.9 winged rocket to carry a crew. For that purpose the rocket was to be equipped with a retracting undercarriage, a pressurized cabin for the pilot, manually operated steering gear for use when landing, and special aerodynamic aids to landing. The landing speed of this piloted A.9 rocket would have been as low as 160km per hour, as it would have contained very little fuel on landing, and would consequently have been light. This piloted A.9 rocket would cover a distance of 600km in approx. 17 minutes.

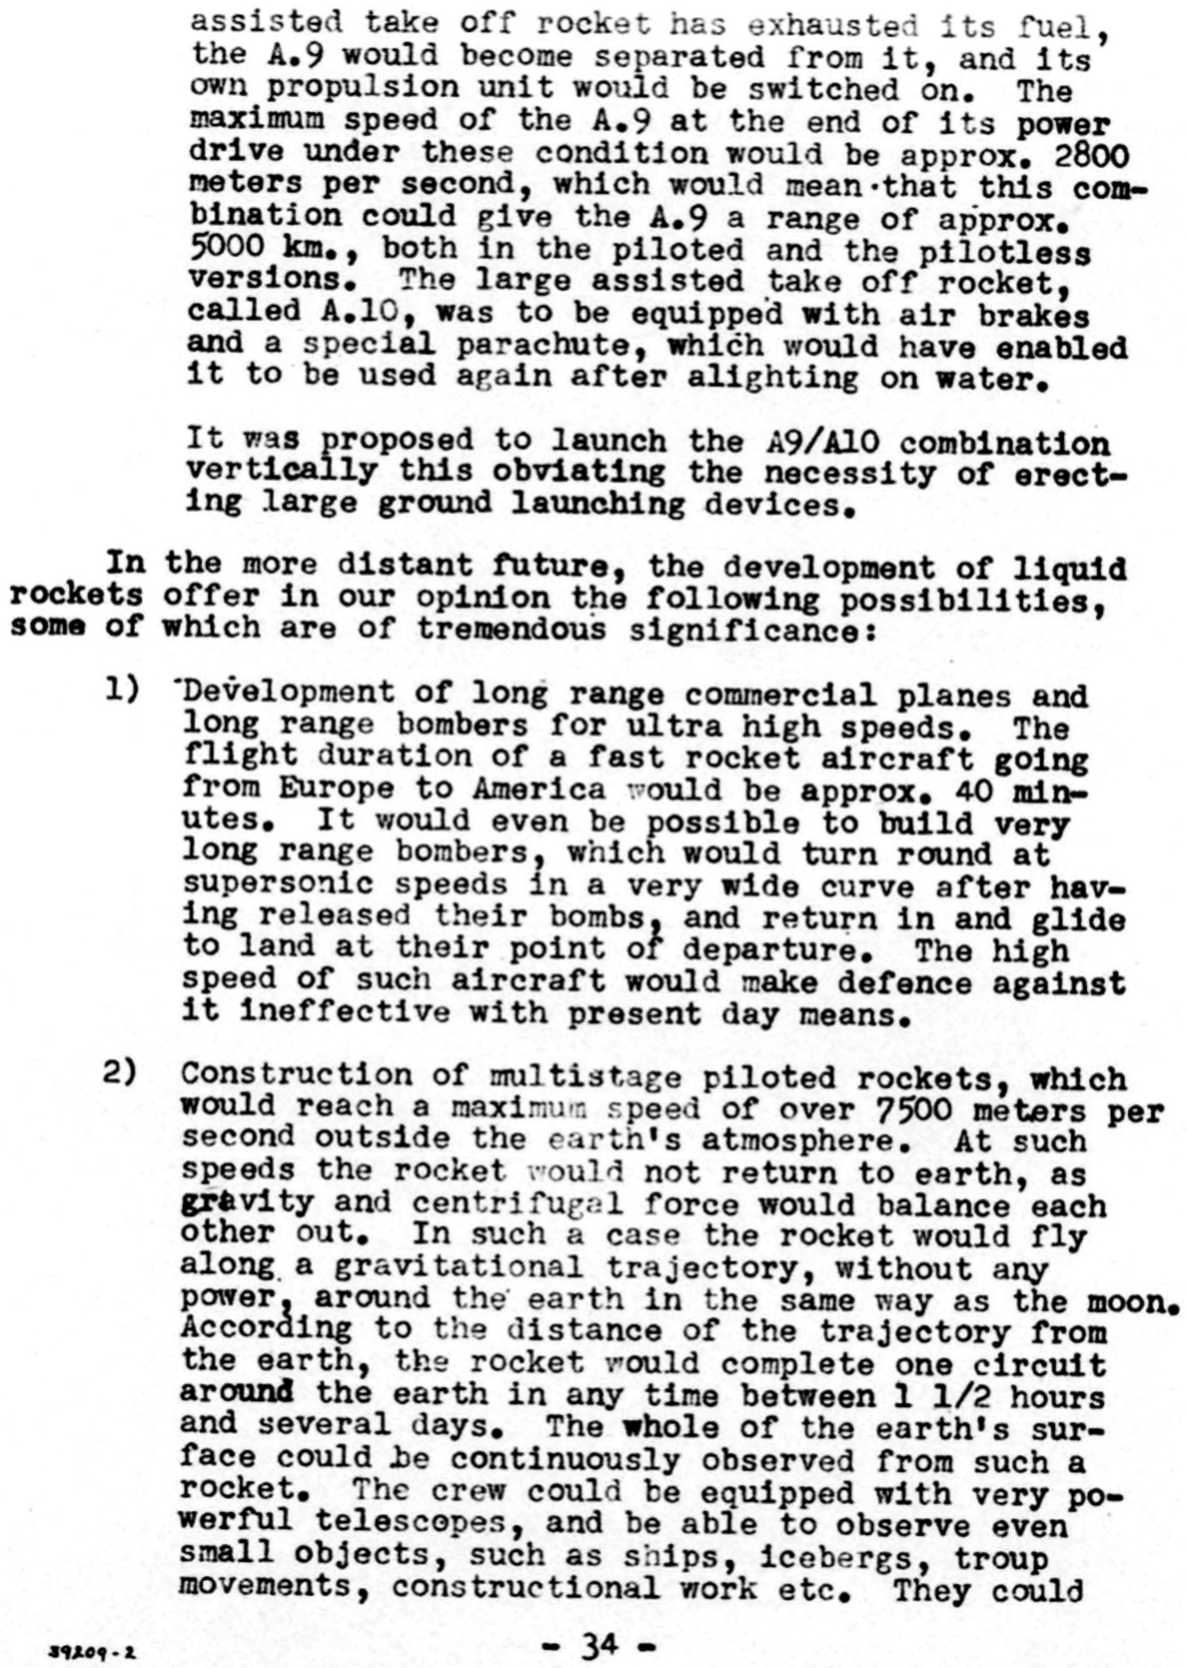
The range of the A.9, both in the piloted and the pilotless versions, could be increased considerably if the propulsion unit were switched on only after the rocket had attained a certain initial velocity. There were two possible ways of achieving this end.

1) Use of a long catapult with only a slight gradient, which would have given the rocket an initial velocity of approximately 350m/sec. There was experience of this type of catapult to hand at Peenemunde, as such a catapult developed by an industrial firm for launching the V.1, was tried out at Peenemunde. Experience showed that catapults could be built for launching at supersonic speed. These high speeds are essential for rockets such as A.9, because the rocket is completely filled with fuel at the start and would not fly if it left the catapult at lower speeds.

2) Development of a large assisted take off rocket of 200 tons thrust, on which the A.9 rocket would be mounted, and which would give the latter an initial velocity of 1200 meters per second. After the

39209-2 - 33 -

Figure E.120: CIOS XXVIII-56. *Rockets and Guided Missiles.*



assisted take off rocket has exhausted its fuel, the A.9 would become separated from it, and its own propulsion unit would be switched on. The maximum speed of the A.9 at the end of its power drive under these condition would be approx. 2800 meters per second, which would mean that this combination could give the A.9 a range of approx. 5000 km., both in the piloted and the pilotless versions. The large assisted take off rocket, called A.10, was to be equipped with air brakes and a special parachute, which would have enabled it to be used again after alighting on water.

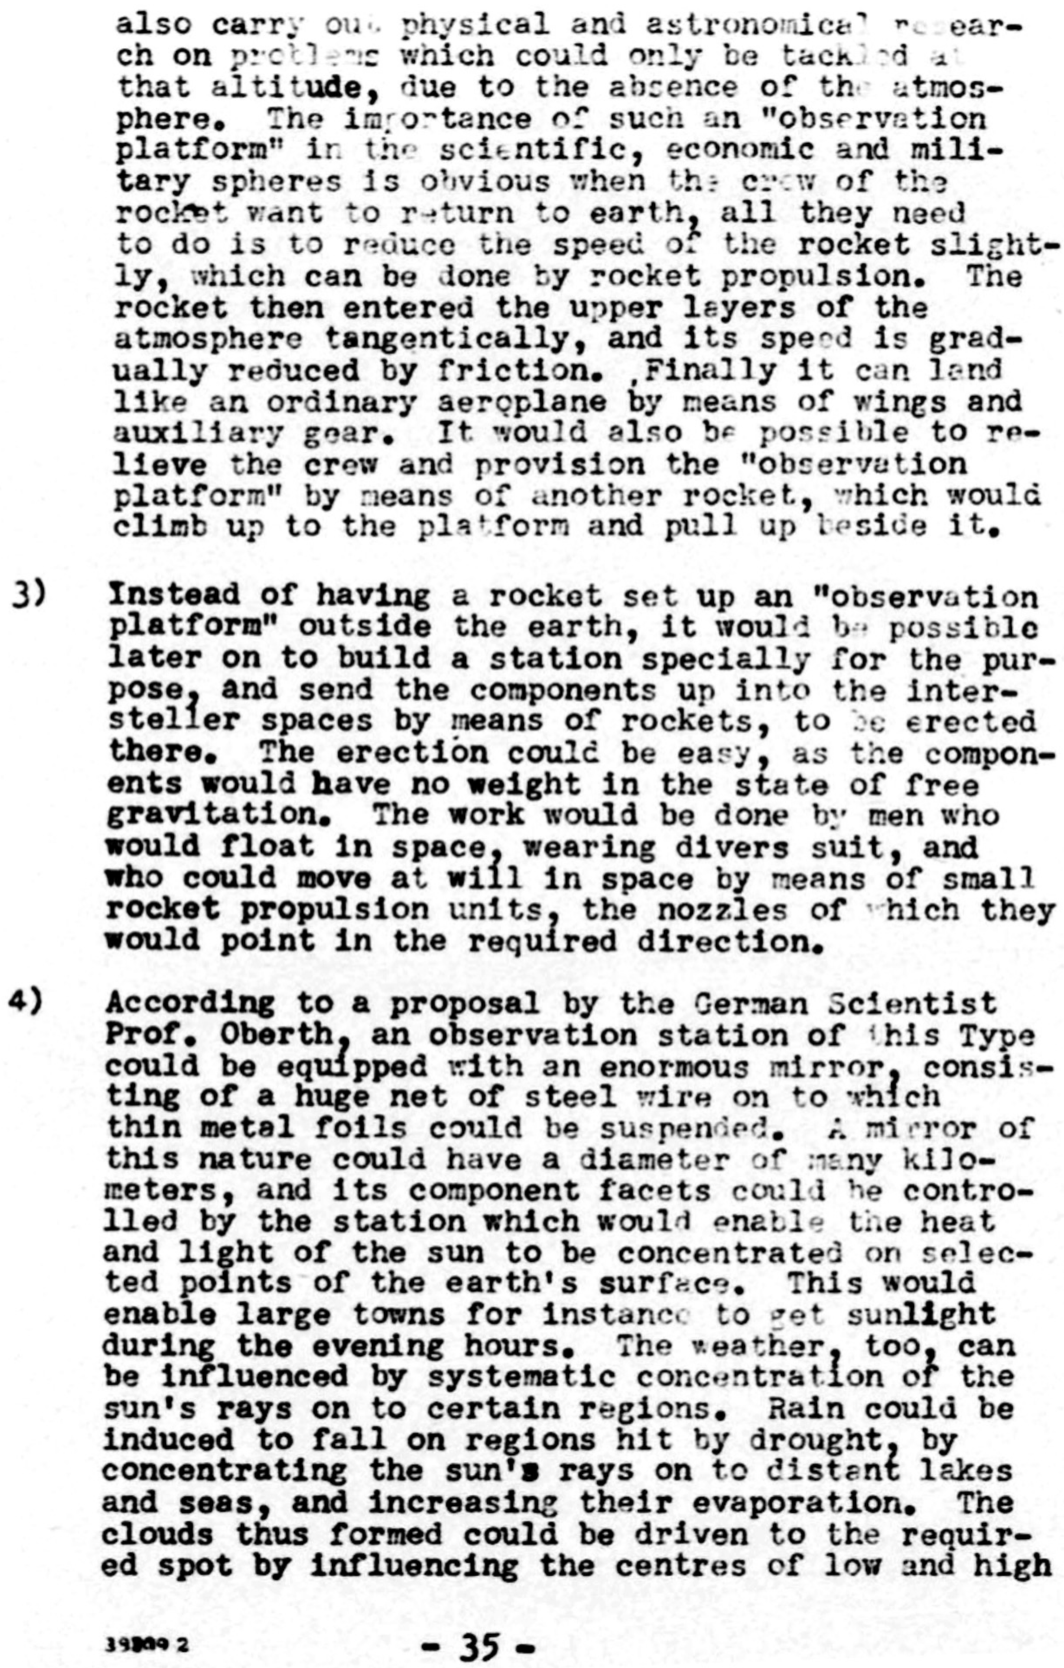
It was proposed to launch the A9/A10 combination vertically this obviating the necessity of erecting large ground launching devices.

In the more distant future, the development of liquid rockets offer in our opinion the following possibilities, some of which are of tremendous significance:

1) Development of long range commercial planes and long range bombers for ultra high speeds. The flight duration of a fast rocket aircraft going from Europe to America would be approx. 40 minutes. It would even be possible to build very long range bombers, which would turn round at supersonic speeds in a very wide curve after having released their bombs, and return in and glide to land at their point of departure. The high speed of such aircraft would make defence against it ineffective with present day means.

2) Construction of multistage piloted rockets, which would reach a maximum speed of over 7500 meters per second outside the earth's atmosphere. At such speeds the rocket would not return to earth, as gravity and centrifugal force would balance each other out. In such a case the rocket would fly along a gravitational trajectory, without any power, around the earth in the same way as the moon. According to the distance of the trajectory from the earth, the rocket would complete one circuit around the earth in any time between 1 1/2 hours and several days. The whole of the earth's surface could be continuously observed from such a rocket. The crew could be equipped with very powerful telescopes, and be able to observe even small objects, such as ships, icebergs, troup movements, constructional work etc. They could

Figure E.121: CIOS XXVIII-56. *Rockets and Guided Missiles.*



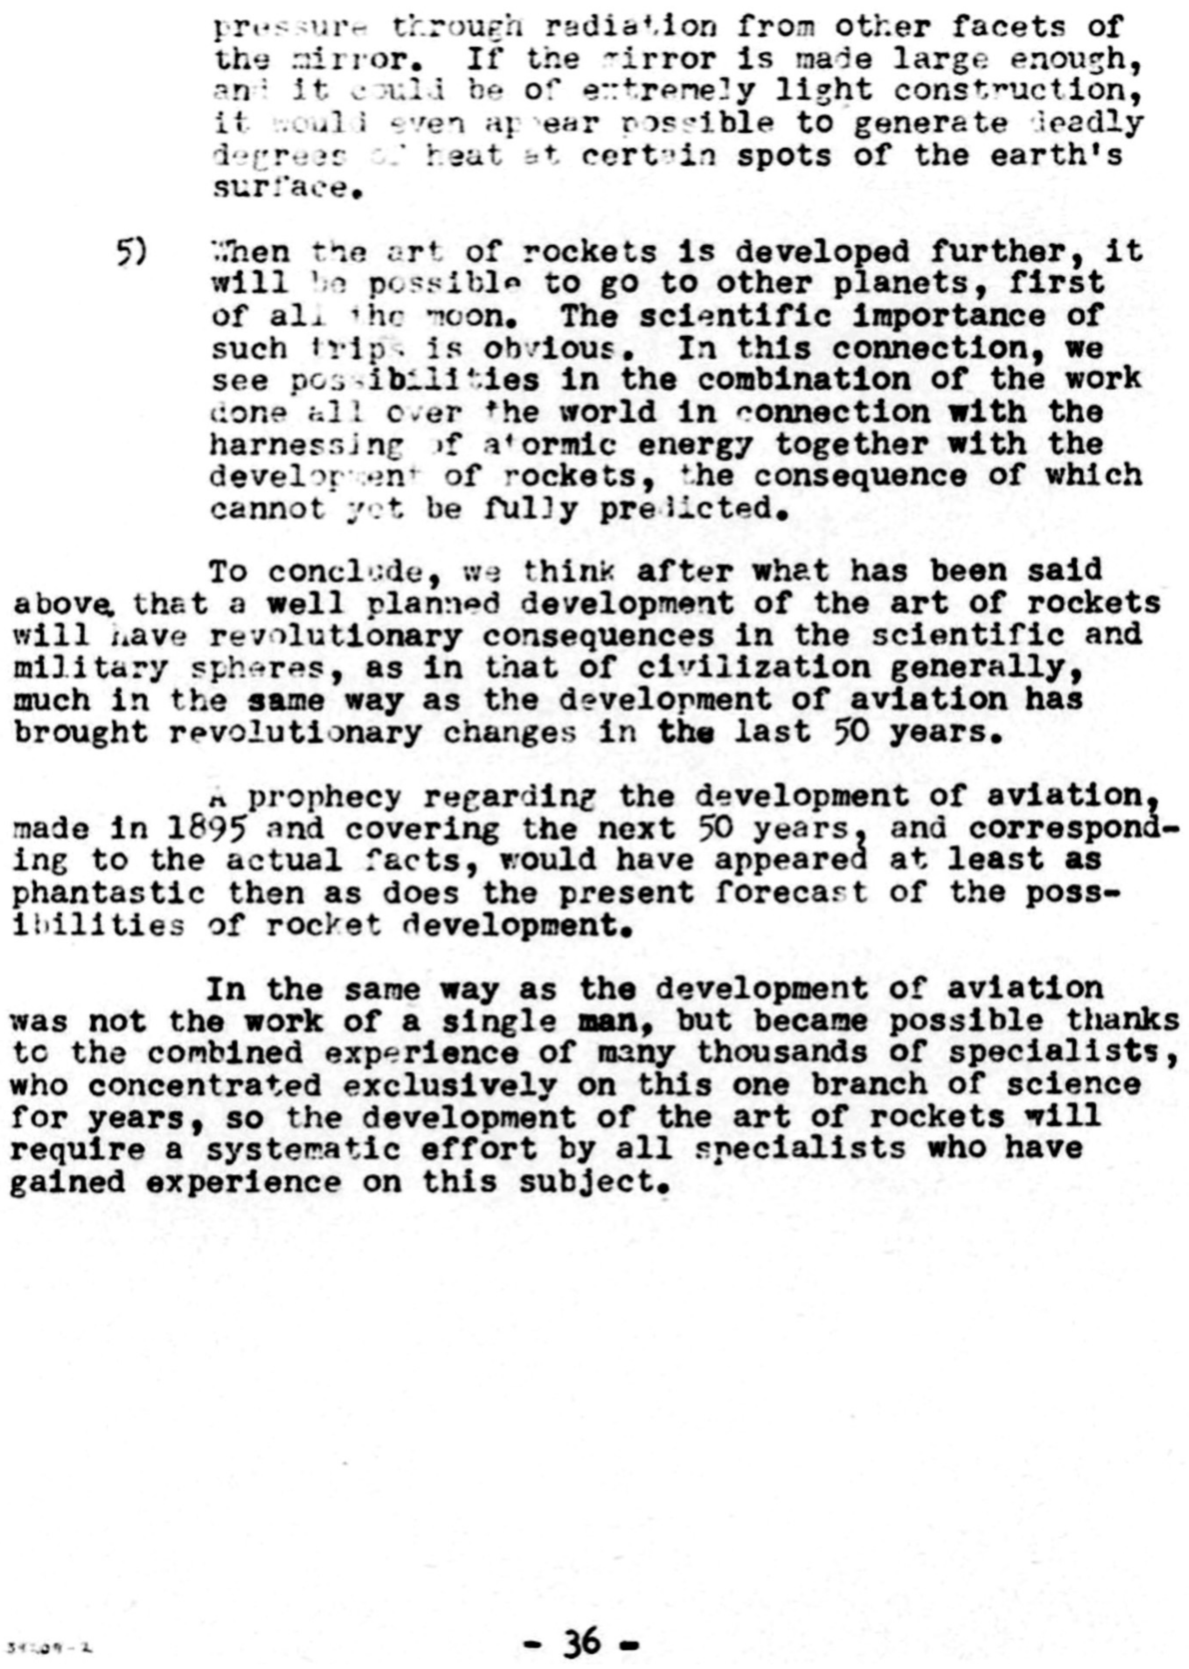
also carry out physical and astronomical research on problems which could only be tackled at that altitude, due to the absence of the atmosphere. The importance of such an "observation platform" in the scientific, economic and military spheres is obvious when the crew of the rocket want to return to earth, all they need to do is to reduce the speed of the rocket slightly, which can be done by rocket propulsion. The rocket then entered the upper layers of the atmosphere tangentically, and its speed is gradually reduced by friction. Finally it can land like an ordinary aeroplane by means of wings and auxiliary gear. It would also be possible to relieve the crew and provision the "observation platform" by means of another rocket, which would climb up to the platform and pull up beside it.

3) Instead of having a rocket set up an "observation platform" outside the earth, it would be possible later on to build a station specially for the purpose, and send the components up into the intersteller spaces by means of rockets, to be erected there. The erection could be easy, as the components would have no weight in the state of free gravitation. The work would be done by men who would float in space, wearing divers suit, and who could move at will in space by means of small rocket propulsion units, the nozzles of which they would point in the required direction.

4) According to a proposal by the German Scientist Prof. Oberth, an observation station of this Type could be equipped with an enormous mirror, consisting of a huge net of steel wire on to which thin metal foils could be suspended. A mirror of this nature could have a diameter of many kilometers, and its component facets could be controlled by the station which would enable the heat and light of the sun to be concentrated on selected points of the earth's surface. This would enable large towns for instance to get sunlight during the evening hours. The weather, too, can be influenced by systematic concentration of the sun's rays on to certain regions. Rain could be induced to fall on regions hit by drought, by concentrating the sun's rays on to distant lakes and seas, and increasing their evaporation. The clouds thus formed could be driven to the required spot by influencing the centres of low and high

39399 2 - 35 -

Figure E.122: CIOS XXVIII-56. *Rockets and Guided Missiles.*



pressure through radiation from other facets of the mirror. If the mirror is made large enough, and it could be of extremely light construction, it would even appear possible to generate deadly degrees of heat at certain spots of the earth's surface.

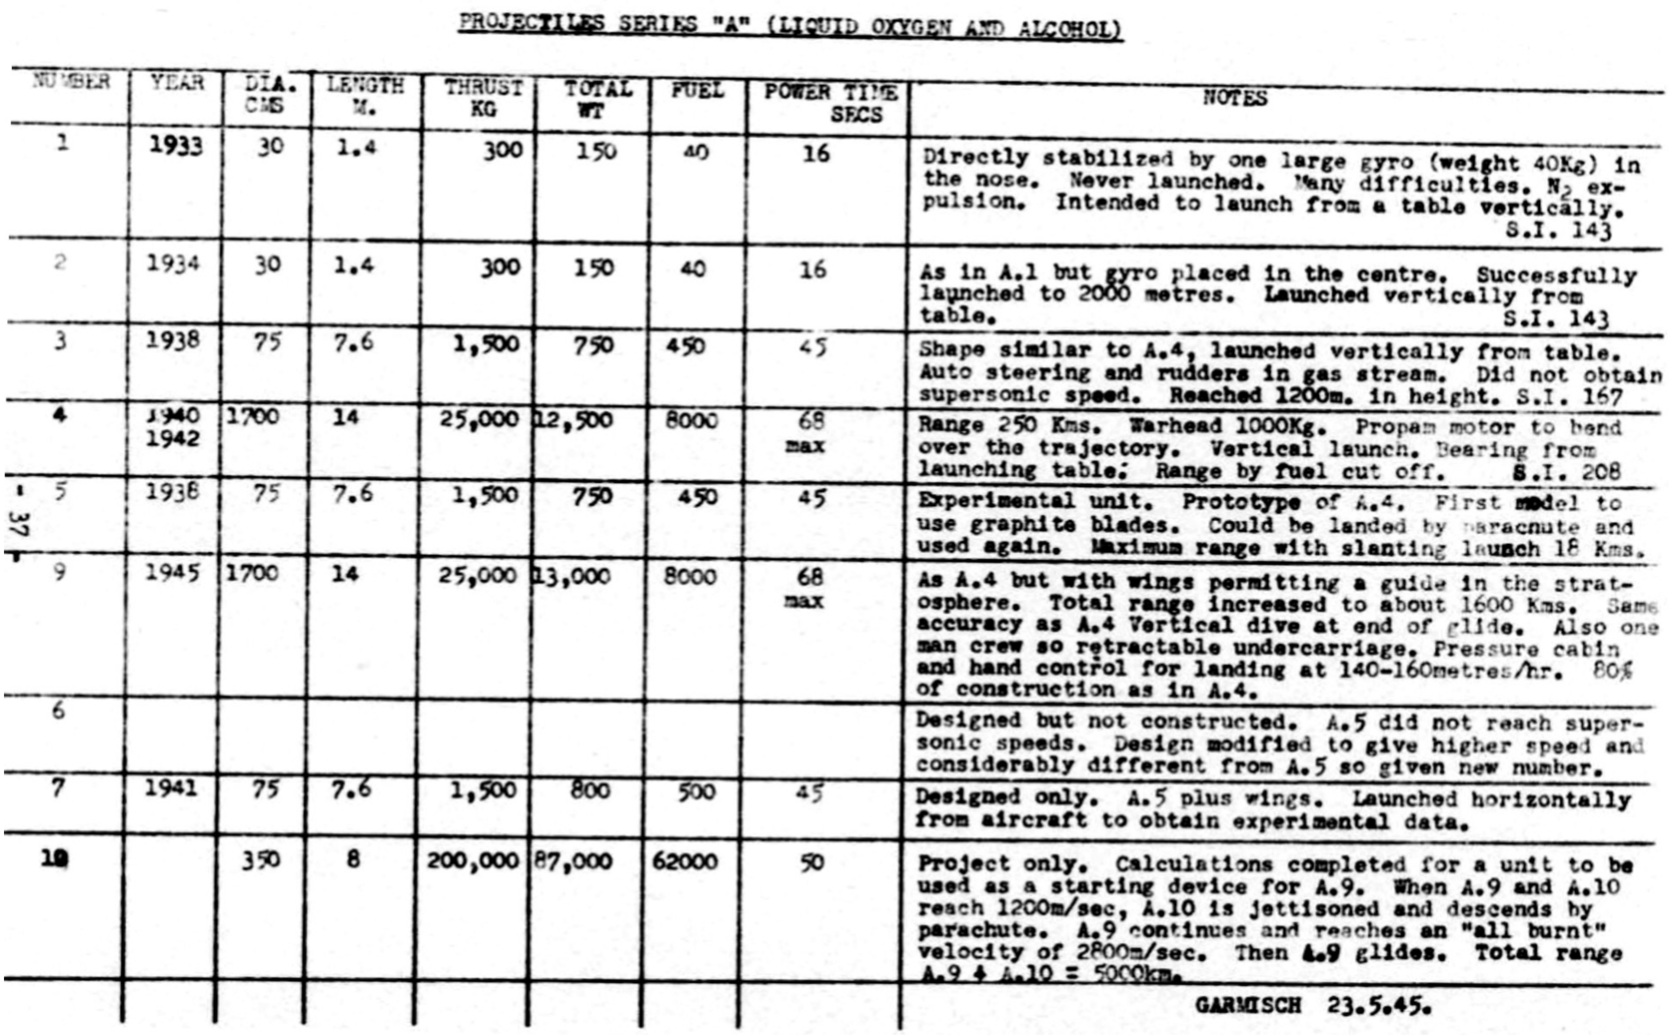
5) When the art of rockets is developed further, it will be possible to go to other planets, first of all the moon. The scientific importance of such trips is obvious. In this connection, we see possibilities in the combination of the work done all over the world in connection with the harnessing of atomic energy together with the development of rockets, the consequence of which cannot yet be fully predicted.

To conclude, we think after what has been said above, that a well planned development of the art of rockets will have revolutionary consequences in the scientific and military spheres, as in that of civilization generally, much in the same way as the development of aviation has brought revolutionary changes in the last 50 years.

A prophecy regarding the development of aviation, made in 1895 and covering the next 50 years, and corresponding to the actual facts, would have appeared at least as phantastic then as does the present forecast of the possibilities of rocket development.

In the same way as the development of aviation was not the work of a single man, but became possible thanks to the combined experience of many thousands of specialists, who concentrated exclusively on this one branch of science for years, so the development of the art of rockets will require a systematic effort by all specialists who have gained experience on this subject.

Figure E.123: CIOS XXVIII-56. *Rockets and Guided Missiles.*



PROJECTILES SERIES "A" (LIQUID OXYGEN AND ALCOHOL)

NUMBER	YEAR	DIA. CMS	LENGTH M.	THRUST KG	TOTAL WT	FUEL	POWER TIME SECS	NOTES
1	1933	30	1.4	300	150	40	16	Directly stabilized by one large gyro (weight 40Kg) in the nose. Never launched. Many difficulties. N_2 expulsion. Intended to launch from a table vertically. S.I. 143
2	1934	30	1.4	300	150	40	16	As in A.1 but gyro placed in the centre. Successfully launched to 2000 metres. Launched vertically from table. S.I. 143
3	1938	75	7.6	1,500	750	450	45	Shape similar to A.4, launched vertically from table. Auto steering and rudders in gas stream. Did not obtain supersonic speed. Reached 1200m. in height. S.I. 167
4	1940 1942	1700	14	25,000	12,500	8000	68 max	Range 250 Kms. Warhead 1000Kg. Propam motor to bend over the trajectory. Vertical launch. Bearing from launching table. Range by fuel cut off. S.I. 208
5	1938	75	7.6	1,500	750	450	45	Experimental unit. Prototype of A.4. First model to use graphite blades. Could be landed by parachute and used again. Maximum range with slanting launch 18 Kms.
9	1945	1700	14	25,000	13,000	8000	68 max	As A.4 but with wings permitting a guide in the stratosphere. Total range increased to about 1600 Kms. Same accuracy as A.4 Vertical dive at end of glide. Also one man crew so retractable undercarriage. Pressure cabin and hand control for landing at 140-160metres/hr. 80% of construction as in A.4.
6								Designed but not constructed. A.5 did not reach supersonic speeds. Design modified to give higher speed and considerably different from A.5 so given new number.
7	1941	75	7.6	1,500	800	500	45	Designed only. A.5 plus wings. Launched horizontally from aircraft to obtain experimental data.
10		350	8	200,000	87,000	62000	50	Project only. Calculations completed for a unit to be used as a starting device for A.9. When A.9 and A.10 reach 1200m/sec, A.10 is jettisoned and descends by parachute. A.9 continues and reaches an "all burnt" velocity of 2800m/sec. Then A.9 glides. Total range A.9 + A.10 = 5000km.

- 37 -

Figure E.124: CIOS XXVIII-56. *Rockets and Guided Missiles.*

NavTechMisEu 237-45. *Survey of German Activities in the Field of Guided Missiles.* August 1945. [NARA RG 38, Entry P5, Box 38]

[...] It must be borne in mind that the magnitude of the Germans' basic research program was tremendous and that it was equally thorough for all types of controlled missiles. Once they realized the defensive potentialities of various types of this new weapon, a program was inaugurated, which if given six more months uninterrupted time, might well have resulted in the achievement of what had become a basic policy: to drive bombers from the sky at altitudes below fifty thousand feet. [...]

The FX and Hs missiles were predicated on the assumption that the Luftwaffe would maintain air supremacy and while this condition existed they were used to good advantage. Contrary to popular idea, that the Allies succeeded in effectively jamming the radio control used in these missiles consequently arresting their use, the contributing evidence from enemy operational and developmental personnel is definitely negative. [...]

With the increase in Allied air power, Axis interest began to focus on the development of controlled anti-aircraft missiles. This interest grew rapidly and a highly competitive development program for AA missiles expanded with the steady increase of Allied aerial might until at one time in 1943 there were under development in Germany 48 different anti-aircraft missiles. [...] 12 were to be carried through to full development for operational use. [...]

The V-1 was the first long range missile operationally used as a self-controlled, non-piloted guided or controlled weapon. It is estimated that over 20,000 of these were used against the Allies. [...]

During this same period, the development of the A series, i.e., V-2 missiles, for supersonic speed ranges was carried on in spite of continual handicaps caused by Allied bombings. A large modern well-equipped missile development and testing center was established at Peenemünde on the Baltic Sea. This station which cost 300 million gold marks for the initial installation was started in 1936 and was reported in operation in 1937. [...] After the expenditure of a tremendous amount of money and energy on this project, the A-4 missile went into operational use in 1944. It is estimated that 3000–5000 of these missiles were built.

To increase range, the A-4b was made by the simple addition of wings to the A-4. This approximately doubled the A-4's range. With the ultimate operational range in sight for the A-4b, design work was immediately started on more radical weapons. There is little of humorous nature in the statements so often heard that the Germans intended to bombard New York from launching sites in Europe, as two missiles, the A-9 and A-10, were under development for use against the U.S. in the early months of 1946. This contemplated use was scientifically possible and undoubtedly would have been realized had time permitted.

The German guided missile program during the last stages of the war provided for development of every conceivable basic type, one classification of which follows:

(a) Surface launched to air targets.

(b) Air launched to air targets.

(c) Air launched to surface targets.

(d) Surface launched to surface targets.

(e) Underwater launched to underwater targets.

(f) Underwater launched to surface targets.

(g) Underwater launched to air targets.

Every known type of remote control, self-seeking or homing device, and proximity fuse was being developed or exploited for use in guided missiles. This included radio control, wire control, radar, continuous wave radio, acoustics, infra red, light beams, magnetics, etc. It was in this field, however, that the missile program was suffering the most serious difficulties.

All types of jet [rocket] propulsion were being incorporated into the power plants of the missiles which were being built to fly at speeds both subsonic and supersonic.

Work on the science of controlled missiles was being carried out in every area visited in Allied occupied territory, from the border of Denmark to Switzerland and from the coast of France to the Russian zone of occupation. It is a known fact that some work was being done in Denmark, Norway and Poland, and it is estimated that 50% of the total German effort in this field was in what is now Russian-occupied territory, to which investigators have not had access. The results of the enemy's guided missile work are evident on the targets in England, Belgium, and Holland.

It is estimated that one-third of the energy directed to aerodynamic research in Germany was devoted to the problems of guided missiles. The research laboratories at Braunschweig, Goettingen, Darmstadt, Ainring, etc., were involved in major projects and the above establishments have capacities exceeding anything previously dreamed of in America. There exists in Germany numerous wind tunnels with a Mach number of 4, i.e., four times the speed of sound. One tunnel with a Mach number of 10 was under construction. Some degree of guided missiles research was being carried out in all of the above tunnels.

It has been gratifying to find a few isolated items relating to the field of guided missiles in which the German product was inferior to similar accomplished in America. However, this is subject to being misconstrued if used to magnify our virtues or exonerate our failures by so-called experts who have "surveyed the field" in a few weeks, returned to America and announced they are disappointed to find the Germans have nothing to offer. Such a statement is evidence of the individual's refusal to accept the obvious fact, inexcusable if made in innocent though stupid sincerity, and criminal if made for ulterior motives.

From observation of the enemy's work, it is concluded that:

(a) If given a relatively short period of time, Germany would have succeeded in bringing into the war an effective counter measure against aerial bombers. She would have produced infinitely superior assault weapons through intensive exploitation of the science of guided missiles.

(b) From the standpoint of future warfare, the work of the Peenemünde and associated groups without question ranked among the most important being done in Germany on any subject. Although the apparent results of this organization have been extensively covered by investigators, determination of the group's ultimate goal remains an assumption based on the trend of their developments. Undoubtedly they expected to produce weapons from the A series with which they could accurately hit any area on the face of the earth. It is equally obvious that with the V-2 they were not only working out in advance the aerodynamic and control problems of such weapons, but that in the present weapon they had a proven vehicle ready to receive whatever radically new explosive and propulsive substance they expected to become available. It is inconceivable that the V-2 was considered by the German scientists to be an end in itself, nor that with all its complexities, it was developed at the cost of billions of dollars and manufactured in great quantity with highest priority merely to deposit 750 kilograms of ordinary explosive on British territory.

With the relaxation to a practical degree of the impenetrable screen that has surrounded the investigation of German atomic disintegration research, some of the hitherto inexplicables of their guided missile program are now subject to an analysis from which reasonable answers can be derived. It is now obvious that Germans realized and have accepted for years the fact that a controlled missile is the natural vehicle with which to transport atomic explosive. At last, the reasoning behind the design specifications which provided for very small warheads and the invariable orders to terminate missile projects upon completion of development are no longer mysteries or absurdities. [...]

[NavTechMisEu 237-45 is over 450 pages long, with concise yet informative sections on most German rockets and missiles that were developed or under development. What is quoted above and shown on pp. 5432–5437 is just the introduction.

Further Allied investigations appear to have confirmed the conclusions of NavTechMisEu 237-45. In fact, the introduction of NavTechMisEu 237-45 was deemed worthy of being repeated almost verbatim in:

H. H. Smith, N. W. Dickson, V. P. Kovac, and E. H. Bennett. 10 January 1946. German Developments in the Guided Missile Field. Project 2874. [NARA RG 319, Entry NM3-82, Box 2879, Folder Project 2784]]

CONFIDENTIAL

Part 1

INTRODUCTION

Although the Germans recognized the potentialities of remotely controlled missiles during World War I and accepted them without equivocation as a military weapon over ten years ago, the science did not assume its current degree of exceptional importance to them until the latter stages of the recent conflict. When the necessity of stopping the Allied bombers became paramount, it was realized that the answer lay in Guided Missiles.

Germany, contrary to the reasoning of other countries, had not in any sense failed to lay the groundwork of fundamental research for producing a complete series of potentially satisfactory anti-aircraft controlled missiles; however, the basic work did not manifest itself as usable "flak" because the actual construction and experimental testing were neglected until too late. It is obvious now that the foregoing resulted from underestimation of the damage the Allied air forces could inflict, from a misconstrued confidence in their standard counter weapons which were even then obsolete, and from overconfidence in the damage, both physical and psychological, which their V-weapons were effecting.

It is interesting to note that it was the ground-to-ground self controlled missile, i.e., the V-weapon, which was selected to receive the lion's share of the energy devoted to testing and developing of guided missiles. Even in minds chained to the utility of conventional weapons, the obvious strategical employment of this type could not be overlooked. However, in selecting what at that time must have appeared to them a fantastic innovation, they did not recognize the implications pointing to related weapons which were to become vitally important.

It must be borne in mind that the magnitude of the Germans' basic research program was tremendous and that it was equally thorough for all types of controlled missiles. Once they realized the defensive potentialities of various types of this new weapon, a program was inaugurated, which if given six more months uninterrupted time, might well have resulted in the achievement of what had become a basic policy: to drive bombers from the sky at altitudes below fifty thousand feet.

In justification of the above, the picture of the history and magnitude of German effort in this field is included. The idea of

Introduction (Cont'd.)

increasing the accuracy of a weapon by controlling it to its target was conceived during the first World War. This thought manifested itself in the form of an aerial bomb guided in range and azimuth by signals transmitted down a wire which unreeled as the missile fell. Projects related to the above lay dormant until World War II, when the modern controlled missile program made its appearance in the form of the FX high angle bomb and the Hs glide bomb series in the Mediterranean. However, the intervening time was not wasted, as it was during this period between wars that the experimental rocket groups were most active. One faction of these groups later formed the nucleus of the Peenemunde personnel.

The FX and Hs missiles were predicated on the assumption that the Luftwaffe would maintain air supremacy and while this condition existed they were used to good advantage. Contrary to popular idea, that the Allies succeeded in effectively jamming the radio control used in these missiles consequently arresting their use, the contributing evidence from enemy operational and developmental personnel is definitely negative. It appears that a routine strike against an airport by Allied airmen had the good fortune of unknowingly destroying all enemy aircraft modified to carry the missiles, and that by the time new planes could be made available, the fuel shortage had effectively put the Luftwaffe out of operation. Our radio jamming activities are said to have been effective on one channel of one frequency. The effort did not put an end to the use of Strassburg-Kiel radio control unit, but it did succeed in stimulating the enemy's thought and subsequent development activities relative to new control systems. Their first reaction was the return to the wire control method of transmitting intelligence. This was closely followed by programs designed to cover all eventualities.

With the increase in Allied air power, Axis interest began to focus on the development of controlled anti-aircraft missiles. This interest grew rapidly and a highly competitive development program for AA missiles expanded with the steady increase of Allied aerial might until at one time in 1943 there were under development in Germany 48 different anti-aircraft missiles. To counteract the increasing abuse Allied air power was delivering to German industry, it was necessary to streamline the program to produce greater emphasis and efficiency. Therefore, the 48 different anti-aircraft development projects were surveyed and after an analysis as to completion of development and effectiveness of the missiles, all but 12 of the 48 were discontinued. The remaining 12 were to be carried through to full development for operational use.

Introduction (Cont'd.)

During the period of growth of the Allied air power, the heretofore visualized need of long range remote controlled or self controlled missiles for area bombing became an actual necessity. Resulting from the successive defeats, the Luftwaffe was suffering, it became less and less advisable to send bombing squadrons against the enemy; therefore, increased effort was placed on the development of supersonic missiles which were visualized as early as 1936 as potential weapons. These were hastily and prematurely thrown into the fray. In addition to the development of long range supersonic weapons, there was simultaneously carried out through developmental to operational use, the V-1 weapn or "buzz-bomb". The V-1 was the first long range missile operationally used as a self-contained, non-piloted guided or controlled weapon. It is estimated that over 20,000 of these were used against the Allies.

As a substitute for the V-1, the BV series of glide bombs were developed as an inexpensive long range (100 miles) bomb for area bombing. Approximately 400 of these were built and tested, but they were never put to operational use due to a shortage of suitable bombers to carry and launch them.

During this same period, the development of the A series, i.e., V-2 missiles, for supersonic speed ranges was carried on in spite of continual handicaps caused by Allied bombings. A large modern well-equipped missile development and testing center was established at Peenemunde on the Baltic Sea. This station which cost 300 million gold marks for the initial installation was started in 1936 and was reported in operation in 1937. Regardless of Peenemunde's tremendous size and its influence on the program, it in no way portrays the extent of the energy being exerted by other governmental agencies and commercial firms within the Reich. After the expenditure of a tremendous amount of money and energy on this project, the A-4 missile went into operational use in 1944. It is estimated that 3000-5000 of these missiles were built.

To increase range, the A-4b was made by the simple addition of wings to the A-4. This approximately doubled the A-4's range. With the ultimate operational range in sight for the A-4b, design work was immediately started on more radical weapons. There is little of humorous nature in the statements so often heard that the Germans intended to bombard New York from launching sites in Europe, as two missiles, (the A-9) and (A-10, were under development for use against the U.S. in the early months of 1946. This contemplated use was scientifically possible and undoubtedly would

Introduction (Cont'd.)

have been realized has time permitted.

The German guided missile program during the last stages of the war provided for development of every conceivable basic type, one classification of which follows:

(a) Surface launched to air targets.

(b) Air launched to air targets.

(c) Air launched to surface targets.

(d) Surface launched to surface targets.

(e) Underwater launched to underwater targets.

(f) Underwater launched to surface targets.

(g) Underwater launched to air targets.

Every known type of remote control, self-seeking or homing device, and proximity fuze was being developed or exploited for use in guided missiles. This included radio control, wire control, radar, continuous wave radio, acoustics, infra red, light beams, magnetics, etc. It was in this field, however, that the missile program was suffering the most serious difficulties.

All types of jet propulsion were being incorporated into the power plants of the missiles which were being built to fly at speeds both subsonic and supersonic.

Work on the science of controlled missiles was being carried out in every area visited in Allied occupied territory, from the border of Denmark to Switzerland and from the coast of France to the Russian zone of occupation. It is a known fact that some work was being done in Denmark, Norway and Poland, and it is estimated that 50% of the total German effort in this field was in what is now Russian-occupied territory, to which investigators have not had access. The results of the enemy's guided missile work are evident on the targets in England, Belgium and Holland.

It is estimated that one-third of the energy directed to aerodynamic

Introduction (Cont'd.)

research in Germany was devoted to the problems of guided missiles. The research laboratories at Braunschweig, Goettingen, Darmstadt, Ainring, etc., were involved in major projects and the above establishments have capacities exceeding anything previously dreamed of in America. There exists in Germany numerous wind tunnels with a Mach number of 4, i.e., four times the speed of sound. One tunnel with a Mach number of 10 was under construction. Some degree of guided missiles research was being carried out in all of the above tunnels.

It has been gratifying to find a few isolated items relating to the field of guided missiles in which the German product was inferior to similar accomplished in America. However, this is subject to being misconstrued if used to magnify our virtues or exonerate our failures by so-called experts who have "surveyed the field" in a few weeks, returned to America and announced they are disappointed to find the Germans have nothing to offer. Such a statement is evidence of the individual's refusal to accept the obvious fact, inexcusable if made in innocent though stupid sincerity, and criminal if made for ulterior motives.

From observation of the enemy's work, it is concluded that:

(a) If given a relatively short period of time, Germany would have succeeded in bringing into the war an effective counter measure against aerial bombers. She would have produced infinitely superior assault weapons through intensive exploitation of the science of guided missiles;

(b) From the standpoint of future warfare, the work of the Peenemunde and associated groups without question ranked among the most important being done in Germany on any subject. Although the apparent results of this organization have been extensively covered by investigators, determination of the groups' ultimate goal remains an assumption based on the trend of their developments. Undoubtedly they expected to produce weapons from the A series with which they could accurately hit any area on the face of the earth. It is equally obvious that with the V-2 they were not only working out in advance the aerodynamic and control problems of such weapons, but that in the present weapon they had a proven vehicle ready to receive whatever radically new explosive and propulsive substance they expected to become available. It is inconveivable that the V-2 was considered by the German scientists to be an end in itself, nor that with all its complexities, it was developed at the cost of billions of dollars and manufactured in great quantity with highest priority merely to deposit

Introduction (Cont'd.)

750 kilograms of ordinary explosive on British territory.

With the relaxation to a practival degree of the impenetrable screen that has surrounded the investigation of German atomic disintegration research, some of the hitherto inexplicables of their guided missile program are now subject to an analysis from which reasonable answers can be derived. It is now obvious that the Germans realized and have accepted for years the fact that a controlled missile is the natural vehicle with which to transport atomic explosive. At last, the reasoning behind the design specifications which provided for very small warheads and the invariable orders to terminate missile projects upon completion of development are no longer mysteries or absurdities.

(c) There existed in Germany no guided missile project which would warrant exact duplication with the expectation of using it as a practical weapon by the Allies. However, the knowledge we can gain from intensive sudy of their progress is infinite. Therefore, serious consideration should be given to the practicability of producing a limited number of representative German types to be used in a development and operational educational program conceived to bring the Allies abreast of the field.

(d) If in any country the development of the weapons with which to fight a future war is, as it has been in the past, dependent only on the impetus of the war for support, that country when attacked will not survive the first operation!

-7-

Theodore von Kármán. *Where We Stand.* 22 August 1945 [von Kármán 1945].

The present war started on both sides with "conventional" weapons and equipment; "conventional" because their principles of action, design, and performance were fundamentally known to the enemy. During the war both sides produced equipment and weapons of astonishing effects which will certainly change the whole picture of future aerial warfare.

This report is concerned with the main fields in which significant advances have been made and tries to show "where we stand" with some indications as to "where we shall go."

For future planning of research and development, the following new aspects of aerial warfare have to be considered as fundamental realities:

1. that aircraft—manned or pilotless—will move with speeds far beyond the velocity of sound;

2. that due to improvements in aerodynamics, propulsion and electronic control, unmanned devices will transport means of destruction to targets at distances up to several thousand miles;

3. that small amounts of explosive materials will cause destruction over areas of several square miles;

4. that defense against present-day aircraft will be perfected by target seeking missiles;

5. that only aircraft or missiles moving at extreme speeds will be able to penetrate enemy territory protected by such defenses;

6. that a perfect communication system between fighter command and each individual aircraft will be established;

7. that location and observation of targets, take-off, navigation and landing of aircraft, and communication will be independent of visibility and weather;

8. that fully equipped airborne task forces will be enabled to strike at far distant points and will be supplied by air. [...]

German Development of Guided Missiles and Pilotless Aircraft [...]

Dr. von Braun, leader of the Peenemünde group which developed the V-2, was a student of Professor Hermann Oberth, a well-known inventor and writer in the field of rockets, who had published books on interplanetary rocket travel. A group of Oberth's students became interested in rockets and organized an amateur rocket group. All were well-trained scientists. In 1935, Dr. von Braun was employed by the German War Department and sent to Peenemünde. In 1941, von Braun brought Oberth there as head of the Patent Section. By 1941, Peenemünde was an active test station. The Me-163 was brought there in September, 1941 and in October, 1941 flew at a speed of 1,003 km hr (about 623 mph). In October, 1941, the first supersonic wind-tunnel tests were made on a projectile at a Mach number of 4.4. After the bombing of Peenemünde in August, 1943, the activities were decentralized. The wind-tunnel group went to Kochel, where it was in operation in January, 1944. The first use of the V-2 was on 8 September 1944. [...]

The German military agencies, research institutions, and industrial designers devoted a large effort to guided missiles and considered them very promising weapons. In August, 1944, there were some 25 projects for homing devices under developments. The major research laboratories of the air and ground forces made many wind-tunnel and flight tests, some at high supersonic speeds, and made many theoretical studies of problems related to guided missiles and pilotless aircraft (Fig. 6).

Looking over the great variety of projects one finds that the V-2 rocket was the most outstanding technical achievement and that the Peenemünde group of scientists, working for the ground forces, was the most capable missile research group in Germany. It is important for us to note that one element in their success was the fact that they had under a single leadership in one organization, experts in aerodynamics, structural design, electronics, servomechanisms, gyros and control devices, and propulsion; in fact, every group required for the development of a complete missile. The letters and papers in the files of industrial groups, like Messerschmitt, show rapid progress in the field of vehicle and propulsion, the fields in which the firm itself had qualified people, but delay after delay on controls and electronic devices which had to be secured elsewhere. The Luftwaffe research laboratories made little progress in the actual development of specific weapons, largely because of the absence of electronics experts and their lack of facilities for the construction of experimental missiles.

In addition to the German view that the final guided missile would be completely automatic in operation, the possibilities of long-range strategic bombing were fully understood. There is no question but that the diversion of the efforts of the Peenemünde scientists in 1943 to the development of an antiaircraft guided rocket delayed the introduction of the winged V-2 rocket (A-9) and its successor, the transoceanic rocket (A-9 plus A-10). Drawings and computations had been completed for the A-10, a rocket weighing 85 T with a thrust of 200 T to be used as a launching rocket for the A-9, accelerating it to a speed of 3,600 ft/sec. The motor of the A-9 would accelerate it further to a speed of 8,600 ft./sec, giving it a range of about 3,000 miles. Some consideration was given to the design of one version of the A-9 carrying a pilot. The Scientific Advisory Group agrees that the German results of wind-tunnel tests, ballistic computation, and experience with the V-2 justify the conclusion that a transoceanic rocket can be developed.

The principal German advantage in the field of guided missiles was the lead in time in the development of rockets, which were considered to have serious military applications as early as 1935. Much effort was put into this field and as a result the supporting industrial developments were ready as a foundation for missile designers. They could buy rocket motors and rocket fuels from commercial sources. In this respect they lead us. The V-2 development was successful not so much because of striking scientific developments as because of an early start, military support, and a boldness of execution. In the electronic field, radar in particular, we are definitely one or two years in the lead, although we have not put as much effort in the experimental determination of the limits of application of acoustic and infrared devices. [...]

However, beyond that the implications of the accomplishments of the German Peenemünde group and of the recent development of the atomic bomb by United States and British scientists, future methods of aerial warfare call for a reconsideration of all present plans. A part, if not all, of the functions of the manned strategic bomber in destroying the key industries, the communication and transportation systems, and military installations at ranges of from 1,000 to 10,000 miles will be taken over by the pilotless aircraft of extreme velocity. The use of supersonic speeds greatly reduces errors due to wind drift and other atmospheric conditions and the tremendous zone of damage of the atomic bomb diminishes the required precision. Hence, the difficult control problem is made easier.

For the future long-range strategic bomber, the Scientific Advisory Group foresees two types of pilotless aircraft, both with wings, one with a high trajectory reaching far into the outer atmosphere, and the other designed for level flight at high altitudes. The first one can be considered as a further development of the V-2 rocket. In fact, this was planned by the German scientists. By using two or more step-rockets for the acceleration, a very high speed is imparted to a missile, perhaps as high as 17,000 mph or more, to give ranges of several thousand miles. In this case, the wings are required mainly for control purposes, but they also serve to extend the glide path in the lower atmosphere. The German scientists have suggested a second type of trajectory requiring less initial energy, in which the wings are caused to curve the path of the missile when it returns to the region of increasing air density so that it rebounds to great heights. After a number of rebounds the winged missile settles down to a steady glide. Such a trajectory would seem difficult to control accurately (Fig. 8).

The second future strategic bomber is a supersonic pilotless aircraft, flying at altitudes of from 20,000 to say, 60,000 ft. It appears to us now that the speed will be about twice the speed of sound and that the aircraft will be powered by a turbojet motor. An intermediate step might be a pilotless aircraft traveling at high subsonic speeds with a Mach number of about 0.9 about 600 mph at 40,000 ft (Fig. 9). [...]

Leadership in the development of these new weapons of the future can be assured only by uniting experts in aero-dynamics, structural design, electronics, servo-mechanisms, gyros, control devices, propulsion, and warhead under one leadership, and providing them with facilities for laboratory and model shop production in their specialties and with facilities for field tests. Such a center must be adequately supported by the highest ranking military and civilian leadership and must be adequately financed, including the support of related work on special aspects of various problems at other laboratories and the support of special industrial developments. It seems to us that this is the lesson to be learned from the activities of the German Peenemünde group. [...]

Problems of Organization

The following problems relating to the long range research and development program of the Air Forces deserve consideration:

1. Scientific Planning: It is necessary that the Commanding General of the Air Forces and the Air Staff be advised continuously on the progress of scientific research and development in view of the potentialities of new discoveries and improvements in aerial warfare. A permanent Scientific Advisory Group, consisting of qualified officers and eminent civilian scientific consultants, should be available to the Commanding General, reporting directly to him on novel developments and advising him on the planning of scientific research. The scientific material collected by the organizations for military intelligence (G-2 and A-2) should be made available to this group for evaluation. Correspondingly, the scientific branch of G-2 and A-2 should be greatly strengthened by qualified personnel and facilities.

2. Research and Development within the Air Forces: It is necessary to organize a broad training program for officers in scientific and engineering fields, not merely to impart information on scientific and technical matters but to accustom them to working in cooperation with scientific institutions and scientists. [...]

3. Securing the Interest and Collaboration of Scientific Institutions and Individual Scientists: The Air Force should have access to the best qualified scientific talent and the best equipped laboratories of the nation for collaboration on their problems.

Experimental investigations desired by the scientific leaders the Air Forces to be carried out in any laboratory should be obtained by direct contract for the services desired.

Forrestal Urges Arms Inventions. ***New York Times*** **29 August 1945 p. 10.**

At the time of her defeat Germany had almost perfected a submarine that could stay under water virtually indefinitely and a "spider" torpedo that could be guided by a thin wire attached to its firing point, Secretary of the Navy James Forrestal revealed today. Germany was also far ahead of the Allies in many phases of experimentation with speeds faster than sound, he said.

He also disclosed that Germany was feeding technical information to Japan "to keep us as busy as possible in the Pacific." Thus, although he did not mention atomic-bomb experiments, it is possible that Germany either forwarded or tried to forward to Japan whatever information she could develop on the splitting of the atom, since Germany was competing with the United States in this field.

Predicting that, "if, unhappily, there should be another war, it would be fought with fantastically new weapons," Mr. Forrestal urged that the United States stay awake in the field of military research, even to the extent of creating actual models of new weapons.

Germans "Six Months Too Late"

"In general," he declared, "it may be said that the Germans were about six months too late in the development and mass production of new weapons. If in the future some maniac has delusions of world empire, he will start where the Germans left off. For our own defense and for the future peace of the world, it behooves us to continue research in military subjects so that no such maniac can ever feel that he has monopolized an advanced weapon which will put the world in general and the United States in particular at his mercy."

"For that reason I again urge the necessity of a substantial and alert post-war research program in military fields—and this research should be carried through to the actual production of pilot models"

Mr. Forrestal reported that the Germans had used submarines to transmit technical information to Japan, sometimes sending technicians to help the Japanese.

Foe's Submarines Better

He disclosed that, on his inspection trip to Europe between July 26 and Aug. 7, he had investigated the work of the Naval Technical Mission, composed of naval and civilian experts who had followed in the tracks of the invasion and occupation armies gathering useful German technical knowledge. He indicated that Germany had developed a submarine superior in many respects to ours despite previous statements made during the war by some of our naval officers who insisted that our submarines were the finest.

Mr. Forrestal said that present-day submarines might properly be described as submersibles—vessels that can submerge but must spend most of their time on the surface. The Germans, however, were developing a "true submarine" that "would almost never operate on the surface of the sea," and they had achieved "considerable success." [...]

"This submarine, known as Model 21, was capable of traveling under water at eighteen knots. That speed is markedly faster than any previously known craft had attained under the sea and was four knots faster than the Model 21 itself could do on the surface. It could not sustain this very high speed for much over an hour, but the Germans had in advanced states of development new propulsion methods which would have permitted even higher under-water speeds for much longer periods." [...]

Mr. Forrestal said that the Germans had had in development "at least two or three rockets which represented advances over what we call V-2." [...]

German experimentation with supersonic speed was carefully studied, he continued. To perfect the V-2, which had a speed far faster than sounds, and other weapons, the Germans had developed wind tunnels "far in advance of any we have in this country." In these tunnels, the Germans reproduced conditions existing at supersonic speed and tested devices to travel under such extreme conditions.

Nazi Secrets Given Japan to Use on U.S. *Washington Post.* 29 August 1945 p. 3.

The Germans were within six months of mass production of new weapons of great destruction when VE-Day closed their laboratories and shut off their production lines, Naval Secretary Forrestal disclosed yesterday.

His description of specific Nazi projects—new submarines, torpedoes, rockets, fuel—indicates that it was a scientists' race almost to the end.

Forrestal did not mention the Germans' atomic bomb work, but indicated they had a substantial lead over American scientists in many other fields. [...]

Gave Japs Information

Germany, Forrestal said, gave her technical information to Japan to keep us busy in the Pacific. He revealed that some German technicians said they had made the round trip to Japan by submarine.

This explained one reason for our Navy's concern over Japan's still-powerful sub fleet in the closing months of the war. It is known the Germans also passed on their electronics secrets.

The larger German subs could make the trip to Japan without refueling.

The naval secretary based his report on a trip to Europe, during which he observed the work of the Naval Technical Mission. These experts also discovered that the enemy had:

1. "The Spider," a torpedo always connected to its firing point by a thin wire spun out behind it. Through impulses sent over the wire, the missile could be made to change its course or depth, "even make it jump out of the water like a porpoise." This was intended for shore defense and, as far as is known, never was adapted to ships or submarines.

Were Developing Better Rockets

2. In the development stage at least two or three rockets better than the V2, which were to be mass-produced in large underground factories.

3. Devices [gas turbine engines] to control and use steam in some cases at double the pressure and temperature our high-pressure, high-temperature propulsion machinery can handle.

4. Developed a method for using hydrogen peroxide as a fuel, "with what looked like surprisingly good results" for the powering of naval units. Its first known use was in launching V-1 rockets and the auxiliary pumps for the V-2s.

5. Wind-tunnels "far in advance of any we have in this country" to promote basic research in supersonic speeds. In them they could simulate supersonic speed conditions and thus experiment on devices which go faster than sound.

[...] The resulting U-boat, labeled the Model 21, was able to make 18 knots submerged, or four knots better than it could on the surface.

The 18 knots couldn't be sustained, but the Germans were rushing development of new methods permitting even faster speeds for longer periods.

Germany was building nothing but Model 21s at the end of the war. The timetable called for 360 a year and they were to be assembled in 24 days each in huge reinforced concrete shelters between Bremen and Bremerhaven.

[Forrestal stated that "at least two or three rockets" more advanced than the V-2 were "in the development stage" "to be mass-produced in large underground factories," which seems to imply that they were not merely paper designs. He also seemed to include those rockets in the category he was discussing of potential war-winning weapons that were within six months of readiness, which again seems to indicate that they had already progressed well beyond paper designs. Was he implying that by the end of the war, Germany had in fact "monopolized an advanced weapon which will put the world in general and the United States in particular at his mercy"?

Forrestal gave a number of other examples of how much more advanced German technology was compared to American technology in many fields. Even the journalists writing these articles noticed that he carefully avoided saying anything about Germany's atomic bomb work, probably due to tight censorship on that topic.]

R. P. Linstead and T. J. Betts. 15 September 1945. ***The Intelligence Exploitation of Germany. Report of Combined Intelligence Objectives Subcommittee.*** **G-2 Division, SHAEF. Ch. 4, pp. 37, 47–51. [AFHRA A5186 electronic version pp. 904–1026]**

Certain items have been omitted because of security considerations. [...]

The exploitation of intelligence concerning German directed missiles and rocket development was one of the primary objectives of CIOS. In the initial phases of the Committee's work, considerable information was obtained from captured launching sites, propellant storage facilities and actual specimens of early V-weapons. However, it was not until the entire Peenemünde staff, together with most of their files and much of their equipment, were seized at dispersal points in southern Germany that the full story of German V-weapon research and development became available. The resultant intelligence has proven to be one of the most significant and important discoveries in the European Theater.

German authorities responsible for this work have expressed the opinion that the V-1 and V-2 were crude and elementary weapons. They have compared the present state of directed missile design with the technical status of the aircraft industry on the eve of World War I. These same authorities confidently predict that a continuation of present research in this field for another decade would change the strategical and tactical concepts of modern war.

[p. 49 of the document is missing on the microfilm roll. Can that page be located in a surviving hardcopy, or is that page still classified?]

United States and British specialists have obtained complete information covering all German directed missiles from the pioneer model "A sub-o", which employed oxygen and alcohol fuel in attaining a range of 18 miles, to the latest model of the A-9 which was capable of a 3400 mile per hour speed and a range of 2400 miles. The A-9 was an improved development of the V-2 or A-4, and was equipped with wings thereby enabling it to level off at a height of 70,000 feet. One model of this missile was equipped with a Lorin tube which provided propulsion at the peak of the trajectory, the missile was expected to result in a maximum range of 2400 miles. Other variations of this model were capable of attaining altitudes 60 miles above the earth's surface and speeds in excess of 7300 feet per second. Improved radio controls were developed to supercede the "integrating accelerometer" used in early V-weapons. Some measure of the accuracy which could be achieved with these controls is evidenced by the fact that the radio controlled models were capable of an accuracy of plus-or-minus 150 feet in contrast to a plus-or-minus 50 mile error inherent in the V-2.

German scientists engaged in directed missiles envisaged important commercial applications of the long range missile. Experiments had already been conducted on piloted models. Missiles capable of trans-Atlantic crossings in approximately 40 minutes were found on design boards and scale models were undergoing wind tunnel tests. Amazing performances were considered practical because of the lessened atmospheric resistance and gravitational pull in stratospheric regions.

The Germans particularly concentrated on controlled rockets and missiles for anti-aircraft defense. One of the most promising of the AA missiles under development was the "Wasserfall". This was a ground-to-air guided missile capable of a 2200 mile per hour speed. The "Wasserfall" was equipped with a homing device which would enable it to pick up and track a target airplane at a range of one mile. The acoustic fuse provided was designed to detonate the explosive charge within a radius of 20 meters from the target.

The “Enzian” was another type of controlled missile designed for ground-to-air or air-to-air anti-aircraft defense. This weapon was equipped with a homing device and was capable of a 900 mile per hour speed. Other German anti-aircraft missiles included the Taifun and the X-4. The Taifun was a comparatively simple and inexpensive aimed rocket capable of high speed and a 60,000 foot altitude. The X-4 was designed for air-to-air operations and wire control in order to prevent jamming or effective counter-measures.

One of the most important results of Allied investigations of German directed missile development was the vast amount of data obtained concerning aero-dynamic research in the range of supersonic speeds. This information is expected to provide invaluable assistance to research in the United States and United Kingdom.

Of particular significance were the statements, made by German experts in the rocket and controlled missile field, that much of the priority accorded their work by the German High Command was in anticipation of the use of atomic explosives. These authorities stated that KWI had repeatedly assured Hitler that an atomic explosive would be available for use within a comparatively short time. During the last months of work by the Peenemünde staff, V-weapons were designed with much smaller war-heads. Quite possibly this trend was in anticipation of the successful development of a German atomic explosive.

[See document photos on pp. 5446–5447.

This report was written by the CIOS chairs, U.S. General Thomas Jeffries Betts, Deputy G-2 of SHAEF (pp. 3287, 5028–5029), and U.K. Ministry of Supply chief advisor and F.R.S. Professor Reginald Patrick Linstead. Based on specific discoveries by their CIOS investigators, these high-ranking officials reported that:

- “The latest model of the A-9 ... was capable of a 3400 mile per hour speed and a range of 2400 miles.” That statement sounds like a description of completed hardware, not a mere drawing board design. The report also mentioned an A-9 equipped with a ramjet (Lorin) engine. From this and other reports, it sounds as if there were multiple versions of the A-9. What specific hardware and information were discovered that are not discussed in the presently unclassified reports? Can any reports that are still classified be located and released? Much more research is needed to elucidate the wartime versions and actual progress on the A-9.

- With regard to advanced versions of “the long range missile,” “experiments had already been conducted on piloted models.” Were they referring to the two-man V-4 rocket or something else? For “experiments” with “piloted models,” was the rocket launched with or without pilot(s)? If the former, did the pilot(s) survive? Did German or Austrian pilots accomplish in 1944–1945 what Alan Shepard did in 1961? If so, their names should be in the history books.

- Hitler, the German High Command, and the leading experts in the rocket programs had been “repeatedly assured ... that an atomic explosive would be available for use within a comparatively short time.” Thus the CIOS chairs contradicted the public statements of the Alsos Mission and confirmed that there was indeed a German program to develop an atomic bomb, and that it was far more than a paper design program—its hardware had passed through sufficient development, production, and testing by the end of the war that it was ready or nearly ready to be used in combat.]

THIS PAGE IS DECLASSIFIED IAW EO 13526 **AFHRA A5186 frame 0965**

United States and British specialists have obtained complete information covering all German directed missiles from the pioneer model "A sub-o", which employed oxygen and alcohol fuel in attaining a range of 18 miles, to the latest model of the A-9 which was capable of a 3400 mile per hour speed and a range of 2400 miles. The A-9 was an improved development of the V-2 or A-4, and was equipped with wings thereby enabling it to level off at a height of 70,000 feet. One model of this missile was equipped with a Lorin tube which provided propulsion at the peak of the trajectory, the missile was expected to result in a maximum range of 2400 miles. Other variations of this model were capable of attaining altitudes 60 miles above the earth's surface and speeds in excess of 7300 feet per second. Improved radio controls were developed to supercede the "integrating accelerometer" used in early V-weapons. Some measure of the accuracy which could be achieved with these controls is evidenced by the fact that the radio controlled models were capable of an accuracy of plus-or-minus 150 feet in contrast to a plus-or-minus 50 mile error inherent in the V-2.

German scientists engaged in directed missiles envisaged important commercial applications of the long range missile. Experiments had already been conducted on piloted models. Missiles capable of trans-Atlantic crossings in approximately 40 minutes were found on design boards and scale models were undergoing wind tunnel tests. Amazing performances were considered practical because of the lessened atmospheric resistance and gravitational pull in stratospheric regions.

The Germans particularly concentrated on controlled rockets and missiles for anti-aircraft defense. One of the most promising of the AA missiles under development was the "Wasserfall". This was a ground-to-air guided

W. G. A. Perring. 1946. A Critical Review of German Long-Range Rocket Development. *Journal of the American Rocket Society.* 65:1–17. Reprinted from a paper read before the Royal Aeronautical Society, London, 1 November 1945.

Serious rocket development was started in Germany in the years 1929–1930 by a few groups of private inventors. This work attracted the attention of the Army Weapons Group in 1933, and in 1937–1938 a special research and development station was set up at Peenemunde at the cost of 300 million marks, and the work was transferred from Berlin to this new station at about that time.

Peenemunde concentrated mainly on bi-fuel rockets, employing liquid oxygen as the source of oxygen for the combustion of the fuel. Work was started on a range of rockets which they designated Al to A10, only one of which, namely, A4 or as we know it V2, ever being used operationally. [...]

Apart from these main rocket developments, there were many other developments going on all over Germany; in some of these solid fuels were used, and in others nitric acid was the oxygen carrier, and Diesel oil or alcohol the other fuel. [...]

The highest velocity reached is at all burnt, the rocket is then traveling at 5000 ft. per sec. and it is interesting to note that at this velocity the rocket motor is developing well over 600,000 horsepower. The stagnation temperature corresponding to a velocity of 5000 ft. per sec. is about 1400^oK, and in view of this it might be expected that the skin temperatures of the rocket during flight would tend to be high and approach the stagnation value.

To check this point a careful examination of the rocket skin was undertaken, and both from an examination of the condition of the paint, and a metallurgical examination of the skin material, it was concluded that the skin temperatures had not exceeded about 900^oK. This figure agrees very closely with measurements that the Germans were able to make on an actual rocket in flight. In their tests the Germans inserted small discs of various metals of known melting point into the skin of the rocket and connected these into electrical circuits. As each disc melted, a signal was transmitted by telemetering to a ground station. It was found that the skin temperatures nowhere exceed 920^oK, conduction and radiation losses therefore must have kept the skin temperature down well below the stagnation temperature. [...]

A10 was a still more ambitious rocket, in the project stage only; it was to weigh about 85 tons, and was intended to carry the A9 rocket into the stratosphere, and then be jettisoned, A9 and A10, therefore, were separate stages of a two-stage rocket.

Table II gives the specific impulse of a number of fuels, calculated on the basis of working conditions corresponding to the venturi characteristics of the A4 rocket.

Most practical values of the S_I [specific impulse] lies between 180–240, but it will be seen from the table that by using hydrogen and oxygen the value could be pushed up to well over 300 while still retaining a moderate combustion temperature, and some still further improvement in this S_I would be possible at the expense of the working temperatures and pressures.

[...] Starting with the A4 rocket, we have assumed that the warhead is removed, and replaced by a pressure cabin and pilot, and in addition, the rocket is fitted with wings; the wing area being arranged to provide for a landing wing loading of 35 lb. per sq. ft.

Three cases will be touched on briefly. In the first, the A4 rocket with wings is assumed to be fired vertically, and controlled in the same manner as a normal A4 rocket until it reaches the top of its trajectory, when the pilot takes over and glides the rocket to the ground along its optimum glide path.

In the other two cases, the A4 rocket with wings, has been assumed to be taken up by means of a booster rocket rather on the lines of the German A10 project mentioned earlier in the lecture. In this way the rocket reaches a height of 80,000 feet before being released at a speed of 3000 m.p.h. (these conditions corresponding to the height and speed reached by the A4 rocket with wings at all burnt, when it is fired vertically upwards in the normal way). From this point onwards the rocket with its full fuel continues the flight, and in the first of these boosted cases it has been assumed that the rocket venturi is redesigned, and now provides a thrust corresponding to level flight at 1640 m.p.h., at 80,000 feet, while in the other the redesigned venturi provides a thrust which enables the rocket to continue the climb. The results of these calculations are compared with the trajectory of the normal A4 rocket without wings.

The first striking thing about the results is the effect that the addition of wings has on range. The range of 180 miles of the normal A4 rocket without wings has now been raised to 350 miles.

Still more striking however is the effect of the booster on the general performance. Ranges of 1500 to 3000 miles now appear to be possible, and the advantage of continuing the climb at the end of the booster stage is also very marked. It is interesting to note that with a rocket boosted in this way it would be possible to complete the journey from London to New York in well under the hour.

The first of the two cases of the rocket with wings presents no problem that is outside of the experience already gained by the Germans during their work on the A4 rocket, the third case however does raise many new problems. It contemplates for example flight at over 8000 m.p.h., this means a stagnation temperature of nearly 7000^oK, so that even though radiation may play an important part in keeping, the temperature down, the pilot would nevertheless find himself enclosed in a body the skin of which, to say the least of it, was uncomfortably hot. Over a large part of the flight too, the rocket would be moving on a free trajectory, since the wings cannot provide sufficient lifting force to control the motion. Over this part of the trajectory the pilot would be subject to zero g, and it would not be until the rocket returned, to a point about 28 miles above the earth's surface that the pilot could begin to assume control of his machine.

The booster contemplated in connection with these schemes would of course be very large; it would certainly weigh about 100 tons, and the Germans in planning their schemes had hoped that the booster after being jettisoned, would be recoverable. [...]

I should like in conclusion to say how much I am indebted to the many workers in this field who took part in the A4 rocket investigations, on whose work I have drawn quite freely in preparing the present lecture.

[W. G. A. Perring, Deputy Director of Research and Development at the Royal Aircraft Establishment (RAE) in Farnborough, studied intelligence reports and recovered pieces from wartime German rocket tests in order to accurately inform the British government of the design and capabilities of V-2 rockets before they were launched against Allied targets.

Perring's report here is "drawn quite freely" from detailed postwar investigations of later, more advanced German rocket research and development, and it reports presumed German work on:

- "Rocket developments... going on all over Germany," not just at Peenemünde.
- Development of solid propellant rockets.
- Development of storable and hypergolic liquid rocket propellants, such as inhibited fuming nitric acid oxidizer and Diesel fuel.
- Work on liquid hydrogen and liquid oxygen rocket propellants to obtain specific impulse values "well over 300 while still retaining a moderate combustion temperature." Compared to the alcohol and liquid oxygen propellant in the standard A-4, that would increase a rocket's exhaust velocity by well over 50% and double or triple the rocket's range.
- Both well-known trajectories in which rockets follow a parabolic arc before reentering the atmosphere, and also less well-known trajectories in which the rockets level off at some fixed altitude and continue powered flight horizontally toward their target, as described by the German prisoner of war on p. 5334.
- A reusable A-10 booster stage, which suggests that it was never planned or necessary to build many of them.
- Construction of a modified A-4 (A-9) rocket having a pressure cabin and pilot.
- Experimental measurements of and work to deal with heat transfer to rockets during reentry into the earth's atmosphere.]

MR. W. G. A. PERRING, WITH HIS REMARKABLY ACCURATE RECONSTRUCTION OF A V-2 ROCKET, BASED ON FRAGMENTS FOUND IN SWEDEN BEFORE THE ATTACKS BEGAN.

Mr. W. G. A. Perring was concerned with research work on the German V-2 rocket, and was able to make a remarkably accurate reconstruction of this weapon and assess its potentialities from some two tons of fragments found after one of these weapons had exploded over Sweden before the attacks on Britain were made. He is seen holding his diagrammatic model.

7.12.46
B/1

Le Dr. Heinrich KLEIN, domicilié à DUSSELDORF, est l'un des 14 savants allemands détenteurs de la "Lilienthalgedenkmünze". Il était chef-constructeur chez Rheinmetall Borsig et le successeur désigné du Prof. WANINGER.

Le Dr. KLEIN n'a pris encore aucun engagement avec les Anglais.

Il est chargé de règler les affaires courantes de la firme Rheinmetall Borsig. Il a déclaré que la Direction de Rheinmetall au complet se trouve à UNTERLUESS. Mais aucune décision n'a été prise jusqu'alors en vue de leur affectation.

Il s'agit de :

Obering. Walter DIECK,	DILLENBURG
Ing. STUCHLEN	UNTERLUESS
Obering. KLEINSCHMIDT	"
Dr. KOBLONEH	"
Ing. PRIER	"
Obering. KORDES	"

Son champ d'action comporte principalement la construction de fusées volantes... pouvant franchir l'Atlantique en 40 minutes.

En outre, nouveau procédé de carburant synthétique, etc.

Ses travaux, figurent au rapport de la "CIOS" (dont extrait ci-après) commission mixte anglo-américaine chargée d'explorer l'Allemagne dans le domaine technique et scientifique. Cette Commission a suivi les troupes alliées à leur entrée en Allemagne.

Figure E.134: 21 February 1947 French background investigation on Heinrich Klein: "His field of experience mainly involves the construction of flying rockets... capable of crossing the Atlantic in 40 minutes." [Archives of the French Army Ministry of Defense, courtesy of Norberto Lahuerta].

WAAF Tells of Aid in Saving New York. *New York Times*, 6 October 1945, p. 18.

British Woman, Now Assigned to U.S., Shows How Her Unit Upset V-Bombing Plans

Standing high over the skyline of New York, the city her military intelligence is credited with helping to save from German rocket-bombing, Flight Officer Constance Babington-Smith of the British Women's Auxiliary Air Force explained yesterday how she did it, at a press conference sponsored by the British Information Services on the sixty-fifth floor of 30 Rockefeller Plaza.

For all her mastery of the intelligence officer's technique in interpreting air reconnaissance photographs for secret information pertaining to enemy aircraft operations, it became apparent during the interview that Flight Officer Babington-Smith's sky-blue eyes, ready imagination and leaping logic were the real clues to her success in the war work that she "really loved." [...]

Miss Smith used only a stereoscope and a measuring magnifier, but she maintained that "one's eyes are the most important—not instruments." Her mission was to detect, from aerial reconnaissance photographs, new developments of German aircraft and aircraft factories, and thus to provide the Allied raiders with vital bombing targets and other intelligence.

In May, 1943, Miss Smith became the first Allied person to detect the enemy's new "vengeance weapon," the V-1, or robot plane, as it was being developed by Germany at an experimental center in Peenemünde, on the Baltic. In a reconnaissance photograph of this place, she interpreted a small, curving black shadow as a ramp; and a tiny, T-shaped, white blot above it as an airplane, the V-1.

On the basis of her discovery Allied air raiders bombed Peenemünde, killing 800 German scientific experts and thereby, by Germany's own admission, retarded the enemy's aeronautical development work by six months so that Germany's elaborate plans for rocket-bombing the United States could not be completed in time.

[In this remarkable article, the U.K.'s most celebrated wartime aerial reconnaissance photo interpreter, the British Information Services, and the *New York Times* all stated clearly and unequivocally that Germany was within only months of attacking New York with rockets when the war ended, and that the New York rockets would have been ready six months sooner if not for Allied bombing of relevant sites in Europe. This information also strongly suggests that the German atomic bomb was ready or almost ready at the end of the war, since a conventional explosive warhead would not do much damage or justify all the costs and resources required to develop a rocket that could reach New York.

If the German atomic bomb and the New York rocket were within months of completion at the end of the war, they could not have been merely at the stage of paper designs when the war ended. German, British, and U.S. experts were all keenly aware that it required years of intensive work both for atomic bombs and for long-range rockets to progress from paper designs to deployable final products.

For more information on Constance Babington-Smith, see:

https://www.theguardian.com/news/2000/aug/12/guardianobituaries]

U.S. Army Air Forces General Henry H. Arnold. 9 January 1945 address to Scientific Advisory Group. Quoted in Thomas A. Sturm. 1967. *The USAF Scientific Advisory Board: Its First Twenty Years 1944–1964.* Washington, D.C.: U.S. Government Printing Office. p. 2

I don't think we dare muddle through the next twenty years the way we have... the last twenty years. I have worked with von Kármán the last twenty years, and I was sometimes scared by the knowledge he had that we weren't using. ... I don't want ever again to have the United States caught the way we were this time.

Arnold Urges Single Defense Department. *Washington Post.* 20 October 1945 pp. 1–2.

AAF Head Asks Co-Equal Status for Air Arm as Best Peace Insurance.

Gen. Henry H. Arnold yesterday warned Congress the next war will come through the air and asked co-equal status for air power in a unified defense system as "the best insurance of peace."

The graying Chief of Army Air Forces backed the War Department's call for one strong department of national defense with statistics charting the "terrifying possibilities" of new air weapons. [...]

Flanked by a group of veteran Air Corps officers, the Army Air Forces commander told how the German V-2 bombs alone, perfected with wings, radar and electronic devices, can now travel over 3000 miles and at 2000 miles hit a target "on the button." [...]

He said there can no longer be defense against the missiles themselves—blows at the source of them must be the goal. [...]

Discussing the atom bomb, the German V-2, jet, bomber and cargo plane developments, Arnold stressed the "extraordinary versatility" of the new air weapons and glimpsed future "more radical" uses. [...]

Arnold said one German jet plane was capable of knocking down 17 American Flying Fortresses. Had Germany concentrated on its jet fighters, he said it would have been "far more difficult to get into Germany."

[How did General Arnold know that German rockets "can now travel" 2000–3000 miles and "hit a target on the button"? That public statement suggests that Germany successfully conducted such a test before the end of the war, and that Arnold had obtained evidence detailing that test. For another document that appears to describe such a test, see Alfred Gründler's testimony on p. 5347.]

Arnold Advocates Co-Equal Air Force. *New York Times* 20 October 1945 p. 3.

He Calls This Vital to U.S. as Only Fliers Could Hit Quickly at Atomic Bomb Source

Creation of a single national defense organization, in which the air arm will have coequal strength and influence with the Army and Navy, is essential if this country is to be prepared against future aggression, Gen. Henry H. Arnold, commander of the Army Air Forces, told the Senate Military Affairs Committee today. [...]

Pleading for unification, which would give the nation's air arm the same position it won with difficulty during the war, General Arnold said:

"It is apparent from any school room globe that war can come through the air to the very heart of this country. It can come with weapons of types now in our possession, and without any land or naval action.

Speed Declared Essential

"Such developments as the atomic bomb, the V-2 and the whole range of radio-directed and homing missiles accentuate the security problems of the air. Responsibility for a rapid and powerful offensive against the source will rest on the air force."

3,000-Mile V-2 Near, Says Arnold. *New York Times* 20 October 1945 p. 3.

General Arnold said that a future war might start with air attacks launched from bases 3,000 miles away, pointing out that the United States even now could blanket most of Asia and Europe and a large part of Africa from bases within this country.

The German V-2 rocket now has a range of 250 miles, he said, but by attaching wings and electronic guiding devices it can easily travel 3,000 miles or more. Such a development, he said, "is just in the offing."

He also said that if Germany had concentrated on the jet-propelled fighter it used toward the end of the war, the Allies would have had a much harder time destroying the Luftwaffe.

"According to our information," he said, "one German pilot in one German jet plane could knock down seventeen to twenty of our Flying Fortresses."

Henry H. Arnold. 12 November 1945. *Third Report of the Commanding General of the Army Air Forces to the Secretary of War.* Baltimore, Maryland: Schneidereith & Sons.

[pp. 8, 10:] The ME-262 jet plane, Germany's greatest hope, and, we must state frankly, the greatest threat to continued bomber operations, was then in production. Under no circumstances, Hitler declared, would the ME-262 be used as anything but a bomber. [...]

Hitler persisted in this amazing decision from April until October, a period which saw the Invasion and the sweep across France. As a bomber, the ME-262 did nothing. The ME-262s which our airmen fought during that period were a few Galland had secured, despite Hitler's edict, for an "Experimental Unit." In October, when Hitler relented, only a handful were released to the fighter arm, and it was 1945 before the bomber idea was finally discarded.

[p. 30:] Very important work remains to be done. [...] One is the making of a large-scale photographic map of the conquered country, something sorely needed and partially obtained only with great difficulty during the war—a bird's eye view of Germany, just in case. Another is the job of disarming the Luftwaffe—not only pullings its fangs but plucking its brains.

Air disarmament includes seeking out and impounding Luftwaffe documents, locating its technicians, scientists and experimental specialists for interrogation, and securing the records of their work and experiments. There is materiel of vital interest for testing and development at Wright Field. Strange devices are being ferreted out, crated, and shipped for study—from blind landing equipment to infra-red meteorological instruments and range finders, from radar apparatus to crew chief stands, from jet engines to bomb sights, flak guns to airborne cannon, compasses and cameras to medical documents and automatic pilots.

Whatever the Germans had of worth, we shall have. Whatever they hoped to develop, we shall know about. We want to make sure it is not being worked on under the guise of a peacetime product. Winning this war was a hard job. Air power intends to do its share toward keeping the peace.

[pp. 66–68:] At lower right is the X-4, a wire controlled, rocket-propelled gyro-stabilized missile, to be launched from parent plane against bombers. X-4 was almost ready for use. [...] Potency of X-4 (right) was tremendously increased by proximity fuse.

[...] We must look at the future of aerial warfare in the light of the following considerations:

1. Aircraft, piloted or pilotless, will move at speeds far beyond the velocity of sound, well over 700 miles per hour.

2. Improvements in aerodynamics, propulsion, and electronic control will enable unmanned devices to transport means of destruction to targets at distances up to many thousands of miles. However, until such time as guided missiles are so developed that there is no further need for manned aircraft, research in the field of "conventional" aircraft of improved design must be vigorously pursued.

3. Small amounts of explosive materials, as in atomic bombs, will cause destruction of many square

miles.

4. Defense against present day aircraft may be perfected by target-seeking missiles.

5. Only aircraft or missiles moving at extreme speeds will be able to penetrate enemy territory protected by such defenses.

6. A communications system between control center and each individual aircraft will be established.

7. Location and observation of targets, take-off, navigation and landing of aircraft, and communications will be independent of visibility or weather.

8. Fully equipped airborne task forces will be able to strike at far distant points and will be totally supplied by air.

[...] Further, the great unit cost of the atomic bomb means that as nearly as possible every one must be delivered to its intended target. This can be done in one of several ways, all of which involve air power. For example, the following evolution may be suggested:

a. Today, our Army Air Forces are the recognized masters of strategic bombing. Until others can match the present efficiency of our own antiaircraft defenses, we can run a large air operation for the sole purpose of delivering one or two atomic bombs. Our experience in the war suggests that the percentage of failures in an operation of this kind would be low.

b. When improved antiaircraft defenses make this impracticable, we should be ready with a weapon of the general type of the German V-2 rocket, having greatly improved range and precision, and launched from great distances. V-2 is ideally suited to deliver atomic explosives, because effective defense against it would prove extremely difficult.

c. If defenses which can cope even with such a 3,000-mile-per-hour projectile are developed, we must be ready to launch such projectiles nearer the target, to give them a shorter time of flight and make them harder to detect and destroy. We must be ready to launch them from unexpected directions. This can be done from true space ships, capable of operating outside the earth's atmosphere. The design of such a ship is all but practicable today; research will unquestionably bring it into being within the foreseeable future.

[...] Complete dispersal of our cities and moving vital industries underground on a sufficiently large scale would be overwhelmingly expensive. [...]

Although there now appear to be insurmountable difficulties in an active defense against future atomic projectiles similar to the German V-2 but armed with atomic explosives, this condition should only intensify our efforts to discover an effective means of defense. [...]

Jet propulsion is in its infancy despite the fact that this war has evolved six distinct methods of utilizing atmospheric oxygen for propulsion, such as (1) *motorjet*—or reciprocating engine plus ducted fan, (2) *turboprop*—a gas turbine plus propeller, (3) *turbofan*—a gas turbine plus ducted fan, (4) *turbojet*—a gas turbine plus jet, (5) *ramjet*—a continuous jet with compression by aerodynamic ram, and (6) *pulsojet*—or intermittent jet. These new and strange sounding words will be familiar ones in our speech in the near future, and right now they carry more meaning for Americans than any other six words I know.

[Arnold's statements in the above report, especially those regarding the use of long-range rockets or spacecraft to deliver atomic bombs, were widely reported in newspapers. As just one example, see:

Space Ships Flying A-Bomb Rockets Visioned by Arnold. *Los Angeles Times* 12 November 1945 p. 1.

For an example of the press reporting this idea in detail, see p. 5460.]

Traitor Suspect Holds Secret Key of Nazis' V-Ten. *Toronto Daily Star* 12 November 1945 p. 28.

Stockholm, Nov 12—(AP)—The newspaper Aftonbladet today quoted an unnamed British lieutenant as saying that the Swedish engineer, Nils Werner Larsson, on trial for delivering military secrets to both Germany and the Allies, held the key to construction of the whole series of Nazi vengeance weapons from V-1 to V-10.

The V-10 was the weapon which the Germans expected to hurl across the Atlantic in 35 minutes to bombard North America. It was in blueprint stage when Germany surrendered.

The newspaper said plans for the V-10 reached the United States seven weeks ago and formed the basis for Gen. Henry H. Arnold's reference to "space ships" in his report yesterday to the U.S. secretary of war.

In the report, Gen. Arnold envisaged space ships travelling 3,000 miles an hour "operating outside the earth's atmosphere."

Larsson is charged specifically with offering German military secrets to Allied military representatives in Sweden and of delivering an improved Swedish machine pistol to the Germans, presumably to create confidence in him.

The newspaper quoted the lieutenant, who recently visited Sweden from Hamburg, as saying that Larsson had great technical knowledge and had worked in the German experimental laboratories in Peenemuende in 1943, where V weapons were developed.

Larsson left Sweden in 1943 for Germany and assisted German discoverers and builders of the V weapons, the newspaper said. After the German collapse, Larsson was said to have had freedom of movement in Germany. The British officer was reported to have met Larsson in an officers' barracks in Hamburg a few weeks ago.

Larsson was arrested by the Swedes at the border, apparently while en route home from Germany.

Swede Arrested as Double Agent. *New York Times* 13 November 1945 p. 5

Accused of Selling Arms Data to Germans and Allies—Tells of V-10 Space Ship

STOCKHOLM, Sweden, Nov. 12—A Swedish engineer, Nils Werner Larsson, who is said to possess the secrets of all Germany's V-weapons, is in jail here accused of having sold designs for secret Swedish weapons to both the Germans and the Allies during the war and of desertion from the Swedish Army.

The Aftonbladet quoted a British officer who said that Larsson had the key to all German V-weapons from V-1 to V-10, which was intended for wiping out American cities. Its designs are now in Washington and are probably what Gen. H. H. Arnold referred to in yesterday's sensational report on space ships.

Larsson made contact with the British Secret Service in the summer of 1943 and agreed to work for the Allies in Germany. He gained the Germans' confidence by selling their agents designs for a new Swedish submachine gun and an anti-tank gun after first having given them to the Allies. The Germans trusted him and in October he went to Germany. The Germans, realizing his great gifts as a constructor, immediately sent him to Peenemuende to work on V-bombs.

He worked for the Allies too and was permitted to move freely in Germany after her collapse. A British officer met him in Hamburg, where Larsson told about his work in Peenemuende. Larsson seemed to be extremely persona grata with the British authorities in Germany and was permitted to go to Norway, whence he returned here.

Larsson said today that all other variations of V-weapons were vastly surpassed by the V-10, which, according to German plans, was to cross the Atlantic in thirty-five minutes and devastate American industries and cities. Later it was to be developed into an "absolute stratosphere ship" with which it should be possible to cruise around in space under human control.

[Versions of this story were also published in other newspapers; see for example:

Swedes Reveal V-10 Weapon as Nazi "Space Ship." *Chicago Tribune* 13 November 1945 p. 2 [http://archives.chicagotribune.com/1945/11/13/page/2/article/swedes-reveal-v-10-weapon-as-nazi-space-ship]

U.S. Has V-10 Plans, Says Swedish Paper. *Los Angeles Times* 13 November 1945 p. 7.

"V-10" seems to have meant the A-9/A-10, which would have been capable of everything described here: carrying pilots, traveling through space from Germany to the United States, and "devastating American cities" (especially if Germany had an atomic bomb the rocket could carry, as discussed in Appendix D). The A-10 was part of Wernher von Braun's series of Aggregat rockets from A-1 through A-10. Since the V-1 (unrelated cruise missile) and V-2 (renamed A-4 rocket) were such well-known names, someone involved in reporting this German work probably tried to apply V-labels to all of the Aggregat rocket numbers. In 1949, General Henry Arnold confirmed that the V-10 was indeed the A-10, and that physical rockets were being built, not just designed (p. 5466).

Nils Werner Larsson led a very exciting life. For more information on him as well as some of the other German rocket information he provided, see p. 5670.]

The 36-Hour War: Arnold Report Hints at the Catastrophe of the Next Great Conflict. *Life*. 15 November 1945. 19:21:27. [See document photos on pp. 5461–5464.] [https://books.google.com/books?id=6UsEAAAAMBAJ&pg=PA27&dq=Life+36+Hour+War&hl=en&sa=X&ved=0ahUKEwjVgMfcr9fiAhVFh-AKHe36D0QQ6AEIKDAA#v=onepage&q=Life%2036%20Hour%20War&f=false https://blog.nuclearsecrecy.com/2013/04/05/the-36-hour-war-life-magazine-1945/]

The start of another war, said General Arnold, might come with shattering speed: "With present equipment an enemy air power can, without warning, pass over all formerly visualized barriers and can deliver devastating blows at our population centers and our industrial, economic or governmental heart even before surface forces can be deployed."

[Not even U.S. bombers could "pass over all formerly visualized barriers" at that time, since fighters, anti-aircraft guns, and anti-aircraft rockets were still potential barriers for them. Was General Arnold admitting that German intercontinental rockets, which could indeed pass over all barriers, were "present equipment" and had been fully developed by the end of the war?

Based directly on information from General Arnold, this *Life* article presented illustrations of a number of very German-like rockets arcing over the Atlantic and delivering nuclear bombs to major U.S. cities, including a full-page illustration of a nuclear explosion in Washington, D.C., and another full-page illustration of the rubble of New York City after a nuclear explosion. Some of the illustrations are shown on the following pages. Was this General Arnold's idea of "present equipment" based on what his investigators found in Germany and Austria at the end of the war? What exactly did they find?

A two-page illustration in the article also depicted a massive underground military complex with areas for manufacturing and storing nuclear weapons and rockets, launching nuclear-armed rockets, providing living quarters for all the workers in the underground complex, and supplying power for the complex. The article portrays such a complex as something that the United States might build, but in 1945, the United States did not have such underground complexes, plans to build them, or intercontinental rockets with which to equip them. However, Germany had spent several years during the war developing just such underground complexes. How far did Germany actually get in making these sorts of underground nuclear weapons production/intercontinental rocket production/launching complexes operational? What did General Arnold know from his investigators?

One of the main engineers in charge of designing and build German underground complexes during the war, Karl Fiebinger, worked in the United States for many years after the war as a "consultant" on secretive government projects (pp. 4986–4991, 4993). His accomplishments in the United States included designing underground missile silos for intercontinental ballistic missiles, which may shed light on the nature and extent of his wartime work for Germany [Freund and Perz 1987, p. 44]. Another person who apparently did similar work for both wartime Germany and the postwar United States was Hans Brand (German, 1879–1959). Thus this arm of the long-standing postwar "nuclear triad," nuclear-armed intercontinental ballistic missiles based in underground silos, appears to have been directly derived from German-speaking creators and their creations.

THE 36-HOUR WAR BEGINS WITH THE ATOMIC BOMBARDMENT OF KEY U.S. CITIES. HERE A SHOWER OF WHITE-HOT ENEMY ROCKETS FALLS ON WASHINGTON, D.C.

THE 36-HOUR WAR

ARNOLD REPORT HINTS AT THE CATASTROPHE OF THE NEXT GREAT CONFLICT

This week General Henry H. Arnold, commanding officer of the Army Air Forces, published his third formal report to the Secretary of War. The report was not only a history of Air Forces activities at the end of the late war but a warning of future wars. Said the general: "In the past, the United States has shown a dangerous willingness to be caught in a position of having to start a war with equipment and doctrines used at the end of a preceding war. . . . Military Air Power should . . . be measured to a large extent by the ability of the existing Air Force to absorb in time of emergency . . . new ideas and techniques."

The Army Air Forces, said General Arnold, were fully prepared to absorb new ideas: "We can run a large air operation for the sole purpose of delivering one or two atomic bombs. . . . When improved antiaircraft defenses make this impracticable, we should be ready with a weapon of the general type of the German V-2 rocket, having greatly improved range and precision. . . ."

Such weapons as these, in the hands of other nations as well as the U.S., would make possible the ghastliest of all wars. Hostilities would begin with the explosion of atomic bombs in cities like London, Paris, Moscow or Washington (*above*). The destruction caused by the bombs would be so swift and terrible that the war might well be decided in 36 hours. The illustrations on these pages show how such a war might be fought if it came.

But General Arnold did not suggest that improved weapons were the only safeguard of the U.S. It would be better, he said, to use bombs for peace now rather than for war later, possibly by using them as a power to enforce decisions of the United Nations Organization's Security Council.

THE ATOM BOMBS DESCEND ON U.S.

The start of another war, said General Arnold, might come with shattering speed: "With present equipment an enemy air power can, without warning, pass over all formerly visualized barriers and can deliver devastating blows at our population centers and our industrial, economic or governmental heart even before surface forces can be deployed."

In the panorama above, looking eastward from 3,000 miles above the Pacific, LIFE's artist has shown the U.S. as it might appear a very few years from now, with a great shower of enemy rockets falling on 13 key U.S. centers. Within a few seconds atomic bombs have exploded over New York, Chicago, San Francisco, Los Angeles, Philadelphia, Boulder Dam, New Orleans, Denver, Washington, Salt Lake City, Seattle, Kansas City and Knoxville. One bomb (*second from left*) has been exploded high above the earth by a U.S. defensive rocket (*see illustration on page 31*). In the cities more than 10,000,000 people have been instantly killed by the bombs. The enemy's purpose is not to destroy industry, which is an objective only in long old-fashioned wars like the last one, but to paralyze the U.S. by destroying its people.

The rockets above, white-hot from traveling part of their journey through the atmosphere at three miles a second, have in a little more than an hour soared 1,800 miles up and some 8,000 miles around the earth from equatorial Africa. There an enemy of the U.S. has built its rocket-launching sites quickly and secretly in the jungle to escape detection by the UNO Security Council. In their flight the rockets coast most of the way through empty space, where the stars are out at noon. The thin luminous band on the horizon is the earth's atmosphere.

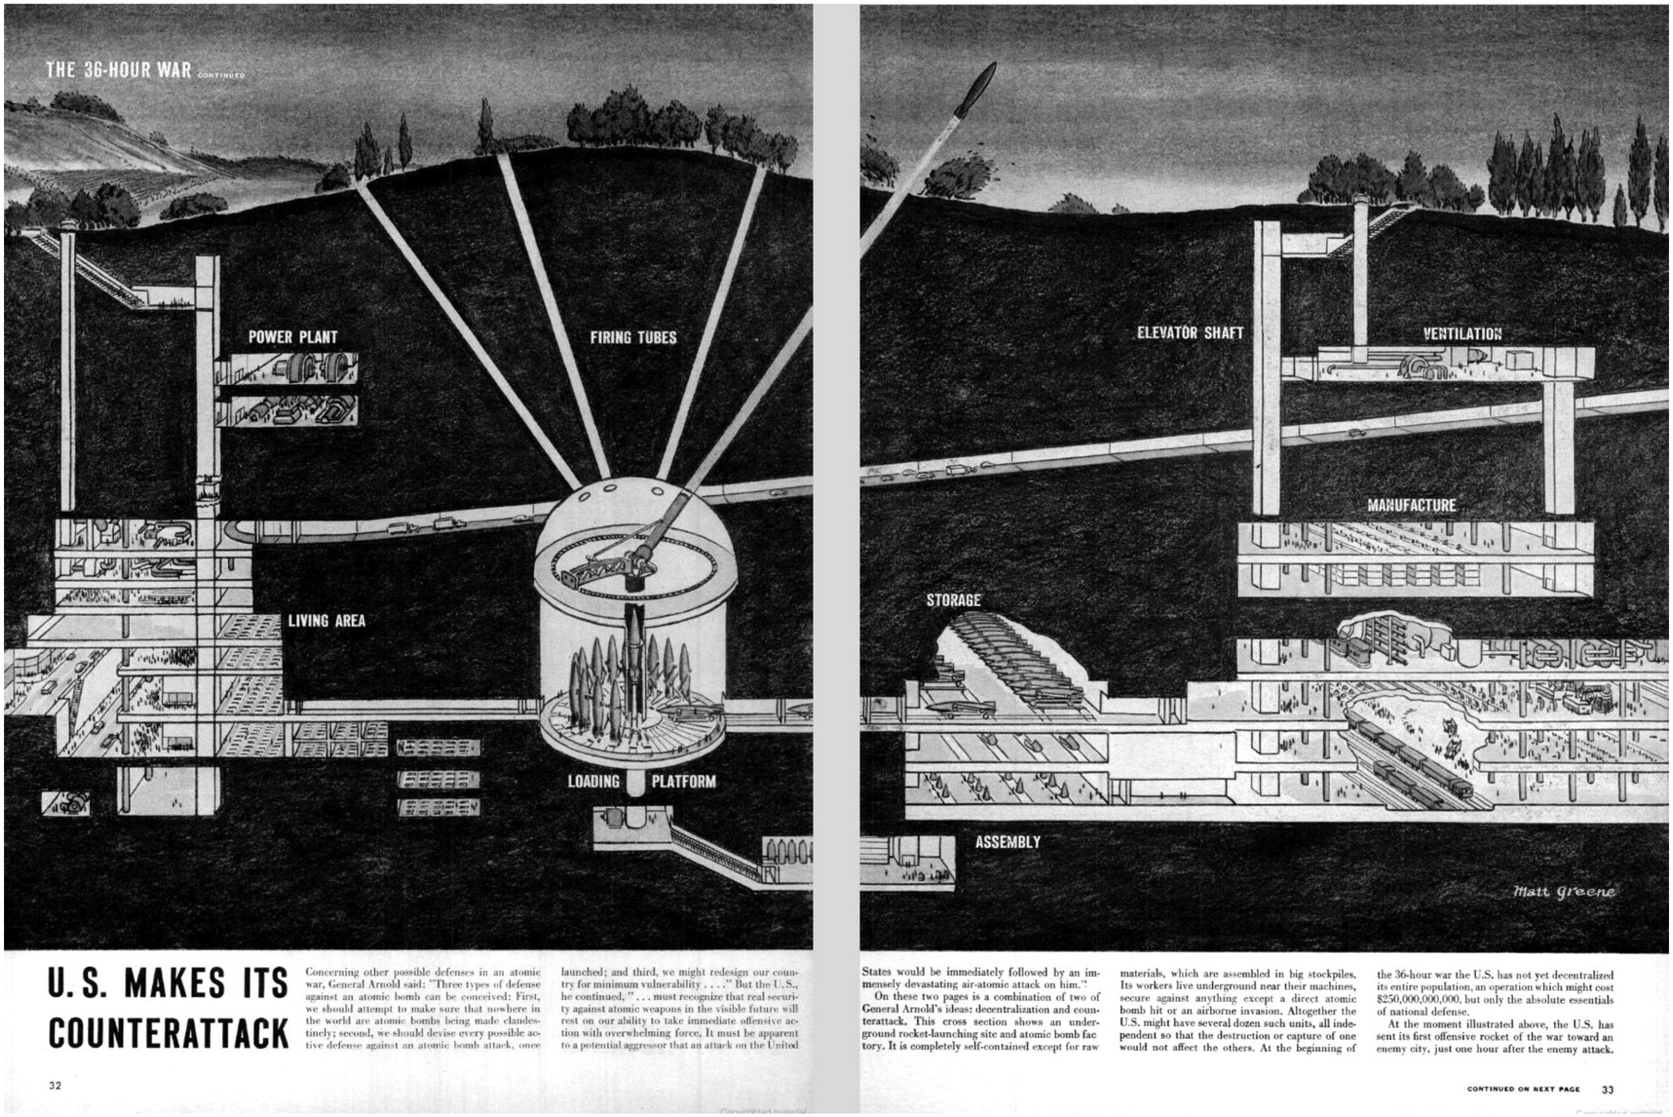
Figure E.136: Illustration from The 36-Hour War.



U. S. MAKES ITS COUNTERATTACK

Concerning other possible defenses in an atomic war, General Arnold said: "Three types of defense against an atomic bomb can be conceived: First, we should attempt to make sure that nowhere in the world are atomic bombs being made clandestinely; second, we should devise every possible active defense against an atomic bomb attack, once launched; and third, we might redesign our country for minimum vulnerability . . . ." But the U.S., he continued, " . . . must recognize that real security against atomic weapons in the visible future will rest on our ability to take immediate offensive action with overwhelming force. It must be apparent to a potential aggressor that an attack on the United States would be immediately followed by an immensely devastating air-atomic attack on him."

On these two pages is a combination of two of General Arnold's ideas: decentralization and counterattack. This cross section shows an underground rocket-launching site and atomic bomb fac tory. It is completely self-contained except for raw materials, which are assembled in big stockpiles. Its workers live underground near their machines, secure against anything except a direct atomic bomb hit or an airborne invasion. Altogether the U.S. might have several dozen such units, all independent so that the destruction or capture of one would not affect the others. At the beginning of the 36-hour war the U.S. has not yet decentralized its entire population, an operation which might cost $250,000,000,000, but only the absolute essentials of national defense.

At the moment illustrated above, the U.S. has sent its first offensive rocket of the war toward an enemy city, just one hour after the enemy attack.

Figure E.138: Illustration from The 36-Hour War.

Carl A. Spaatz. Air Power in the Atomic Age. *Collier's* 8 December 1945 pp. 11–12, 83–84.

[...] At the top of its arc the V-2 traveled at an altitude of 60 or 70 miles and reached a maximum speed of about 3,500 miles an hour—approximately a mile a second. It was a bifuel rocket utilizing liquid oxygen and a hydrocarbon like alcohol or hydrogen peroxide.

Three improvements would make a similar rocket almost a perfect weapon: more range, increased explosive power, greater accuracy. The Germans were readying a transatlantic model when the war ended. Our atomic development supplies the explosive. There is no visible barrier to solution of the accuracy problem. [...]

[General Spaatz was the commander of the U.S. Strategic Air Forces in Europe during World War II and would have had a detailed knowledge of all relevant intelligence, both during and after the war. Seven months after the end of the war in Europe, Spaatz wrote that he knew the Germans had been **readying** a transatlantic rocket (presumably the A-9/A-10). Thus such rockets were far more than a blueprint design–they were actually being prepared for use against the United States. How exactly did Spaatz know that? Henry Arnold made a very similar statement in 1949 (p. 5466). Where are the U.S. reports on this topic located now? Where are any captured German documents and hardware?]

Balanced Forces Urged by Arnold. *New York Times* 9 December 1945 p. 31.

General, at Pennsylvania Dinner, Calls for Close Watch on Potential Enemies

General of the Army Henry H. Arnold, commanding general of the Army Air Forces, advocating a policy of "offensive readiness," said last night that this country needed an intelligence service that would keep us informed of the intentions and scientific developments of possible enemies. He also called for the maintenance of "balanced armed forces" to insure peace. [...]

Forecasting the further development and perfection of super-bombers—for which no military target will seem too distant—General Arnold pictured radar-directed V-2 weapons equipped with atomic bombs, and said the damage would be "a far too terrible thing to contemplate." While there are no certain means to stop such weapons, once launched, he added, our aids and destructive equipment can make their use more difficult.

Scientific Research Stressed

"One necessity to meet the future is an intelligence service that will always keep us informed of the possible intentions and the scientific developments of possible enemies," he continued. "We must use our most brilliant scientists to develop better weapons more quickly and more effectively. We must take advantage of the bases we now have to be closer to an enemy's vital points with our weapons than he is to ours. We must use the most modern weapons of all kinds so that we can beat any potential opponent to the draw. Our hope lies, then, in a policy of offensive readiness to perpetuate peace—to provide for national security."

The general pointed out that this does not mean we should ever become an aggressor nation. He emphasized it was a plan of insuring peace, since "there will be little or no time for recovery after the first blow is struck by the attacking nation" in any future war. [...]

Henry H. Arnold. 1946. Air Force in the Atomic Age: Future of the Ballistic Rocket [Masters and Way 2007].

[...] The Twentieth Air Force, using atomic bombs, could in one day's raid destroy more of Japan's industry than was actually done in the entire B-29 campaign. [...] A similar fate would have enveloped England had the Germans obtained atomic explosives for their V weapons.

We have now flown a B-29 nonstop for a distance of over 8,000 miles. Ranges of 10,000 miles for one-way trips with newer types of aircraft appear to be a possibility of the near future. [...]

Looking only a little farther to the future, we must consider developments of the V-2 rocket. By designing a rocket consisting mostly of fuel, a speed of 3,400 miles per hour and a range of 200 miles was obtained in operations against England. This rocket weighed 14 tons and delivered only 1 ton of explosive. The Germans had under design a longer range rocket, using a pick-a-back principle. A large rocket was to carry a smaller one up to a speed of 2,500 miles per hour. At this point the smaller one was to take off on its own, attaining a speed of 5,800 miles per hour, which would carry it 500 miles. The combined rocket would weigh 100 tons and deliver 1 ton of explosive. Designs incorporating winged rocket predicted an increase of range to 300 miles for V-2 by finishing the trajectory in a glide and an increase to 3,000 miles for rockets of the 100-ton class. This phenomenal increase in range was based on a trajectory in which the rocket would bounce out of the lower atmosphere into the stratosphere in a succession of jumps (like a stone skipping on water) and end up in a glide. Extensions of these techniques to rockets of more than two stages permit increasing the range indefinitely with a progressive decrease in percent of payload. However, the achievement of range alone is of little strategic value unless it leads to effective and economical destruction of specific targets. [...]

Very long-range rockets were not a serious threat before the atomic bomb because of the high ratio of the weight—and consequently the cost—of the vehicle compared to the explosive load. Even a two-stage rocket would barely break even economically—the cost of destroying a square mile by this means being comparable with, if not larger than, the damage done to the enemy. With an atomic warhead, however, the cost of the carrier is not excessive and even the expense of the most elaborate guiding and control equipment would not make the total product inefficient, for the destructive effect would exceed the total cost by a large factor.

Henry H. Arnold. 1949. *Global Mission.* New York: Harper. pp. 497.

Fortunately, judging from the mere 1100 that finally fell on England, chiefly London, the long-range V-2 rockets did not get into production until January, 1944. The planned output of 900 a month was not achieved, 50 to 300 being the number produced monthly until August. Between September, 1944, and March, 1945, the production rate was 700 a month. [...] A large bombproof launching site was under construction in France as early as May, 1943, however, and another in August, at about the same time the V-1 launching sites were begun. The V-10 (A-10), a very large rocket intended especially for New York, was being built.

[General Arnold would have had detailed classified knowledge of any wartime German development of intercontinental jet bombers, intercontinental rockets, and nuclear weapons. He stated unambiguously that the A-10 New York rocket was being built, and he confirmed that it was the same rocket as what had been called the V-10.]

Statement of Dr. Vannevar Bush to the U.S. Senate. 3 December 1945. *Hearings Before the Special Committee on Atomic Energy, United States Senate, Seventy-Ninth Congress, First Session, Pursuant to S. Res. 179, a Resolution Creating a Special Committee to Investigate Problems Relating to the Development, Use, and Control of Atomic Energy, Part 1, November 27, 28, 29 and 30, 1945. December 3, 1945.* Washington, D.C.: U.S. Government Printing Office, 1945, pp. 179–180. [Bush 1945]

Dr. BUSH. [...] Let me say this: There has been a great deal said about a 3,000-mile high-angle rocket. In my opinion, such a thing is impossible today and will be impossible for many years. [...]

They have been talking about a 3,000-mile high-angle rocket, shot from one continent to another, carrying an atomic bomb and so directed as to be a precise weapon which would land exactly on a certain target, such as a city.

I say, technically, I don't think anybody in the world knows how to do such a thing, and I feel confident that it will not be done for a very long period of time to come. [...]

The CHAIRMAN. Well, Dr. Bush, I read in this week's Collier's magazine an article by General Carl Spaatz of the Air Forces. I would like to have you read that article.

Dr. BUSH. That would not worry me in the slightest degree. I have just been criticizing the report of General Arnold of the Army Air Forces.

The CHAIRMAN. I wish that you would, sometime later on, comment on that article.

Senator TYDINGS. What does it say, Mr. Chairman?

The CHAIRMAN. What it says, Senator, is that the Germans, the year preceding the end of the war, were designing a rocket, and were pretty well along on it, that could carry from that continent to this continent and that would contain a warhead. They did not, of course, at that time have in mind an atomic warhead. That is my understanding of the article, at least.

Of course, I do not quality General Spaatz as an engineer, but he has written this article in Collier's.

Dr. BUSH. If you were talking about 400 miles or 500 miles, I would say by all means. That is what the Germans did with their V-2. I would say yes, even with 2,500 miles.

But 3,000 miles? That is not just a little step beyond, it is a vastly different thing, gentlemen. I think we can leave that out of our thinking. I wish the American public would leave that out of their thinking.

[Vannevar Bush, a doctor of engineering and vice president of MIT, created and ran the umbrella organization for all U.S. government-funded research and development during World War II (including the Manhattan Project), and developed the blueprint for postwar U.S. research programs (p. 2200). He had a deep personal knowledge of science and engineering, had access to the best scientists in the United States, and presumably had access to even the most highly classified information about what the United States had learned regarding German research and development programs.

Not only had Germany been developing long-range rockets during the war, but even as Bush gave this testimony to the U.S. Senate in December 1945, German-speaking scientists were hard at work in the United States, Soviet Union, and other countries to develop more rockets based on those wartime designs.

Because Vannevar Bush was so well informed and his other scientific statements were so accurate, it is striking that his statement about the feasibility of intercontinental rockets was so incorrect. He even ignored the evidence from U.S. Army Air Forces generals that was directly cited in this Senate hearing, insisting not only that intercontinental rockets were not feasible at the present time, but that they would not be feasible within the foreseeable future, and that no one in the world knew how to develop them.

Bush even went so far as to publicly state that it was entirely possible to increase the range of German rockets from the initial ∼190-mile range of the V-2 all the way to 2,500 miles (a 1200% increase), yet completely impossible to increase it just a little more from 2,500 miles to 3,000 miles (a further 20% increase). Such a statement seems scientifically ludicrous.

Was this a rare and extreme error by Bush, or was he intimately aware of the details of the German work—especially German work on 3,000-mile rockets capable of reaching the United States (e.g., pp. 5208, 5402, 5821)—and trying to cover it up in public? If he was trying to cover it up, what did he actually know? In retrospect, one gets the impression that whatever Bush had discovered about wartime German progress on intercontinental rockets (and/or atomic bombs they could carry) must have been sufficiently shocking for him to deny the topic so completely, despite so much evidence to the contrary.

The chairman of the Senate committee added that the Germans "did not, of course, at that time have in mind an atomic warhead." Yet that view was directly contradicted by the chairs of CIOS, U.S. General Thomas Jeffries Betts, Deputy G-2 of SHAEF, and U.K. Ministry of Supply chief advisor and F.R.S. Professor Reginald Patrick Linstead, in their written report (p. 5445). It was also contradicted by a great deal of other evidence that was known at that time to high-ranking U.S. officials (Appendix D and p. 5821).

Are any wartime and postwar papers by Vannevar Bush (and his chief deputies such as James B. Conant) still classified? If so, can they be declassified and searched for wartime or postwar intelligence on German programs to develop weapons of mass destruction and various means of delivering them to Allied targets?]

McNarney Predicts 10,000-Mile Missile. *New York Times.* 4 December 1948 p. 6.

Tell Industrialists Here That Tactics, Weapons of Last War Are Obsolete

Gen. Joseph T. McNarney, Commanding General of the Air Materiel Command at Wright Field, warned yesterday that while America must not consider itself prepared for push-button warfare, it "can no longer afford to fight a war of the future with the strategy, tactics and the conventional weapons of the last." [...]

In a graphic word picture of current developments in the field of rockets, jet propulsion and supersonic flight which he admitted was "fairly well fenced in by security restrictions," the general envisioned a missile with a 10,000-mile range that he held to be representative of future push-button warfare.

Guidance Critical Problem

The critical problem in the development of such a weapon, he declared, is guidance. As ranges increase, he added, the accuracy of radio and radar guidance schemes decreases. The optimum guidance system would be one that is self-contained within the missle and is non-jammable by the enemy, he said. [...]

The general pointed out that such a weapon is one of four types of guided missiles that military and scientific leaders feel will be successfully developed. Surface-to-surface missiles, he said, may be available in three years on America's shorter-range subsonic weapons, but he refused to predict the decade in which the nation will "cross the threshold of true push-button warfare."

Attack Possible "At This Hour"

In his review of the development of another one of the four guided missiles—the air-to-air missile—General McNarney said such a weapon would be effective in the event of an enemy bombing attack on a major American city. Such an attack, he warned, is possible "at this very hour when we consider the long-distance feats already accomplished by our own B-29 Superfortresses, which are even now being relegated to the realm of obsolescence."

The air-to-air missile, he explained, would be launched from interceptor aircraft and would proceed under rocket power at supersonic speeds, guided by a radar homing device at the enemy aircraft. Its development as an operational missile, he said, would take only a relatively short period of time. A surface-to-air missile, also moving at supersonic speeds after being fired from defensive ground sites, he added, "should be available for operational use within the next few years."

The general said that the development of air-to-surface guided missiles, or large bombs of the 12,000-pound, 22,000-pound and 43,000-pound class, designed to strike a specific enemy with high accuracy, is possible in the immediate future, with the 12,000-pound bomb being available within the next year. [...]

[Wright Field was home to vast quantities of documents and equipment captured in Germany, as well as many of the German aerospace engineers who came to the United States. This report may reflect wartime German accomplishments, and in any event shows how deeply indebted postwar U.S. programs were to German creations and creators.]

Germans Had Jet 'Planes 5 Times Faster Than Sound.' *The Ottawa Journal.* 18 January 1946 p. 9. [**https://www.newspapers.com/newspage/50100865/**].

A jet aircraft designed to travel at five times the speed of sound and a rocket motor 10 times larger than those used on V-2s at the end of the war were just two of many German developments in aeronautics viewed by Canadian-scientists during a recent tour of the battered Reich. The experts, five members of the National Research Council Staff, spent four months poking around former German research stations, airfields and underground factories. At a symposium of the Council's Science Association they reported their conclusion that many advances in German aeronautics failed to reach the production stage, only because of Hitler's "intuition and interference" and a lack of co-ordination of various projects by the Nazi air ministry. The experts were W. F. Campbell, wind tunnel expert; R. D. Hiscocks, supervisor of the airframes laboratory; M. S. Kuhring, chief of the engine laboratories; J. L. Orr, in charge of de-icing research, and D. G. Samaras, another engine expert. Mr. Samaras reported the Germans had made "considerable headway" in trans-Atlantic rockets and actually were making preparations for space travel. A lack of materials, skilled labor and proper organisation slowed this project. In rockets and jet propulsion, the Nazis had "10 times our technical facilities" and in rocket research were "miles ahead of us." Research now was extensive in Britain and the United States in this field and it was time similar work was started in Canada. Mr. Hiscocks described several advanced types of jet and propeller-driven aircraft with most of the later models featuring "sweep back" wings.

The most advanced was a fantastic jet affair resembling a paper dart, called the [Lippisch] DM-1. It was a modified glider designed to reach speeds five times faster than sound and operate at an altitude of up to 22 miles. "It was completed just in time for the United States Army to take delivery," he said. Another type in the 600 mile-an-hour bracket resembled a boomerang with a jet engine mounted in the centre. It had a 50-foot wing span and could remain in the air for three to four hours "high for a jet." Another novel feature was a "pilot ejector seat," which broke an air vice-marshall's back when he ventured to test it. Some Messerschmidt 262's had rocket boosters enabling them to climb 30,000 feet in two minutes. A late model Heinkel 162 had a climbing rate of 4,200 feet a minute and sufficient were produced to take "quite a toll of our bombers." Still another type was a tailless rocket job, "the first in the world." It had a speed of 600 miles-an-hour and climbed 30,000 feet in 2 1/2 minutes. The German scientists "knew about as much about air foils as we did," but went farther in designing wings that sweep back sharply from the nose of the aircraft. Such designs give as much as a 60-mile-an-hour boost to speeds, but lack control at lower speeds.

"Hitler's visions disrupted the whole aircraft production program," Mr. Hiscocks said. Once the German leader ordered a plane designed as an interceptor to be converted into a bomber. Mr. Hiscocks said the Germans never produced an outstanding bomber. In general the failure of Germany to win control of the air was "a tactical error by the high command and not the fault of the designers." The world's first jet plane had been flown at Rostock in 1938, about a year ahead of the first Italian effort and three years ahead of Britain.

[Five Canadian aerospace experts reported that while visiting a German research station, they viewed "a rocket motor 10 times larger than those used on V-2s." The most important parameter of a rocket motor is its thrust; if that is the measure of comparison intended here, the standard V-2 motor had a thrust of 27 tons at sea-level atmospheric pressure, so that would mean the Canadians saw a rocket motor with a thrust of roughly 270 tons. Both the A-10 booster and the Silbervogel space plane were designed to use engines with a 200-ton thrust. Thus the reported engine could have been built specifically for either one of those vehicles, and would demonstrate that those projects had progressed well beyond the paper design phase. Alternatively, the reported engine could have been for some other large rocket project that has been even less well characterized in the published literature.

If the reported motor was "10 times larger" in mass, a standard V-2 motor had a mass of approximately 930 kg, so the observed motor would have had a mass of roughly 9300 kg. The best documented design for an A-10 motor used six standard V-2 motors that all fed into a larger nozzle. The A-10 engine mass does not seem to be reported in the published literature but would have included the mass of the six standard motors plus almost as much for the large nozzle, or roughly 10 times the mass of one standard V-2 motor. Likewise the exact Silbervogel engine mass is difficult to find, but a reasonable estimate is that it was roughly half of the 10,000 kg empty mass of the Silbervogel, or roughly 5000 kg.

Conceivably the reported motor might have been "10 times larger" than a standard V-2 motor in length, width, combustion chamber volume, nozzle area, or some other parameter.

In any event, the report by the Canadian aerospace experts demonstrates that some very large rocket project had progressed well beyond the drawing board: A-10, Silbervogel, or some other rocket similarly sized for intercontinental trajectories.

Can the detailed scientific reports of these Canadian experts be located?

Donald L. Putt. 1946b. German Developments in the Field of Guided Missiles. ***Society of Automotive Engineering (SAE) Journal (Transactions)*** **54:8:404-411.**

[...] After watching the V-1 and V-2 firing trials at Blizna and Cracow, Poland, in April, 1944, Hitler is reported to have stated that German secret weapons were not the product of dreamers and that England and the whole world would soon feel their effect. It wasn't until allied technicians examined German developments in this field that we fully realized the tremendous achievements of German scientists, and how near they were to achieving the boasts of their leader.

The Germans were preparing rocket surprises for the whole world in general and England in particular, which would have, it is believed, changed the course of the war if the invasion had been postponed for so short a time as six months. Many of Germany's research laboratories and several large commercial firms concentrated on this field of endeavor. This tremendous effort resulted in 138 guided missiles and assorted devices, including their modifications. These were of types wholly unknown to laymen in the United States. At the outbreak of the war some of these were strictly "out of this world"—to use a current phrase. In addition, German scientists had developed other equipment of a type we had considered impracticable, such as the ram jet.

The stupendous effort in basic research expended by the Germans in the guided missile field was designed to cover the complete field of potentialities for such weapons. The losses incurred in Germany by heavy bomber raids can in no way be charged to lack of preliminary research on missiles. Weapons of this category were divided into the following classifications:

A. Ground to air.

B. Air to air.

C. Air to ground.

D. Ground to ground.

E. Underwater to underwater.

F. Underwater to ground.

G. Underwater to air.

Moreover, every known type of remote control and fusing means was exploited. These included radio control, wire control, radar, continuous wave, acoustics, infrared, light beams, and magnetics.

Likewise, all methods of employing jet propulsion for subsonic and supersonic speeds were exploited.

In all, it was estimated that one-third of the aerodynamics research in Germany was devoted to problems of guided missiles. Wind tunnels of undreamed-of speeds were under construction. A Mach number of 10 was not too great for the Germans to comprehend and strive for.

In the matter of aerodynamics and propulsion, the Germans were sufficiently advanced to handle any program desired. In the field of control they appear to have waited too long to make the necessary tests to indicate the proper directions for detail development; also, the fact that the Germans were late in being able to arrive at the answers required to utilize nuclear energy in the warheads made the German missile program more one of nuisance and worry over what might come than one of actual military damage.

Some of the classes of German missiles based on intended use are:

A. The Beethoven [...] was an air-to-ground missile. This composite aircraft consisted of an Me-109 fighter mounted on top of a Ju-88 bomber. The pilot rode in the cockpit of the Me-109, where he manipulated the controls of both craft. The nose of the Ju-88 was modified to contain an explosive. Upon reaching the target area the Ju-88 was released from the Me-109 in a dive which aimed it at the objective. This weapon was not used by the Germans to any extent; however, upon the termination of hostilities it was found that great quantities had been built up for an all-out assault at a later date.

B. The Enzian [...] was a ground-to-air missile. This small-winged flak rocket, named after the flower gentian, was controlled in flight by radio, and was intended for use against heavy-bomber formations. Its plywood fuselage was 17 ft in length and carried 990 lb of explosive. Four auxiliary starting rockets were mounted outside the fuselage, and after 5 sec of flight were jettisoned. Plans were being made to modify the Enzian so that it could attain supersonic speeds, but because of the advances of the U.S. Army only a few successful test firings were made.

C. The Wasserfall was a ground-to-air missile. A 26-ft flak rocket, the Wasserfall, meaning waterfall, is very similar in design to the V-2 rocket launched against Britain. At first it was visibly controlled by radio from the ground, but later methods employed radar tracking to guide it to the objective. Due to persistent allied bombing only 30 test launchings were made.

D. The X-4 was an air-to-air missile. It was a small rocket bomb, named Ruhrstahl or steel of the Ruhr, just under 6 ft in length, and designed to be launched from fighter aircraft. The rocket was controlled from the parent aircraft through two 4-mile lengths of wire. This fine wire was paid out from tapered bobbins enclosed in fairings at the extremities of two of the wings. Detonation occurred by means of a proximity fuse.

E. The Fitz X [...] was an air-to-ground missile. This German bomb was released from aircraft flying at a minimum altitude of 22,000 ft. It was gyrostabilized and visibly guided into the target by radio. The Fritz X was ready for operational use in January, 1943, and was first employed successfully against our shipping and assault forces at Salerno. The warhead on this bomb was armor-piercing and carried a charge of 2530 lb of standard explosive.

F. The Hs-298 [...] was an air-to-air missile. It was about 4 ft in length and could be controlled either by radio or wire. It was originally intended for use against sea targets, but early in 1945 it was being produced for air-to-air fighting in a factory in the underground railway in Berlin. A total of only 300 was built because the X-4 or Ruhrstahl bomb had become available.

G. The Hs-117 [...] was a ground-to-air missile. It was named Schmetterling or butterfly, and was a rocket-propelled, radio-controlled missile to be launched from the ground against bomber formations. It accelerated to a speed of 560 mph, and was steadied in flight by a pendulum device. The take-off rocket burned out and were jettisoned; the main propulsion unit then drove the missile until it was detonated by a proximity fuse. Large-scale production began January, 1945, in an underground factory in Nordhausen.

H. The Rheintochter [...] was a ground-to-air missile. It was a rocket-propelled anti-aircraft weapon and was controlled in flight by radio. It traveled at a speed of 1100 mph and carried an explosive charge of 330 lb, equipped with a proximity fuse, to a ceiling of 48,000 ft. The starting rocket, attached to the base, was blown off after combustion was completed. Development did not go beyond the test firing stage, but experiments were still being conducted as late as February, 1945. The code name Rheintochter means daughter of the Rhine.

I. The FZG-76 [...] was a ground-to-ground missile. It was launched either from the ground or from an aircraft. Ground launching as practiced by the Germans utilized a long run in which the working substance was the steam resulting from the catalytic action of calcium permanganate on a concentrated solution of hydrogen peroxide. The length of the gun and ramp varied from 140 to 170 ft at different sites. It carried 1870 lb of explosive, the range was 120 to 160 miles, and the circular probable error about five miles at a range of 130 miles when ground launched. The error was five times as great for air launching. The overall weight was about 5000 lb. The missile flew at an approximately constant altitude of about 2000 ft at speed varying for individual missiles from 288 to 425 mph.

Numerous techniques for controlling the missiles were evolved, only one or two of which proved satisfactory. Conventional radar units, with special coding mechanisms were used. In one instance a beam-riding system was attempted, but the disastrous test results caused an immediate cessation of the project. It appears that the missile was supposed to follow a beam of energy emanating from a radar unit and aimed at the target, in this case an airplane; however, the missile would usually reverse its direction and ride the beam down to the radar unit, with quite obvious results. As a result, it was decided to augment the control system by adding homing or seeking devices of various sorts. These included systems sensitive to heat or sound. Some of the homing devices incorporated a miniature radar unit.

The German developments being discussed here are generally grouped under the loose term “guided missiles”; however, that isn’t correct, inasmuch as some of the missiles are not guided and some of the developments are not missiles. I have already discussed another widely employed classification based upon the location of the launching device and the target; for example: air-launched-to-ground targets. The classification I shall employ is based upon the type of propulsion unit.

There are six general types of direct-reaction engines.

1. The first example is the reciprocating engine with the exhaust jet.

2. The second example is the gas turbine.

3. The third example is the turbo jet.

4. The fourth example is the reed, intermittent-combustion engine. This is better known as the "buzz bomb" engine. The reed engine is similar to the ram jet engine, with the exception that it is equipped with a grill at the forward end.

5. The fifth example is the ram jet, also known as the athodyd or the Lorin engine, after the inventor. This device consists primarily of a curved, barrel-like tube into which fuel and air are introduced.

6. The sixth and last example is the pure rocket. This is subdivided into the dry fuel and liquid fuel subtypes. In either case, we have simply a combustion chamber in which the fuel burns. In the case of the dry fuel rockets, the fuel is also stored there. A great many of the German guided missiles were equipped with this type of propulsion equipment.

This discussion concerns itself with the latter three listed propulsion systems. For the purpose of simplicity, we will now consider the various engines and their applications, commencing with the reed engine and the ram jet. We have but one example of each of these, whereas we have some 30 examples of the rocket type. [...]

The next type of engine we will consider is the ram jet.

Only quite recently, now that air-speed values are approaching the velocity of sound, has it been practicable to envisage the use of the Lorin nozzle for propulsion. In the fall of 1944, while development in this country was largely limited to discussion as to whether such a powerplant would operate at all, the Germans had developed, built, and flight-tested a unit designed to produce a gross thrust of 4400 lb at 500 mph. (See Fig. 9). This development was accomplished by Walter of Kiel, Dr. Saenger of the DFS (Institute for Study of Soaring Flight), and by engineer Pabst of the Focke-Wulf plant at Bad Eilsen. [...]

A particularly effective employment of the Lorin tube is that of a jet propeller with a rotating wing. [...] Here characteristics and performance are very high; particularly in the range obtained at high altitudes. This is due to the fact that in rotating-wing aircraft the rotors can always be run at suitably high speeds. A rocket attachment can be provided to enable safe landing if the propellers are cut off. Take-offs and landings in these aircraft occur vertically, and only a small flying strip is required. [...]

The most highly publicized missile of the Germans was the V-2, or as the Germans themselves knew it, the A-4.

There were 10 variations of this weapon. [...] Three were prototypes. Four were improved models. One was a launching device intended to increase the already great range to 5000 km. Interestingly enough, one of the improved models was to be equipped with wings, wheels, a pressurized cabin, and to carry a pilot. [...]

The "A" series was considered to be an intermediate step to the practical use of guided weapons. The inherent shortcomings of this type of weapon were partly conditioned by the war, but the future will disclose improvement occurring more rapidly than was thought possible prior to the war.

It is interesting to note that this missile was extremely expensive, each requiring 20,000 man-hr for construction; however, since the Germans launched 3165 A-4's operationally, it is clearly indicated that the place of the large rocket weapon is firmly established in modern warfare. It has been pointed out that the small size of the warhead—1 ton—would hardly seem to have made the cost of the weapon worth while. In this connection it must be pointed out that it was probably the intention of the Germans that the weapon would eventually carry some sort of atomic device, in which case the warhead would have had the requisite specifications. [...]

In conclusion may I state that the Germans in the guided missile field were 10 years in advance of similar American development.

It will be noted that the Germans very largely explored the entire field of rocket-powered equipment. Their program was just beginning to become stabilized with the production of those units which were adaptable to mass production and operational use.

Very fortunately, they were never able to obtain full use of their developments. We are all familiar with the immense rocket-launching establishment on the coast of France which was to be used in destroying London.

It is now the responsibility of the American industrial machine to begin where the Germans stopped and to provide ourselves with the equipment necessary to maintaining our leadership in the scientific world.

American industry and the War Department must cooperate in exploiting this field, in which there appear to be unlimited possibilities for new and better devices and equipment, not alone in the province of weapons of war, but also in the applications to a fuller and more satisfactory civilization. [...]

[Note the similarities between Putt's presentation and the earlier reports on pp. 5429 and E.2 with which he was probably intimately involved. Putt was the U.S. Army Air Forces Colonel (later General) in charge of rounding up most of the German aerospace engineers in Europe at the end of the war, and funding them to continue their work in the United States for many years after the war. From that very well-informed position, he stated in this 7 March 1946 presentation to the Society of Automotive Engineers that among other things:

- German engineers had developed "the complete field of potentialities" of all possible types of missiles, "every known type" of electronic guidance and sensors, and jets and aerodynamics ranging from subsonic through supersonic speeds to Mach 10, or 10 times the speed of sound.
- Based on his studies of this field, the Germans were fully ten years ahead of the United States.
- There were many different types of long-range rockets. Putt's brief description of "10 variations of this weapon" could be taken to mean the well-known series from A-1 to A-10, or it might have reflected other variations that Putt had seen during his investigations of German rocket programs.

- Germany was within six months of employing rockets with much greater range than the A-4 (V-2) that would have "changed the course of the war," which would suggest that such rockets had already progressed well beyond the paper design stage.

- He believed that the Germans intended to put nuclear weapons on their rockets, which would suggest that there had been a long-running and determined nuclear weapons program operating in parallel with the German rocket program.

Interestingly, some of these statements vanished without explanation from later versions of this speech, such as the 27 June 1946 version written at Wright Field, possibly due to censorship. Censorship may also explain why he publicly stated much less than he presumably knew about the A-9/A-10 intercontinental rocket or other long-range rockets that were on the verge of changing "the course of the war." Senator Elbert D. Thomas. April 1946. Sitting Ducks in Our Air Forces. *The American Magazine.* pp. 26–124.

We won the air war against the Germans with muscle, not mind. We smothered them with the sheer weight of our planes. Their air weapons were ahead of ours at the start of the war, and far ahead at its end. Had our invasion of Europe been delayed six months, we might have lost the war, due to our inferiority in the air.

For years our Air Forces have given the American public a false sense of security by untruthful boasting. Before the war, we were told that American air power was best. It wasn't. . . . During the war, we were told that it was both best and biggest. It wasn't best; it was just biggest; it was muscle not mind. . . . We'd better learn the truth. For in the next war—God forbid!—boasting won't count, and there will be no time to build mere muscle into victory, as we did this time. Mind, not muscle, will win, and in days or hours instead of years.

Our combat airmen, the fighter pilots and bomber crews, fought magnificently with the weapons given them. But they weren't the best weapons, as they should have been. Our Air Forces high command clung stupidly and stubbornly to the ideas and weapons of yesterday, while the Germans developed and put into combat those of today and tomorrow.

After V-E Day, Allied civilian scientists and engineers visited Germany and inspected the laboratories, experimental stations, and factories which served the Luftwaffe. Their findings show not only the superiority of new German weapons, but the details of Germany's long-range research and development, a program marked by vision and eagerness to try new ideas. By contrast, the findings reveal our Air Forces' appalling lack of vision and stubborn allergy to new ideas, which were concealed from the American public. [...]

They [Germans] were first in combat with pressurized cabins, essential to high-altitude flight; with pilot-ejection, a mechanical bailout vital to high speeds and altitudes; with special high-altitude parachutes; with unified engine-control, needed by fighter pilots; with plane-to-plane rockets; with a true aircraft gun, a cannon ten times as destructive as our comparable cannon. [...]

The real shock comes when we view the Germans' unconventional developments, their really new ideas and weapons. They had most of them in combat. We had a few in partial development, none in combat. While we were being told what our new weapons were *going* to do, the new German weapons were *doing* it. [...]

This was the Messerschmitt-262 jet-propelled fighter, which first appeared in combat in the summer of 1944. Making 525 miles per hour, it was much faster than our Mustangs, Thunderbolts and Lightnings. At sea level it was *more than 150 m.p.h. faster.* [...]

Another German jet plane, the Heinkel-162 *Volksjaeger* (People's Fighter) had about the same performance. Still another, in development, was the *Triebfluegel Flugzeug* (powerwing aircraft) which had 3 wings radiating from the fuselage, like the fins on a bomb. Each wing-tip carried a jet engine. Launched vertically and shot to high altitude by rockets, its 3 jets would make it extremely fast in combat.

The Germans had jet bombers, too. The Arado-234 was made in 2 models, with speeds of 470 and 546 m.p.h. The Junkers-287, in flight test when the war ended, had more than twice the power of our B-29 Superfortress, could carry as many bombs to London as a B-17 could carry to Berlin, and made 537 m.p.h. There was to be a Junkers flying wing, with 4 jet engines and a speed of 620 m.p.h.

Even their jet bombers were *faster than our fighters*, making interception difficult and pursuit impossible. Our tactical commanders never understood why German jets, fighters, and bombers didn't raid southern England. They had the range and would have found hundreds of airfields crammed with our planes. With their great speed, they would have suffered little from antiaircraft fire. Our fighters couldn't have coped with them. Such raids would have been utterly devastating.

German rocket fighters, in combat during the last six months of the war, were even faster than the jets. One model of the Messerschmitt-163 made 550, another 590, m.p.h.

The Bachem *Natter* (Viper), in development, was launched vertically to get upstairs fast and attack bombers with rockets, and by ramming after its pilot was ejected. Though test-flown, its maximum speed was still estimated, but at more than 600 m.p.h. [...]

The V-1 made 360 m.p.h. at 3,000 feet altitude or less. Our fighters had to dive from higher altitude to catch it. [...] In terms of time and bomb-tonnage, the V-1's were much more destructive than Allied bomber raids on Germany. And much cheaper. [...]

The V-2 was still more spectacular—a rocket 45 feet long, 5 feet in diameter, weighing 12 tons, and carrying a ton of high explosive. [...] It was 6 times as fast as the German jet and rocket planes, traveling about 3,600 m.p.h. Far from catching it, our fighter pilots couldn't even see it. [...]

About a dozen new V-weapons were on drawing boards, in laboratories, and nearing production. One would carry troops in a pressurized cabin. Another would be launched from a submarine 300 feet below the surface. A third would cross the Atlantic in 14 minutes, arching to 500 miles' altitude and flying at 16,000 m.p.h. It was intended for morale-shattering mass raids on New York. It wasn't impractical. The Germans' prediction that they would do it in a year or so was no idle boast.

Had our invasion been delayed six months, the Germans could have regained air superiority, not only in Europe, but over the Channel and southern England. We could have continued night raids, but our daylight raids would have been suicidal. They could have raided England both night and day. Our planes couldn't have stopped them. Striking at airfields, troop-concentration areas, ports, and shipping—decimating our armies and destroying their equipment—they could have made an invasion of Europe almost impossible. Their better planes could have destroyed ours on the ground, as ours did theirs when muscle outweighed mind.

Between raids by their planes there would have been thunderous barrages of V-weapons. They planned to launch 1,000 V-1's a day. Rockets more deadly than the V-2 would have reached north to all important cities in England. We couldn't have prevented it.

England would have been pounded to rubble. Even if the Germans didn't invade, and they might have, a stalemate and negotiated peace would have been our best prospect, and total defeat not at all unlikely. We had a narrow escape, as it was. After our ground forces conquered the Continental coast just before V-E day, I visited a V-weapon factory. I could not help but utter to myself, and I've repeated it often, "We are just in time." That was no flight of poetic oratory; it was the stark and awful truth. And the threatened defeat which it so clearly implied *would have been due directly to our backwardness in the science of aviation.*

With more appetite for publicity than respect for the truth, our Air Forces brought us to World War II believing that we were the world's leading military air power. Press-agent activities produced such magazine articles as *Our Own War Birds Are Best*, in 1939. They weren't; they were inferior in speed, altitude, firepower, armor, and other respects. Commenting on this in 1942, a Congressional report said, "All this, despite the fact that Congressional Committees were frequently told our war planes of that period (1939) were better than those of other nations."

There was no secrecy about the Germans' superiority. They described and illustrated their planes in books and magazines, discussed them on the air and invited foreign pilots, including ours, to inspect and fly them.

Yet during the war hundreds of press agents, advertising men, and others more or less skilled at deceiving the public were hastily commissioned as Air Forces public-relations officers. Combat results, especially in bombing operations, were grossly exaggerated. Scores of enemy strong points were "wiped out" on Monday and "obliterated" on Tuesday, only to offer the bloodiest resistance to our ground forces on Wednesday.

On the home front, newspapers were deluged with misleading handouts. Magazine writers were given similarly misleading information about planes and equipment. Thousands of radio programs went on the air from hundreds of stations, with similar disdain for the truth. [...]

During and immediately after the war the new German weapons—jet and rocket planes, V-1's and V-2's—were ignored or belittled as "weapons of desperation," "fantastic," or "on the lunatic fringe," though anyone who thought so was clearly on the lunatic fringe, himself. Once the weapons were in our hands, the fashion changed. Recent articles discussed them seriously as weapons in our own air arsenal, but their German origin has never been denied. [...]

The Germans produced the weapons of today and tomorrow, while we improved those of World War I.

The defense usually offered by the Air Forces when charged with lack of progress is that they "weren't given enough money." That is largely nonsense. [...] The millions spent on most of these minor improvements, or failures, with propeller-driven planes would have produced jet planes. It was vision, not money, that was lacking. [...]

A change in leadership is not the solution of the problem. The truth is that our Air Forces suffer the ailments common to all military self-perpetuating organizations—ruling cliques, caste, politics, petty bureaucracy, fixed regulations, the purely arbitrary authority of rank and seniority, promotion for these reasons more often than for genuine ability. All these factors encourage acceptance of the past and discourage vision for the future.

[As previously noted, standard A-4 or V-2 rockets required over five years of massive effort to progress from paper designs to deployed weapons, carried one ton of conventional explosives, and could not reach England from areas still under German military control near the end of the war.

Based both on Senator Thomas's on-site inspections of German rocket programs and on his knowledge of detailed reports from scientific inspectors, he stated that Germany was within six months of deploying mass-produced versions of much more advanced rockets that were "more deadly than the V-2" (apparently meaning with payloads that were much more destructive than conventional explosives) and would have enough range to reach all of the United Kingdom from central Europe (with a much longer range than the V-2).

He also mentioned at least three other advanced types of rockets that (1) "would carry troops in a pressurized cabin," (2) "would be launched from a submarine 300 feet below the surface," and (3) "would cross the Atlantic in 14 minutes."

Senator Thomas and the other inspectors could not possibly have expected those more advanced rockets to make the leap from paper design to mass-produced deployed weapon in just six months; most likely the inspectors discovered well advanced hardware development, testing, and/or production programs for the rockets.

Senator Thomas's description of the 1940s U.S. research system seems to still be quite applicable to the modern research system.]

U.S. Army Ordnance Department. 1946. ***History of Ordnance Technical Intelligence in World War II, Part 1: History, Orders & Circulars, Publicity.*** **[https://digitalcommons.unl.edu/cgi/viewcontent.cgi?article=1059&context=dodmilintel]**

During the war, American Ordnance was tested in deadly combat against the greatest array of enemies to oppose us in all history. They were armed with weapons which were the products of years of planning and building and the best that their mobilized scientific talent could devise. Nor did they stand still—for they realized that they were in a desperate competition wherein other things being equal, the nation which led in the design and production of the most deadly weapons would win. The most obvious example of the truth of this is the atomic bomb. However, this cannot be considered the only example that has appeared in this war which has seriously affected its outcome as there have been many other cases—like that of proximity fuzes and radar.

In connection with the subject of proximity fuzes, the Germans had expended a vast amount of energy on the research and development of fuzes which would detonate ammunition without coming in physical contact with the target. We were far ahead of them on actually getting a proximity fuze into production and into active use during the war, they were very effective, particularly in antiaircraft use. However, at the time the war ended, the German research and development had progressed to such an extent that they had designs almost ready for production and had thoroughly investigated many of the possible types of proximity fuzes; e.g. acoustic, radio, photo-electric and electro-static types.

This same situation occurred in many other fields of ordnance where the Germans were advancing very rapidly at the end of the war, and had the war lasted much longer, some of the new designs may have had an effect on prolonging the war. This possibly is most evident in connection with guided missiles.

Probably because of their lack of aircraft there was a tremendous incentive to develop some kind of a weapon to combat our devastating bombings. A number of rocket propelled missiles which could be guided from the ground and which would detonate by the use of a proximity fuze when coming within the danger area of one of our airplanes were developed to the production stage and one guided missile was actually in production at the end of the war. Our understanding of the way one was to have operated was by means of radar screen which could track both the target and the missile. The operator would have the necessary controls required to direct the missile and by watching the radar screen could take the necessary steps to bring the missile as close as possible to the airplane, at which time the proximity fuze would function and the airplane would disappear.

Quite a number of types of the well-known V-2 rocket had been worked on by the Germans and the research progress was laid out in such a manner that it would appear that very long range rockets might have been used some time in the near future had the war continued and nothing else interfered with their efforts. It is frightful to consider the possibility of a guided missile with an atomic bomb as a warhead, but there is little doubt that the Germans were actively considering the possibilities of such a weapon.

[The U.S. Army Ordnance Department closely investigated advanced German weapons both during and after the war. The Ordnance investigators were actually reprimanded by General Leslie Groves for publicly revealing how advanced the Germans were. See pp. 4186–4187, 5747–5753.]

[See document photo on p. 5483. This AFHRA file folder and the corresponding microfilm reel only include this cover letter, not the actual report. Can this report be located in archives at AFHRA, NARA, Wright Patterson Air Force Base, or elsewhere?

What exactly did Hugo Kalinourski and Max Gorissen work on during the war? What did they do for the United States after the war? Was this a report of their own work, or a report or translation they wrote based on the work of other German engineers?]

Card catalog entry for *History of German Trans-Atlantic Rocket A-10.* 4 March 1947. [NARA RG 319, Records of the Army Staff, Entry A1-84E, Box 124. BID 8600.0711 Nuclear Physics (Atomic Energy)—Uses—Rockets]

[The photographs from a U.S. Army card catalog of intelligence documents on p. 5485 show that the U.S. government once possessed a complete history of the A-9/A-10 trans-Atlantic rocket, written two years after the war's end, but that this history was either destroyed or not transferred to NARA with the other files; no copies of this report have ever been located. If the A-9/A-10 never entered active development during the war, why would the U.S. government have commissioned a detailed history of its development in 1947, and why would the government have later ordered that history to be suppressed? Does the fact that the Army Assistant Chief of Staff for Intelligence specifically filed this report under "Nuclear Physics (Atomic Energy)—Uses" indicate that the A-9/A-10 had a nuclear warhead? CIG, listed as the source of the report, was the Central Intelligence Group, a U.S. intelligence agency that existed during 1946–1947 as an intermediate step between the wartime Office of Strategic Services (OSS) and the modern Central Intelligence Agency (CIA). Charles J. V. Murphy. The State of the Armed Forces. *Life.* 2 Sept. 1946, pp. 96–108. https://books.google.com/books?id=OEIEAAAAMBAJ&pg=PA96&source=gbs_toc_r&cad=2#v=onepage&q&f=false

Yet, as matters stand now, the most important question mark in the U.S. military equation is not the conflicting rate of development of the supersonic airplane and its counter. It is whether the big, long-range supersonic rocket, such as the German V-2, will develop to a point where it will supplant the strategic bomber.

The V-2 now being tested in the New Mexico desert is, by bombsight standards, an inaccurate and unreliable weapon. On a 200-mile range it is seldom accurate within six miles. It consumes about nine tons of alcohol and oxygen to deliver a ton of explosives. But it would be a dull man indeed who considered these shortcomings decisive. As a mechanical proposition, the rocket offers the most effective way to deliver the atomic bomb. Its plunging descent at ultrasonic speed (maximum: 4,400 feet per second) makes the problem of radar tracking and interception as agonizingly difficult as coping with the atomic explosion itself. In fact, even now the 1945 model of the German V-2 with a non-atomic warhead and a 350-mile range (unfortunately none of the samples fell into our hands) has been conceded by the British Imperial Staff as rendering the British Isles indefensible. [...]

Not insignificantly the common language in the assembly sheds at White Sands is German. The fact of our dependence upon German scientists in this epochal development in the art of war explains in large measure the unprecedented preoccupation of our military planners with pure research. For in many fields of research—guided missiles (of which they invented 138 types), supersonic flight and submarine warfare—the Germans were far ahead of us. The real reparations prize of the war was not German machinery but German brains and research records.

Under the Potsdam partitioning of Germany, the Russians ended up with all the guided-missile proving grounds and most of the factories, the principal supersonic research centers (with wind tunnels far in advance of our own) as well as the underground mass-production and V-2 plant at Nordhausen. Equally precious were masses of official records, of which the some 400 tons plucked out by a handful of American intelligence officers represent but an inadequate sampling. Chance delivered into our hands the two leading V-2 research men, but the rank and file of German technicians in nearly all branches of the war sciences—nuclear physics, jet propulsion, supersonics and so on—were left in the Russian zone. The Russians have not only put them to work, but they have begun to coax across the Elbe scientists and other technicians from the American and British zone. Top-flight men are being offered the equivalent of $35,000 a year, with assurance of freedom of research and of person.

The possibility that these wandering talents, embodying billions of dollars worth of research knowledge, may drift into Russia worries U.S. strategists far more than the stripping of German machinery. An American general observes, “These German scientists are the new mercenaries.” [...]

And they give point to the observation of Rear Admiral Luis de Florez, the Navy’s assistant director of research: “If we had only been smart enough to grab Germany’s top 1,000 scientists and technicians and cart them off to a kind of scientific St. Helena, Europe would have remained disarmed for a generation.”

[Charles J. V. Murphy (U.S., 1904–1987) had a long career as a journalist specializing in intelligence and defense for *Time*, *Life*, and other publications. He also served as a colonel in the Air Force Reserve after WWII and handled public relations and speechwriting for many Air Force and NATO officials. Thus he was incredibly well connected and extremely knowledgeable regarding military technologies. For more information on Murphy, see:

https://www.washingtonpost.com/archive/local/1987/12/31/author-and-journalist-charles-murphy-dies/0c630636-8b51-4715-971d-3c64a75d5b99/

In this *Life* article, Murphy clearly stated the usual 200 mile (∼320 km) range of a standard A-4 (V-2) rocket. Then he stated that there were multiple copies of an improved “1945 model” of the rocket with a 350 mile (∼560 km) range that existed at the end of the war but were not seized by U.S. forces. From other information in the article, it sounds as if they were seized by Soviet forces. While 350 miles is much longer than the range of a standard 14-meter-long A-4 (or its postwar Soviet copy, R-1 or SS-1), it is a perfect match for the range of an upgraded 18-meter-long A-4 like the postwar Soviet R-2 or SS-2. Thus the information in this article suggests that upgraded 18-meter A-4 rockets had already been mass-produced by Germany during the war, were taken by Soviet forces at the end of the war, and were copied as the Soviet R-2 or SS-2.

A number of independent sources also indicated that upgraded 18-meter-long A-4 rockets were produced in Germany during the war (p. 5794).

Where are the German documents on these improved rockets? Note that Murphy specifically mentioned “400 tons” of captured German documents that were especially relevant.

Where are the Allied reports on the advanced rockets, or postwar interrogations of Germans who had worked on the advanced rockets?

Where are the documents in which the British Imperial Staff “conceded” these existing German rockets “as rendering the British Isles indefensible?”

Admiral Luis de Florez headed research programs in the U.S. Navy during and after WWII, and in the CIA after the war. From that highly informed position, he voiced his opinion that the top 1,000 scientists in the world who were capable of creating revolutionary military technologies were all German.

The rest of the article, supported by Murphy’s highly placed sources in the U.S. military and intelligence communities, confirms that German-speaking scientists and their technologies were far ahead of those that had been home grown within the United States up to that point.]

Charles Lester Walker. October 1946. Secrets by the Thousands. *Harper's Magazine* 193:329-336.

But of highest significance for the future were the Nazi secrets in aviation and in various types of missiles.

"The V2 rocket, which bombed London," an Army Air Forces publication reports, "was just a toy compared to what the Germans had up their sleeve."

When the war ended, we now know, they had 138 types of guided missiles in various stages of production or development, using every known kind of remote control and fuse: radio, radar, wire, continuous wave, acoustics, infra-red, light beams, and magnetics, to name some; and for power, all methods of jet propulsion for either subsonic or supersonic speeds. Jet propulsion had even been applied to helicopter flight. The fuel was piped to combustion chambers at the rotor blade tips, where it exploded, whirling the blades around like a lawn sprinkler or pinwheel. As for rocket propulsion, their A-4 rocket, which was just getting into large scale production when the war ended, was forty-six feet long, weighed over 24,000 pounds, and traveled 230 miles. It rose sixty miles above the earth and had a maximum speed of 3,735 miles an hour – three times that of the earth's rotation at the equator. The secret of its supersonic speed, we know today, lay in its rocket motor which used liquid oxygen and alcohol for fuel. It was either radio controlled or self-guided to its target by gyroscopic means. Since its speed was supersonic, it could not be heard before it struck.

Another German rocket which was coming along was the A-9. This was bigger still—29,000 pounds—and had wings which gave it a flying range of 3,000 miles. It was manufactured at the famous Peenemünde army experiment station and achieved the unbelievable speed of 5,870 miles an hour.

A long range rocket-motored bomber which, the war documents indicate, was never completed merely because of the war's quick ending, would have been capable of flight from Germany to New York in forty minutes. Pilot-guided from a pressurized cabin, it would have flown at an altitude of 154 miles. Launching was to be by catapult at 500 miles an hour, and the ship would rise to its maximum altitude in as short a time as four minutes. There, fuel exhausted, it would glide through the outer atmosphere, bearing down on its target. With one hundred bombers of this type the Germans hoped to destroy any city on earth in a few days operations.

Little wonder, then, that today Army Air Forces experts declare publicly that in rocket power and guided missiles the Nazis were ahead of us by at least ten years.

The Germans even had devices ready which would take care of pilots forced to leave supersonic planes in flight. Normally a pilot who stuck his head out at such speeds would have it shorn off. His parachute on opening would burst in space. To prevent these calamitous happenings an ejector seat had been invented which flung the pilot clear instantaneously. His chute was already burst, that is, made of latticed ribbons which checked his fall only after the down-drag of his weight began to close its holes.

A Nazi variation of the guided air missile was a torpedo for underwater work which went unerringly to its mark, drawn by the propeller sound of the victim ship from as far away as ten miles. This missile swam thirty feet below the water, at forty miles an hour, and left no wake. When directly under its target, it exploded.

All such revelations naturally raise the question: was Germany so far advanced in air, rocket, and missile research that, given a little more time, she might have won the war? Her war secrets, as now disclosed, would seem to indicate that possibility. And the Deputy Commanding General of Army Air Forces Intelligence, Air Technical Service Command [Donald L. Putt], has told the Society of Aeronautical Engineers within the past few months:

The Germans were preparing rocket surprises for the whole world in general and England in particular which would have, it is believed, changed the course of the war if the invasion had been postponed for so short a time as half a year.

[What Army Air Forces publication reported: "The V2 rocket, which bombed London, was just a toy compared to what the Germans had up their sleeve"???

The German news magazine *Der Spiegel* published a translated and heavily censored version of Charles Walker's 1946 article [Charles Walker 1946], and even that only came after an extraordinary five-year publishing delay [Der Spiegel 1951-06-05] Among the many details from Walker's article that were deleted by *Der Spiegel* were the precision guidance systems for the A-4 rocket, any mention of the A-9 or A-9/A-10 rockets, the fact that the Silbervogel was intended to be piloted, and the public declaration by U.S. Army Air Force experts that Germany was at least ten years more advanced than the United States in these areas. *Der Spiegel* also censored Donald Putt's quote, "The Germans were preparing rocket surprises for the whole world in general and England in particular which would have, it is believed, changed the course of the war if the invasion had been postponed for so short a time as half a year."]

Colonel George Bryant Woods. 1946. *The Aircraft Manufacturing Industry: Present and Future Prospects.* New York: White, Weld & Co. Frontispiece and p. 32.

[See pp. 5072–5073 for this extraordinary 1946 statement by a U.S. Army Air Forces intelligence expert on "Germany's Plans for the 'A-9' with Atomic Bomb."]

Senator Harry F. Byrd. 1948. Hitler's Experts Work for Us. *The American Magazine* (March) 145:24–25, 136–138.

[...] Who are these Germans—Zobel, Lippisch, Hermann, von Braun, Heinrich, Doblhoff, Goethert, Eckert, and the rest? Air Force authorities tell us that they are the scientists who put Germany years ahead of everyone in aeronautical science. They put some of their astounding new air weapons into combat before the war ended. Their jet and rocket fighters slashed through our bomber formations almost unmolested by our slower propeller-driven fighters. Their guided missiles, almost invisibly fast, were conceived to track down planes in flight and explode automatically when near them. Their jet V-1 and rocket V-2 did great damage in England and Europe; we had developed little defense against either the former or the latter. Almost ready was a V-2 of much greater range, for more widespread destruction. As the war ended, I personally saw the progress they had made on the super V-2 type, rocket-powered, which they thought might blast New York across 3,000 miles of Atlantic Ocean.

They started research on supersonics (speeds faster than that of sound) years before we did. Air Force officers concede that they were so far along that uncharted road that findings we captured made radical changes necessary in our supersonic plans, as applied to both planes and guided missiles.

"It will probably cost $100,000,000 to achieve practical supersonic flight" (with a piloted plane), wrote Lt. Gen. Nathan F. Twining, former Wright Field commander, in THE AMERICAN MAGAZINE for August, 1946. There is no estimate on what it would have cost without benefit of the earlier German research.

General Putt states: "Our Washington people say that in guided-missile development alone the Germans we've brought to American will save us 10 years and $750,000,000, and that seems reasonable to me. I'm sure that the total saving will amount to billions of dollars, but the actual figure must be anyone's guess today."

It may be said that German scientists, including those now working for us, were revolutionizing the entire character of air warfare. They were making nearly all the conventional air weapons of World War II obsolete. Jet and rocket propulsion is now virtually a requirement for all combat planes except the longest-range bombers. Guided missiles of fantastic speeds, altitudes, ranges, and destructive force—atomic or high-explosive—are in the making.

These German scientists are showing us how their tricks were done. They are helping us to catch up in our research the easy way. They are carrying on for us the research projects they were forced to interrupt in Germany. They are helping to ensure our aeronautical superiority. [...]

In Germany in the summer of 1945, Maj. Gen. Hugh J. Knerr, now Air Inspector, sent a memorandum to Lt. Gen. Carl A. Spaatz, who then commanded the AAF in Europe. "Occupation of German scientific and industrial establishments," he wrote, "has revealed the fact that we have been alarmingly backward in many fields of research."

General Putt, then a colonel, was in Germany leading the Air Force Intelligence teams which took over the research laboratories, experimental stations, and production plants. "I visited a great many of them," he said, "and talked with the German specialists who manned them. Their research progress in jet and rocket propulsion, aerodynamics, thermodynamics, supersonics, and other fields was clearly far ahead of anything of the kind we had done." [...]

The Air Force Intelligence teams harvested 1,200 tons of German scientific records, screened out the most important 150 tons, and shipped them to Wright Field for translation and evaluation. "But the records weren't enough," said General Putt. "The real need—and it's still greater today—was to put the Germans to work again at their research projects, but now for us. That's what started the procession of German specialists to America." [...]

Col. W. R. Clingerman, chief of the group which administers the Germans' affairs at Wright Field, explains, "They were paid the regular civil-service $6 per diem for detached service. From that they paid 25 to 35 cents for ordinary army mess, per meal, plus 50 to 75 cents a day for janitor or orderly service. They spent about a day's pay each week on packages of lard, coffee, cigarettes, dried eggs, candy, and such things, which they sent to their families in Germany. They also paid for all their clothes, laundry, tobacco, transportation, entertainment, magazines, books, and incidentals.

"Theoretically, they were paid salaries, but they never saw the money. [...] All of it went to their families or dependents, who weren't allowed to leave Germany. Most their families lived in an army housing area at Landshut, Bavaria, where they were guaranteed food, fuel, light, and some other things at fair prices." [Thus the scientists had to spend the "salaries" they were given to pay the U.S. military for keeping themselves and their families in custody.] [...]

When they first arrived they were hungry, and correspondingly meek. Once fed, their native German arrogance reasserted itself. Under the Nazis they had been pampered with special housing, rations, and privileges. Now there were desk-pounding complaints about their surveillance, contracts, housing, delays in getting mail—and even pay—possible loss of assets in Germany, and the security and welfare of families still there. [...]

They complained, and with truth, that they were given no constructive work. For months they wrote routine reports, or twiddled their thumbs, until their made-in-Germany records were translated and evaluated and they were interviewed, by Air Force and industrial engineers, to extract usable information about their past scientific and technical accomplishments. But in this their native German vanity proved valuable. [...]

It was succeeded by a formal contract, renewable yearly for a maximum of five years. [...] But in nearly all its provisions—as to duration, pay, hours, administration, patents, housing, subsistence, surveillance, mail, termination, return to Germany, and even burial—the U.S. Government is judge, jury, and jailer. [...]

"The Germans' salaries," said General Putt, "range from $2,200 to $8,000 per year, and average about $5,500. To establish them, we submitted standard applications, giving detailed qualifications, to Air Force civilian personnel authorities. In all cases salaries were set *one grade lower* than would be paid to Americans with the same qualifications. [...]

Among the first to arrive, in September, 1945, was Dr. Theodor Zobel, wind-tunnel expert of Germany biggest research institute, at Brunswick near Berlin. [...]

Evaluating Dr. Zobel's work, Wright Field's Dr. Wattendorf said, "It has saved us about five years of extremely expensive research time. In fact, five years would fairly measure the research savings of each of the top-flight German scientists working for us."

Also at Wright Field is Dr. Bernhard Goethert. He, too, specialized in high-speed airflow research, especially as applied to wing shapes. His findings influenced the design of the V-1 and the fastest German jet and rocket fighters. Their swept-back wings are believed by many aerodynamic authorities to be best for supersonic flight. [...]

The aerodynamic work on the devastating V-2 was done largely by Dr. Rudolf Hermann who, like Dr. von Braun, was at Peenemünde. He designed a 7,000-m.p.h. wind tunnel, for testing guided-missile models, and was supervising its construction in the Bavarian Alps when the war ended. He brought with him to Wright Field his own staff of 7 expert laboratory assistants, together with much unpublished data on his most important supersonic experiments. The Air Force has plans for his super-supersonic wind tunnel in the great air-research center which the Air Force wants to establish.

Meanwhile, Dr. Hermann is contributing his scientific talents to our guided-missile program. For the Nazis, he designed a 3,000-mile missile. For us, he might produce one with a range of 4,000 to 5,000 miles.

Even faster than the German jet fighters was the rocket-powered ME-163, which got into combat late in the war. Its designer was Dr. Alexander Lippisch, known for his glider experiments before the war. He did research work on supersonics and ballistics, notably on the V-2, and was a leading authority on the flying wing. He was one of the group of German specialists who were making preliminary plans for a “space base”—to be used for refueling rocket ships—which would revolve around the earth as a satellite at a distance of about 4,000 miles. That idea probably sounds fantastic, but the Air Force has listed it as a future project.

The Germans flew their first jet plane in 1939. We didn’t start developing ours until 1942. Fuels, combustion processes, and cooling play very important roles in jet engines. Dr. Ernst Eckert, a thermodynamicist, was in charge of such research at the Brunswick institute. Despite Germany’s lack of critical heat-resistant alloys, thought to be vital in jet turbines, Dr. Eckert produced substitutes which got their jet planes into combat. He is now working in the Wright Field power plant laboratory, continuing his thermodynamic research for the improvement of our jet engines, especially the supersimple ram-jet types.

During the war we were led to believe that our Norden bombsight was infinitely superior to all other bombsights, but the Germans are said to have had bombsights as good as ours in some respects, and superior in others. Joseph Shugt played an important part in their development. He is now experimenting with new bombsights in the Wright Field armament laboratory, where about 10 other German specialists are also working on research in ballistics, dynamics, and automatic instruments of various kinds.

Dr. Helmut Heinrich and Gerhard Aichinger, M.S., conducting research at Stuttgart, developed the “ribbon” type of parachute for very high speeds and altitudes. Even our propeller-driven planes had reached speeds so high that bailouts with our conventional chutes were often fatal. With their “ribbon” chutes, German pilots could bail out safely at greater speeds and higher altitudes. This chute also made it possible to recover the instrument-bearing sections of experimental guided missiles such as the V-2, something we had not done. Both Dr. Heinrich and Mr. Aichinger are now continuing their research for the Air Force, experimenting with rescue devices for extremely high speeds and altitudes.

The Germans were advanced also at the start of the war in the field of aero-medicine. They studied the physiological effects of oxygen-deficiency and low air pressures at very high altitudes, and the “blackout” results of the terrific accelerations encountered in very high speeds. In the latter research they were among the first to use a “human” centrifuge—which actually spins the flier’s body at high acceleration.

Much of this research was carried on at the Berlin Aero-Medical Institute by Dr. Otto Gauer. Now conducting further research in these fields at Wright Field’s aero-medical laboratory, Dr. Gauer is assisted by nearly a score of other German specialists, most of whom did similar research work at the Heidelberg Aero-Medical Institute. [...]

We have in our employ—or custody, if you prefer—German scientists and specialists whose work has been outstanding. They know every foot of that arduous research road, because they were the first to explore and travel it. In doing so they displayed great scientific imagination and technical competence. In my opinion, we are entitled to exploit these talents to our best possible advantage.

[Harry Byrd was a U.S. senator from Virginia 1933–1965. By 1948, he had already been in the Senate for 15 years, was a member of the Senate Armed Services Committee, and was a very well-known and powerful senator.

He wrote that after the war, he had personally seen rockets that were much more advanced than the V-2 and were ready or nearly ready by the end of the war. That agreed well with other sources quoted in this section. Byrd also wrote that at least some of the German scientists who had worked on those rockets were brought to the United States, where they were extensively interrogated and wrote reports. Where are all of those interrogation transcripts, reports, original documents, and inspection details on the rockets that Byrd saw in person? Can those be located and declassified?

Byrd’s article agreed with a number of other descriptions that German-speaking scientists were at least 10 years ahead of the United States in many fields, and that the transfer of German and Austrian innovators and innovations to the United States was worth many billions of 1940s dollars.

With regard to the general topic of producing revolutionary innovators and innovations, one should compare this U.S. senator’s description of:

- How these revolutionary innovators were treated in the German-speaking world vs. how the same innovators were treated in the United States.
- How much support was provided for developing revolutionary innovations in the German-speaking world, vs. how the United States was consciously spending as little money as possible just to transfer existing innovators and innovations from the German-speaking world to the United States.

As openly described by this high-ranking senator, from its national establishment in the 1940s, the U.S. research system was based on exploitation (e.g., “the total saving will amount to billions of dollars” vs. “Theoretically, they were paid salaries, but they never saw the money”), avoidance of challenging intellectual work (“These German scientists are showing us how their tricks were done. They are helping us to catch up in our research the easy way.”), and prejudice (“Once fed, their native German arrogance reasserted itself” and “their native German vanity proved valuable”). It would be difficult for a research system founded on such cornerstones to go on to produce as many new revolutionary innovators and new revolutionary innovations all of its own as a system that is more supportive of people and ideas. 75+ years later, it appears that has indeed proved to be the case (Section 11.3).]

Nazis Were Working On 100-Ton Rocket. ***The Courier-Mail*** **(Brisbane, Australia). 5 December 1946 p. 1.** [**https://trove.nla.gov.au/newspaper/article/49363386**]

NEW YORK, December 4.—When the war ended the Nazis were building a 100-ton rocket with which to strike at the United States.

This has been revealed by the brilliant German scientist, Wernher von Braun, who invented the V2 rocket.

Von Braun is now in the United States working with American experts on rocket experiments.

The super-rocket, he said, was on the drawing-board when Germany was over-run. It would have carried an explosive charge of six tons, and would have been capable of travelling thousands of miles.

He claimed that the V2 rocket failed in only about 5 per cent of its tests in Germany.

Von Braun and his associates from Germany are being kept at work under the utmost secrecy by the Army as they help to train American ordnance men, industrialists, and scientists from leading American universities in the secrets of rocket bombs.

U.S. Gain

An estimate that German and Austrian scientists had saved the United States more than £235 million in basic research in rockets alone was disclosed by the War Department in announcing that 730 additional experts were to be brought to the United States.

Former enemy brain-power, the department said, had advanced American research in several fields by from two to 10 years.

Already 270 former enemy scientists are at work in the United States. They include the former chief designer for the Messerschmitt aircraft works and the technical director of the Nazis' Peenemunde rocket proving ground. They came to the United States voluntarily.

The scientists are being paid on contract, the maximum being £975 annually, plus 37/ daily expense allowance. This is considerably less than the salaries paid to American civil service workers doing comparable work.

The work of the foreign scientists covers the fields of electronics, supersonics, guided missiles, jet propulsion, and fuels.

["100-ton rocket" was a name sometimes used by the Peenemünde engineers for the A-9/A-10.

Usually the expected payload of the A-9/A-10 is given as 1 ton. That could be stretched to 2 tons without much trouble. But why is the payload given here as 6 tons? Was this a different version of the A-9/A-10, or a different rocket entirely?

Why did the payload need to be 6 tons? Did that include two pilots, guidance systems, bomb, etc.? Was it an attempt to fit 6 tons of conventional explosive on the rocket to better justify the expense? Was it a 6-ton fission bomb or hydrogen bomb?]

Nazi Scientists Work On U.S. Rocket Experiment. *Newcastle Morning Herald and Miners' Advocate* (New South Wales, Australia). 5 December 1946 p. 3. [https://trove.nla.gov.au/newspaper/article/133178482]

NEW YORK, Dec. 4.—Before the war ended the Nazis were building a 100-ton rocket to strike the United States. This was revealed by the brilliant German scientist Wernher von Braun, who invented the V2 rocket, and who is now in the United States.

Von Braun is at present working with American experts on rocket experiments.

He said the Nazis' super-rocket was on the drawing board when Germany was overrun. It would have carried an explosive charge of six tons and be capable of travelling thousands of miles.

Von Braun claimed the V2 failed in only about five per cent of its tests in Germany.

Von Braun and his associates from Germany are being kept at work under the utmost secrecy by the army as they help to train American ordnance men, and industrialists and scientists from leading American Universities in the secrets of rocket bombs.

Saved U.S. Millions

A statement issued by the War Department in Washington said it was estimated that German and Austrian scientists had saved the United States more than 750 million dollars (£A234 1/2 millions) in basic research in rockets alone.

The department announced that about 730 additional experts would be brought to the United States.

The statement said that former enemy brainpower had advanced American research in several fields two to ten years. The number of experts put to work since September 1945 had grown to 270, and the total would be increased to about 1000 as soon as transportation arrangements were completed.

The scientists and technicians include the former Chief Designer for the Messerschmitt Aircraft Works and the Technical Director of the Nazis' Peenemunde rocket-proving ground. They came to the United States voluntarily.

Nazis Planned Rocket to Hit U.S. *New York Times.* 4 December 1946.

Wernher von Braun, 34-year-old German scientist who invented the deadly V-2 supersonic rocket, revealed today that before the war ended the Nazis were building a 100-ton rocket to strike at the United States.

Von Braun told reporters that the 100-ton rocket was on the drawing board when the Allies overran Europe. He said it would have carried a "pay-load" of six tons and would have traveled thousands of miles to strike the United States.

Frank H. Winter. George Sutton, the (Other) Father of American Rocketry. *Smithsonian*, 16 November 2020. https://www.smithsonianmag.com/air-space-magazine/george-sutton-other-father-american-rocketry-180976306/

Born Georg Paul Erich Schulhof in Vienna, Sutton was compelled to leave Austria for the United States in June 1938, just three months after the Anschluss. Traveling alone, the 17-year-old was listed as a student on ship passenger lists. After settling in Los Angeles with the family of his uncle, he later anglicized his name to George Paul Sutton and applied to become a U.S. citizen. Although he originally intended to follow family tradition and become a medical doctor, his interests soon took a different direction. After obtaining an associate of arts degree in Mechanical Engineering from Los Angeles City College in 1940, he went on to earn a master's degree in the same field from Caltech in 1943.

Following his graduation that spring, he joined the Aerojet Engineering Corporation (now Aerojet Rocketdyne), which had just opened its doors in Pasadena a year earlier as the second liquid-propellant rocket company in the United States. During this formative period of the American rocket industry, the main focus was not missiles but JATOs—Jet-Assisted-Take-Off units—to shorten the take-off distances for heavily loaded aircraft.

Sutton's first jobs at Aerojet involved rocketry, however, under the guidance of Theodore von Kármán, the company's first president. Sutton became a test engineer on a nitric acid/aniline thrust chamber, then worked on Aerojet's unique, double-chambered rocket engine intended to power the ill-fated Northrop XP-79 Flying-Wing interceptor, which was canceled after one fatal test flight.

He stayed at Aerojet until 1946, then joined North American Aviation as a research engineer to continue his work in rocketry. The U.S. Army Air Forces had recently invited aviation companies to bid on preliminary designs for guided missiles, and NAA's proposal for a 100- to 500-mile range missile called Navaho (for North American Vehicle [using] Alcohol [and] Hydrogen Peroxide and [Liquid] Oxygen) was accepted.

Although North American had no experience in rocketry, it did have highly competent engineers and planners, and the company established a new Aerophysics Laboratory to take on the challenge. Along with his experience working with liquid-fuel rocket motors at Aerojet, Sutton's native German was especially prized, as the Navaho team intensely studied blueprints and hardware from captured V-2 rockets. Sutton was one of the first U.S. rocket engineers sent to Fort Bliss, Texas, to interrogate Wernher von Braun, the former technical director of the V-2 program who had surrendered to the Americans at the close of the war. Besides interviewing other Germans on von Braun's team, he was among the engineers who completely dismantled a V-2 engine or two to see how they worked and how they were made. These engines, as one later historian of Rocketdyne put it, "were torn down and dissected in fine detail."

Under Phase 2 of the Navaho project, NAA began constructing replicas of the V-2 engine under Sutton's supervision, one of which is in the collection of the National Air and Space Museum. These weren't precise copies—the Americans used English rather than metric measurements, along with American screw threads, O-rings and other parts. The captured V-2 engines had come to the United States minus their turbopumps, so American-manufactured aluminum pumps were substituted for the original German steel pumps.

George P. Sutton. 2006. *History of Liquid Propellant Rocket Engines.* Reston, Virginia: American Institute of Aeronautics and Astronautics.

[p. 269:] It is an ironic twist of history that Goddard's pioneering work in LPREs [Liquid Propellant Rocket Engines] and sounding rocket vehicles had relatively little impact on U.S. LPRE development. The large U.S. LPREs, which were developed later by General Electric, Rocketdyne, and Aerojet, were designed and produced without the benefit of the work done by Goddard. [...] At that time (1947–1951) my fellow designers and I had not even heard of Goddard or any of his know-how[....] Instead, Rocketdyne received a lot of help and data from the Germans and their V-2 LPRE information, which was very useful.

[pp. 752–753:] In January 1945, when it was obvious that Germany was losing the war, the personnel at Peenemünde were ordered to evacuate the facility, and Wernher von Braun and his team left the facility, but took many documents and drawings with them. The majority of the key technical personnel surrendered to the American military, were transported to the United States, and eventually joined NASA, where they worked on launching U.S. satellites and on the Saturn Apollo project. During the 1946 [to] 1971 period, the author had repeated meetings with von Braun and about 15 of the Germans who came with him from Peenemünde. These interchanges were in connection with the Rocketdyne development of the large LPREs for the NASA Saturn/Apollo SLVs [Space Launch Vehicles], which were then designed by this team. A lot of information about German LPRE efforts came from this elite German team, and the data were very useful in the U.S. LPRE efforts. Several members of the former Peenemünde team joined various U.S. aerospace companies. For example, Walter Riedel, Dieter Huzel, and Kurt Rothe joined Rocketdyne; Rudi Beichel went to Aerojet[3]; Krafft Ehricke went to Convair[4]; and Walter Dornberger and a few others went to Bell Aircraft.[5] Other German rocket experts went to the Soviet Union, France, and Britain.

It is worth repeating that the V-2 LPRE was an outstanding historic achievement. Its thrust was ten times larger than any other engine at or before that time. The engine incorporated novel features that were copied, adapted, or modified by many subsequent large rocket engines. All the other nations in the LPRE business studied the V-2 engine and two (Soviet Union and the United States) built copies to learn the fabrication process.

[pp. 406–413:] Rocketdyne developed more large LPREs than any other company (except for USSR's Energomash). The first effort was to *copy, build, and flow test three American copies of the German V-2 rocket engine.* Your author was responsible for the effort of copying the thrust chamber of the V-2. [...]

The first indigenous large engine development effort was a pump-fed LPRE of 75,000 lb thrust, which soon became known as the engine for the Army's Redstone ballistic missile. The missile was built by Chrysler, but some of the vehicle's engineering was done by the Germans, formerly of Peenemünde under the leadership of Wernher von Braun.[6] The Rocketdyne-developed Redstone engine is shown in [p. 5500....] Some people consider it to be an upgraded V-2 engine because it used the same propellants (liquid oxygen and 75% ethyl alcohol) and had some similar features.

---

[3] Other German-speaking experts such as Karl Klager also went to Aerojet, and Aerojet was founded and run by Theodore von Kármán and Fritz Zwicky.

[4] Other German-speaking experts such as Hans Rudolf Friedrich and Walter Schwidetzky also went to Convair.

[5] Other German-speaking experts such as Heinz E. Mueller also went to Bell.
A number of other German-speaking experts such as Konrad Dannenberg, Hans Hueter, and Hans Lindenberg (died 1946) were also important for rocket engine design in the United States.

[6] See pp. 5354, 5502.

Like the V-2 engine, it had a heavy steel sheet, double-walled regenerative cooling jacket with supplementary film cooling, the turbopump had an aluminum turbine between the aluminum fuel and the oxidizer pumps, and jet vanes were used for thrust vector control during powered flight.

[...] The Redstone engine thrust and chamber pressure were higher, namely, 78,000 lpf vs 56,000 lbf and 317 vs 220 psia. [...]

The first static test of the complete Redstone engine took place in late 1950, and the first flight was in August 1953. It was part of the first U.S. ballistic missile to become operational, and the missiles were also deployed overseas in June 1958. This engine propelled a Redstone missile on 31 July 1958 at Johnston Island in the Pacific; it was carrying a live nuclear warhead to its first high-altitude detonation (at altitude of 47.7 miles). This engine also launched the first U.S. satellite (Explorer on 31 January 1958). [...] The modified Redstone missile also launched two U.S. astronauts in their Mercury capsule on their first suborbital space flights in 1961.

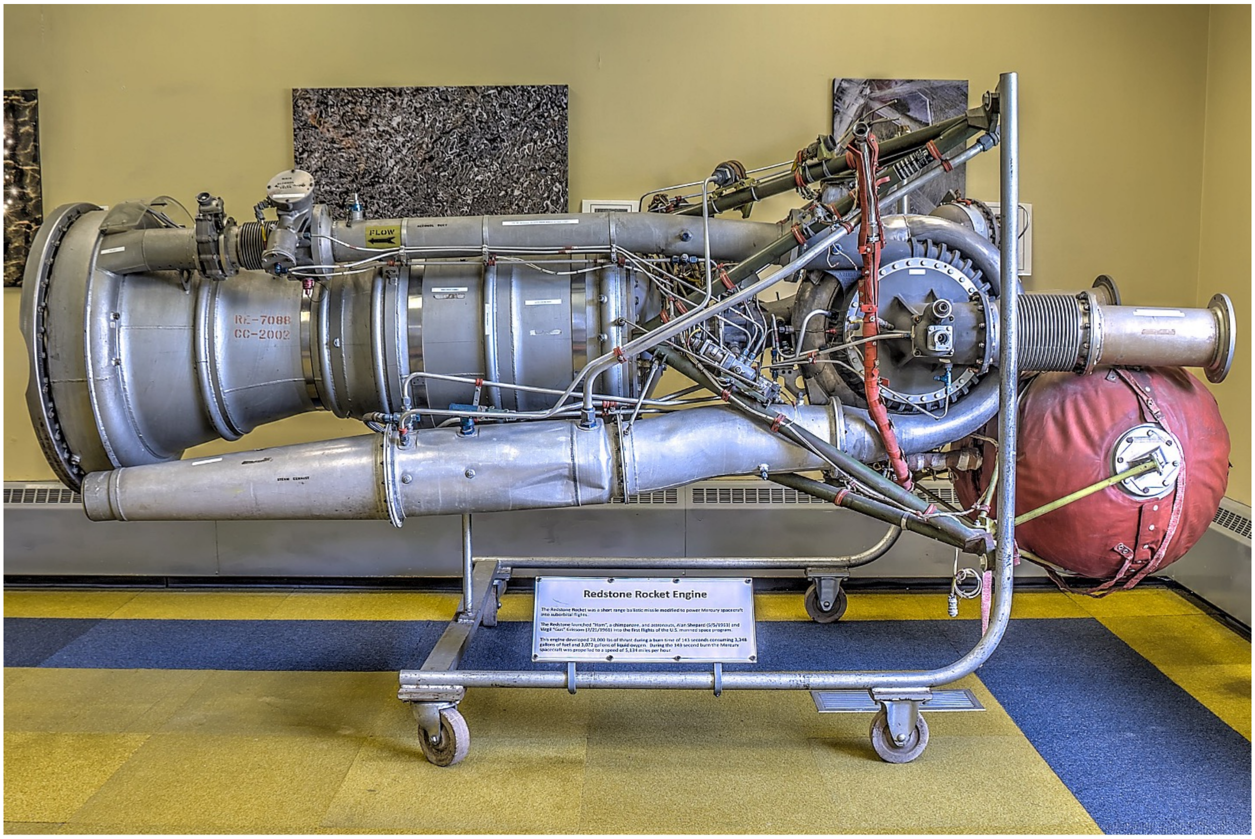

Figure E.143: The Redstone rocket engine (first flown in 1953) was directly derived from the earlier A-4 (V-2) engine and was designed by German-speaking experts including Georg Schulhof/George Sutton, Wernher von Braun, Konrad Dannenberg, Hans Hueter, Dieter Huzel, Hans Lindenberg (propellant injectors, before his death), Walter Riedel, Kurt Rothe, and others. German experts working independently in other countries after the war also produced remarkably similar rocket engine designs, demonstrating that they were using the same German design principles and likely even the same advanced wartime engine designs; see for example pp. 1880, 1884–1885. For wartime production of engines with advanced propellant injectors, see pp. 5284–5285. For another example of North American Aviation (home of Rocketdyne) using German engineers, German documents, German information, and German hardware, see p. 1768.

THE RECORD

August, 1953—Army's first successful firing of large ballistic missile, the Redstone, on which Chrysler is prime contractor. There have been 30 consecutive successful firings of the Redstone since.

May, 1957—first successful firing of an intermediate-range ballistic missile—Jupiter.

January, 1958—first free-world satellite, Explorer I, successfully launched at first attempt and still orbiting. Powered by the Jupiter 'C'.

March, 1959—first free-world solar satellite, Pioneer IV, first U. S. payload projected to permanent escape from the earth, powered by Juno II.

May, 1959—first successful space travel and safe return, carrying the famous monkeys Able and Baker, Jupiter launched.

Chrysler is also working on Project Mercury, America's program to carry man into space and back.

Chrysler Corporation builds Redstone and Jupiter Missiles on a production line basis

Cape Canaveral, Jan. 1958—U. S. Army's Jupiter 'C', sends the free world's first successful satellite Explorer I, into orbit.

What does missile making have to do with better automobiles?

Electronic engineering, the same engineering that enabled Chrysler to make America's most successful missiles as prime contractor to the U. S. Army, ends the months of production once needed to work the bugs out of new model automobiles. Now the first car off the assembly line at Chrysler is as perfect as the ones which roll off five months later.

Briefly, giant electronic computers predict performance before the car is built. They make computations in a few weeks that would take an engineering staff years of full-time work to figure out. As a result, we know just where to locate the engine mounts, just what spots to weld, and what gauges of metals to use. Electronic engineering has given us a better way to build better automobiles.

Figure E.145: The Chrysler automotive company worked closely with German-speaking creators to mass-produce the Redstone/Jupiter rockets and the first stage of the Saturn I/IB [*Life*, 5 October 1959, p. 30]. Chrysler produced no rockets before then, produced no other rockets during that time, and has never produced rockets since then. The rocket designs and details came from the German creators. See also pp. 5354, 5499.

Military Intelligence Division W.D.G.S., Military Attaché Report Czechoslovakia. Subject: Russian Demand for German Scientific Secrets. I.G. No. 0404.0700. Prague. Report No. R-32. 20 September 1945. [NARA RG 319, Entry NM3-85M, Box 19, Folder 925253]

Source and degree of reliability:
Czech General Staff Liaison Officer — A-3
Czech Counter Intelligence Officer — A-3

1. Cables No. 18, of 15 September 1945, 2nd subject, and No. 20, of 18 September 1945, are hereby confirmed.

2. A great many American technical intelligence teams have arrived in PRAHA from time to time since the Liberation on various missions, some of them to interview Czech scientists or German scientists living in Czechoslovakia, in regard to the research and development of German secret weapons. It was natural to assume that the Russians would have similar interests.

3. The following has been learned from a Czech Counter Intelligence Officer: When Czechoslovakia was liberated, all secrets pertaining to weapons, discoveries, research and experiments regarding new weapons or new agents of warfare were declared State Secrets, details of which were not to be be made available to anyone outside the Czechoslovak Government.

However, a Russian Technical Mission very soon appeared in PRAHA demanding details of a new German rocket in the experimental stage, referred to variously as V-3 and VA-4, experiments on which had been undertaken in the Protectorate. General BOCEK issued orders to show this mission "something that looked like something but which meant nothing".

Early in June a second Mission, more heavily backed by the Russian authorities, arrived, and General BOCEK under pressure directed that some parts of the rocket be given it, but since the manufacture was on the "mosaic" basis, this was less important.

A third Technical Mission arrive direct from MOSCOW in July, heavily backed up by the Russian Embassy and the Russian Military Mission, and General BOCEK was forced to furnish more parts and to give this Mission access to certain plans and drawings and to allow it to interview some German scientists who were in Czechoslovakia protective custody; however, the Czechs succeeded in withholding the main secrets.

Shortly after this, an American Technical Intelligence Team arrived in PRAHA on a similar mission; among other things they wanted to interview a Dr. H. FRANK, German scientist in Czechoslovak custody, who was held at TEREZIENSTADT. The Czechs were apparently very willing to produce him, but when the time came, it was found that he was no longer there, having been spirited away to PANKRAC Prison in PRAHA. I then personally made representations to the General Staff on the basis that Czechoslovakia and the United States were allied in the war against Japan, and more or less peremptorily demanded full cooperation, which was then given, and the Mission interviewed Dr. FRANK.

Note by M/A: I have since accidentally learned that much information was withheld from our Mission which left PRAHA with the conviction that little could be learned here.

After the departure of the American Technical Intelligence Team the Russians showed great indignation and put pressure to bear on General BOCEK who ordered the court-martial of those Czech officers who had assisted the American team. After considerable noise the thing died down, and General BOCEK passed out the word that nothing would be done, but that Czech officers must be extremely careful in their dealings with the Americans, due to the Russian attitude.

A fourth and final Russian Technical Mission arrived from MOSCOW on 31 August; this mission obviously had the highest backing and was able to put maximum pressure on the Czechs, with the result that General BOCEK issued orders over his signature, which my informant has personally seen, to the effect that anything and everything was to be given the Russian Mission, including parts and plans, and that they were to have free access to all scientists.

4. The Russian Scientific Mission has made offers to both German and Czech scientists of an outright payment of 10 million Czech Crowns ($100,000.00), a fine house in MOSCOW, special food and automobiles if they were willing to go there and work for the Russians; one scientist has disappeared with his wife during the night, taking along his personal belongings which were seen being loaded on a Russian Army truck. A member of this Mission has twice offered my source 10 million Czech Crowns if he would "work with me." Source feels that if German secrets are given to the Russians, they should be given to us as well, and is willing to make any scientist available for interview by American technical intelligence representatives.

5. It was stated by my General Staff source that in the meeting of Foreign Ministers in LONDON, Russia, China and France made unsuccessful demands on the United States and Great Britain for the secrets of the atomic bomb; the following day one battalion of Russian Infantry and certain technical troops occupied the uranium mine and factory in JACHIMOV (St. JOACHIMSTHAL), the only place in Central Europe where uranium is produced, this in spite of the fact that occupation of this area was not provided for in the Russo-Czech agreement. The Russians immediately demanded that the Czechs treble their output. The British Ministry Attache a few days later received an anonymous note giving no details but stating that the Russians had occupied the JACHIMOV mine.

Comment by M/A: It is obvious that the Russians are anxious to secure all possible details of German experiments on secret weapons. Why they should occupy an insignificant uranium mine like the one at JACHIMOV when they have great uranium deposits in their own country is not known, except that it may be to forestall any independent Czech research along these lines.

It is felt that the Counter Intelligence Officer's willingness to cooperate with this office may be inspired by certain high Czech officers who fear the one-sided cooperation with the Red Army and favor a better balance. Personally I am inclined to think that General BOCEK himself may be behind this move, as he has always been extremely frank and friendly with me, and I have known him for a long time.

AAGE WOLDIKE

Military Attaché

[See document photos on pp. 5506–5507.

To aid in visualizing the locations mentioned in this document and the following several documents, see p. 2098.

A new German rocket had reached the experimental stage in Czechoslovakia during the war, and was so advanced that the postwar Czechoslovakian government wanted to keep the rocket for itself instead of turning it over to the Soviets. It may or may not have been the same as V-3 or V-4 rockets mentioned by other sources. Writing VA-4 instead of V-4 might simply be a typo, or it might indicate that the new rocket was somehow related to the previous A-4 or V-2 rocket.

This report demonstrates how deeply indebted postwar Soviet programs were to German scientists, technologies, prototypes, and supplies. It also illustrates how little U.S. and U.K. inspectors were allowed to learn about wartime German work that occurred in areas that were subsequently occupied by the Soviet Union.

For more information on Helmar Frank, see pp. 1050–1072, 2756–2757, 3983, 5513, and 5549.]

Military Attache Report CZECHOSLOVAKIA
(Country reported on)

Subject Scientists Experimenting on Secret Weapons (Brief descriptive title) I. G. No. 0403.0700

From M. A. PRAHA Report No. R-42 Date 2 October 1945

Source and degree of reliability:

Czechoslovak Counterintelligence Offi[illegible]r - A-3 SD 2959

Summary.—Here enter careful summary of report, containing substance succinctly stated; include important facts, names, places, dates, etc.

1. In accordance with directions contained in War Department Cable No. 68418, of 24 September 1945, the following list of scientists, Czech and German, with their specialties and present status, is submitted.

2. a. The HÜTTIG GROUP is probably the most important. Professor HÜTTIG was the head of the Czechoslovak Radiological Institute during the Occupation; this is the only group which worked on practical application in warfare of the splitting of the atom. They are not known to have conducted any practical experiments, but they worked on the theory under the supervision of a German, Professor Dr. BRAUN, who has just been located in Czechoslovakia and is expected in PRAHA today's date, where he will be available to the Czech authorities. In addition to the calculations for the atomic bomb, Professor HÜTTIG perfected a radar-disturbing paint for U-boats, a sample of which has been promised this office. Within the last few days a complete Cyclotron, which I understand is an apparatus used in the splitting of the atom, was found in the VOLLMAN Factory at CELAKOVICE, Central Bohemia, and has been moved to PRAHA.

~~DECLASSIFIED - DOD Directive No 5200.9, 27 September 195~~ 4/14 59

The HÜTTIG Group consists of:

Professor HÜTTIG, German, free but available to Czech authorities.

His principal assistant, Dr. KAFKA, German, free but available to Czech authorities.

Professor Dr. ZACEK, Czech, free but available to Czech authorities.

Professor BIEHONEK, Czech, free but available to Czech authorities. The two latter are subject to arrest at any time.

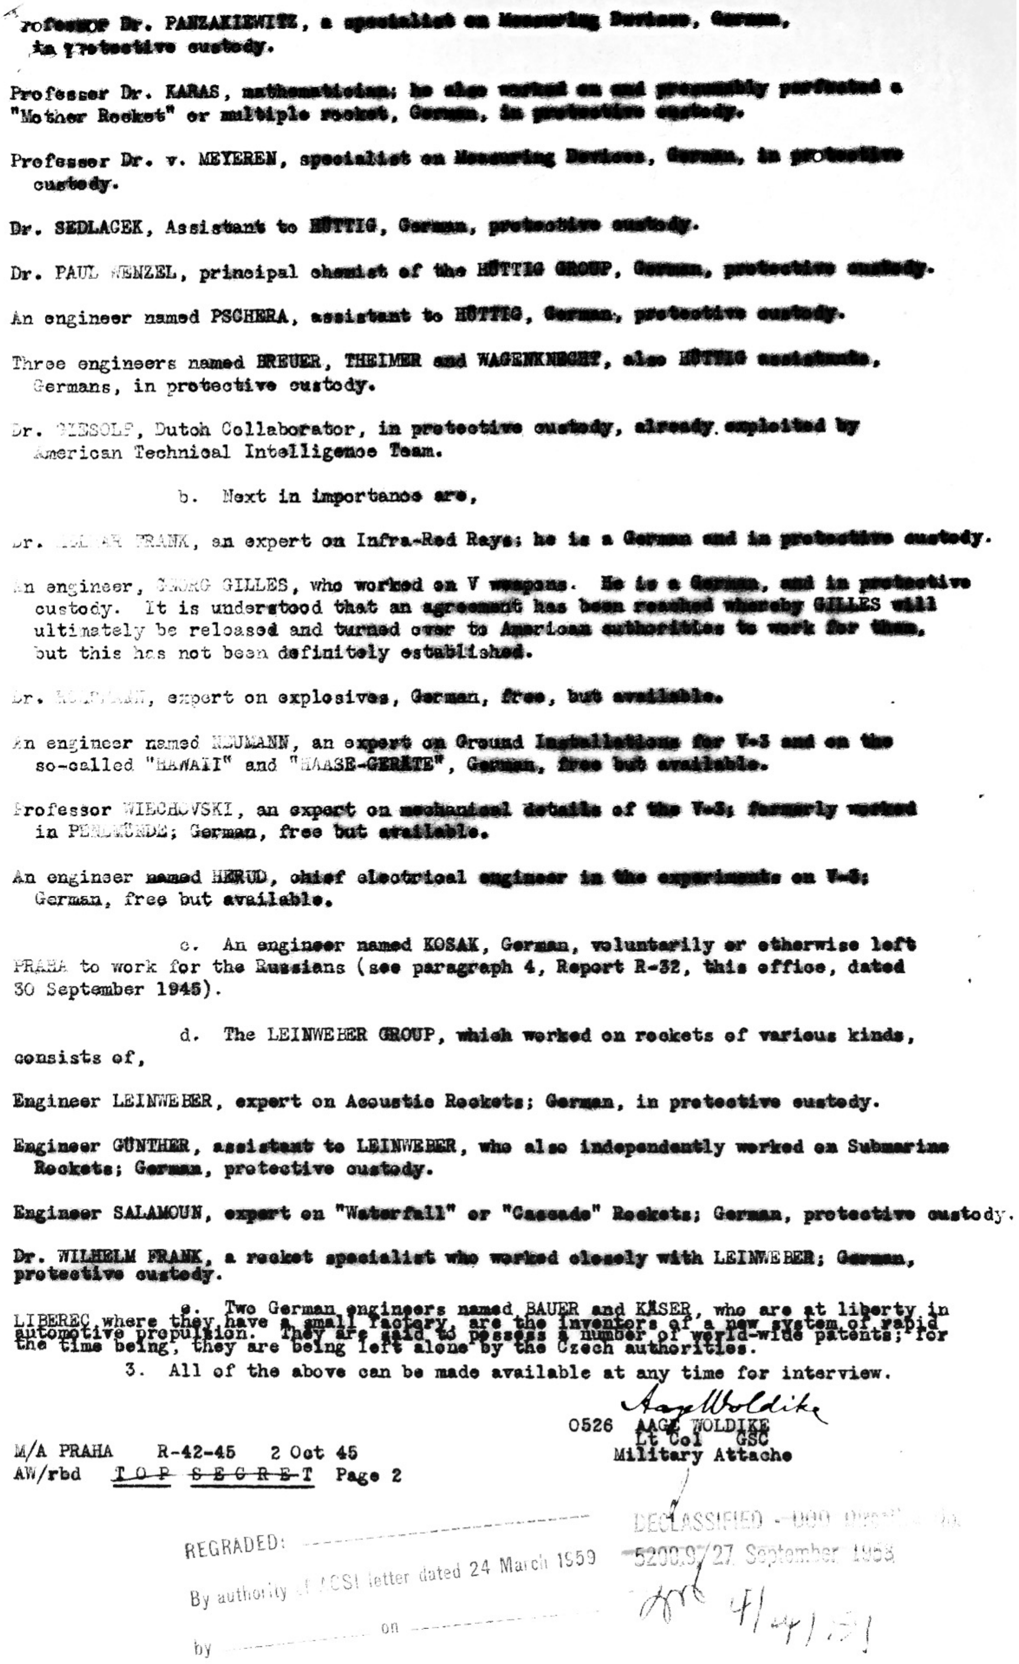
DECLASSIFIED
Authority NND 758[illegible]



Professor Dr. PANZAKIEWITZ, a specialist on Measuring Devices, German, in protective custody.

Professer Dr. KARAS, mathematician; he also worked on and presumably perfected a "Mother Rocket" or multiple rocket, German, in protective custody.

Professer Dr. v. MEYEREN, specialist on Measuring Devices, German, in protective custody.

Dr. SEDLACEK, Assistant to HÜTTIG, German, protective custody.

Dr. PAUL WENZEL, principal chemist of the HÜTTIG GROUP, German, protective custody.

An engineer named PSCHERA, assistant to HÜTTIG, German, protective custody.

Three engineers named BREUER, THEIMER and WAGENKNECHT, also HÜTTIG assistants, Germans, in protective custody.

Dr. GIESOLF, Dutch Collaborator, in protective custody, already exploited by American Technical Intelligence Team.

b. Next in importance are,

Dr. [illegible] FRANK, an expert on Infra-Red Rays; he is a German and in protective custody.

An engineer, GEORG GILLES, who worked on V weapons. He is a German, and in protective custody. It is understood that an agreement has been reached whereby GILLES will ultimately be released and turned over to American authorities to work for them, but this has not been definitely established.

Dr. [illegible], expert on explosives, German, free, but available.

An engineer named NEUMANN, an expert on Ground Installations for V-3 and on the so-called "HAWAII" and "HAASE-GERÄTE", German, free but available.

Professor WIECHOVSKI, an expert on mechanical details of the V-3; formerly worked in PEENEMÜNDE; German, free but available.

An engineer named HERUD, chief electrical engineer in the experiments on V-3; German, free but available.

c. An engineer named KOSAK, German, voluntarily or otherwise left PRAHA to work for the Russians (see paragraph 4, Report R-32, this office, dated 30 September 1945).

d. The LEINWEBER GROUP, which worked on rockets of various kinds, consists of,

Engineer LEINWEBER, expert on Acoustic Rockets; German, in protective custody.

Engineer GÜNTHER, assistant to LEINWEBER, who also independently worked on Submarine Rockets; German, protective custody.

Engineer SALAMOUN, expert on "Waterfall" or "Cascade" Rockets; German, protective custody.

Dr. WILHELM FRANK, a rocket specialist who worked closely with LEINWEBER; German, protective custody.

e. Two German engineers named BAUER and KÄSER, who are at liberty in LIBEREC where they have a small factory, are the inventors of a new system of rapid automotive propulsion. They are said to possess a number of world-wide patents; for the time being, they are being left alone by the Czech authorities.

3. All of the above can be made available at any time for interview.

Engineer SALAMOUN, expert on “Waterfall” or “Cascade” [Wasserfall surface-to-air] Rockets; German, protective custody.

e. Two German engineers named BAUER and KÄSER, who are at liberty in LIBEREC where they have a small factory, are the inventors of a new system of rapid automotive propulsion. They are said to possess a number of world-widepatents; for the time being, they are being left alone by the Czech authorities.

3. All of the above can be made available at any time for interview.

AAGE WOLDIKE
Lt. Col GSC
Military Attaché

[This report stated that the Hüttig group was working on theoretical calculations for the atomic bomb, under the supervision of a "Professor Dr. Braun" who may have helped to coordinate their work with a larger German nuclear weapons program.

The Alsos Mission found reports from some members of the Hüttig group in the files of Walther Gerlach, the German Plenipotentiary for Nuclear Physics during the final stages of the war.

Note that the report mentioned a cyclotron that was produced in wartime Czechoslovakia; this cyclotron is also mentioned in subsequent documents.

Some of the engineers who worked on the "V-3" rocket are specifically identified here.

For more information on Helmar Frank, see pp. 1050–1072, 2756–2757, 3983, 5503, and 5549.

For more information on some of the other named scientists, see
https://dspace.cuni.cz/bitstream/handle/20.500.11956/47183/140006538.pdf.]

The Puzzle of Podmokly. *Time.* 12 November 1945.

Had the atomic armaments race begun? In Moscow a writer for The New Times declared that reactionary forces in the U.S. were bent on "blackmailing humanity" by trying to keep the atomic bomb a U.S. property.

From western Czechoslovakia, where the Elbe river bursts through the Sudeten mountains into the flat meadow lands bordering Germany, came a different story.

Nestled in the mountains six miles from Podmokly was a vast underground factory, the Weser Works. In the first three months of liberation the Weser Works were quiet, deserted. Now they hummed with hidden activity. Czech and Russian security police kept close watch on the difficult mountain approaches.

The underground factory was a product of the war. When the Germans came to Podmokly (which they called Bodenbach) they seized the Krizik Works, Czechoslovakia's largest producer of copper wire, the area was rich in coal and hydroelectric power, and had excellent communication facilities. Later they imported French, Belgian and Russian laborers, and set them to work expanding the Krizik plants. Laboratories were built, buildings enlarged, new units erected. One of the new units was put underground, and was supersecret. It was known simply as "the Weser."

The Losing Race.

In time the first secret of the Weser became apparent. Its parent plant was producing V-weapons. But it also manufactured cyclotrons for atomic experimentation. As the Allies bombed German laboratories, the Weser shipped new cyclotrons to secret destinations in the Reich where Hitler's scientists were running a losing race with history. At least three cyclotrons were shipped in the last year and a half of war.

The retreating Germans left the Weser grounds littered with the fuselages, fins and working parts of V-bombs. In iron safes were plans for Vergeltungswaffe-4, said to be a giant, radio-controlled rocket capable of being fired from Prague to the Americas. The Germans also left parts of cyclotrons and other equipment for research in nuclear physics.

For a time the Russians showed no particular interest in the underground factory. Strangers wandered in & out at will. But the explosions over Hiroshima and Nagasaki brought a quick change. The security police moved in, and Germans who had worked in the factory were rounded up, put back to work. Former officials of the Krizik Works were kept out. In northern Bohemia the Russians took over the Jachymov mine, famed for its uranium deposits.

If the Weser's cyclotrons were what interested the Russians, Moscow was still in the experimental stage of atomic development. The U.S. had entered the production stage in 1943.

[The Weser and Krizik Works near Podmokly was a very large German weapons research, development, and production complex during the war. It was reportedly involved in nuclear weapons work, advanced rockets, and other revolutionary innovations.

U.S. intelligence reports explained that the Bohemian V-4 rocket had both an increased range and an improved payload compared to the much better known A-4 (V-2) rocket (p. 5544), and that it was actually "completed," not just a paper design (p. 5516).

Why did Weser/Krizik produce at least three cyclotrons (or maybe more) during the war?

Can all of the records from the Weser/Krizik complex be located in Russia and released?]

V. L. Rychly. Report No. 2655: Report on Visit to Czechoslovakia. 11 February 1946. [NARA RG 38, Entry 98C, Box 9, Folder TSC # 2601–2700]

A. Between 3 January and 22 January, arrangements were made with the Czech'k General Staff to visit a number of plants that had been working for the German Navy during the war. Contact was made with this Staff through the British and U.S. Military Attachés who introduced me to Gen. BOCEK. The Czech authorities granted the permission but informed me that I would have to be escorted throughout by the Czech Secret Police (O.B.Z.). The plants visited were the following:

1. C.S.R. ZBROJOVKA at BRNO (Moravia) [formerly Waffenwerke-Brünn]. This firm has in all some eight plants in a radius of 70 Klms of BRNO. [...] Also removed [by the Russian Tech Control Commission] were all documents, drawings and a number of leading technicians.

2. PRVNI PRNENSKA STROJIRNA, BRNO (Moravia). [...] From this plant all documents were removed by the Russians, but no further work was carried out under their supervision.

3. BATA, ZLIN (Moravia). [...] Rubber for experimental [anti-sonar and/or anti-radar stealth] coverings of U-boat hulls. [...]

4. ZIKMUND-CHEMA at LUTIN (Moravia). [...] All documents and valuable machinery were removed by the Russians who, however, evacuated none of the technicians and scientists.

5. STEIN and SPOL at BRNO (Moravia). [...] Everything of interest was removed by the Russians.

6. SCHMIDDING at PODMOKLY (Bohemia). [...] By October 1945 the Russians stopped production, removed the completed torpedoes and other weapons, duplicates of all documents and number of German engineers to Russia.

7. WESERWERKE at DECIN (Teschen) (Bohemia). A lot of inaccurate reports have been circulated about the work carried on in the vast underground workshops of this plant. It has been reported that cyclotrons were manufactured and that in laboratories work was being carried out on atom smashing in conjunction with uranium isotope 235.

In actual fact the following work was carried out: production of V-1 and V-2. 55mm rockets. Schlange. Wespe. 30mm pneumatic cannon. Remote control rockets.

This plant was very strictly guarded until 1 December 1945, and it is thought that German technicians were still employed there up to that date. The plant has now been evacuated.

8. A.E.G. at BEDRICHOV (Bohemia). Manufactured F.B. Zielsuchgeraet. Pfau. Amsel. Ida 105 mine, accoustic, induction and reacting to change in water pressure. V-1 and V-2 fuses. The completed V-4. Lichtspiegelanlage.

The German scientists Pfister and Bakes, with whom I had the opportunity to speak, and some 22 other German scientists are still working on the development of the above under Czech supervision for the Russians. The program on which this firm is still engaged is much more extensive than that listed above. Pfister tried to pass me a copy of the complete program of work, but this was seized from my hand by one of the O.B.Z. officials present.

The O.B.Z. official promised that I should obtain a copy of this program in Prague. On arrival there General Bocek gave orders for it to be surrendered to me, but this got to the ears of Colonel Reicin, the right hand man of General Svoboda, who forbade the authorities to let me have a copy.

Both Pfister and Bakes seemed most keen to be of assistance to us.

9. VOLMAN at CELAKOVICE (Bohemia). Manufactured 3 cyclotrons that were removed to Russia. No work was proceeding in the factory.

10. CESKO-MORAVSKA. KOLBEN-DANEK at SLANY and PRAGUE (Bohemia). [...] This plant was bombed out entirely and as far as is known the Russians removed nothing. [...]

11. HAVEILKA PRAGUE (Bohemia). Manufactured bridge superstructures and conning towers for U-boat types XXI, XXIII, and XXVI W. [...]

The chief engineer of the firm carried out a tirade against the management of the works in my presence and was there and then removed by the O.B.Z.

12. ASKANIA PRAGUE (Bohemia). Works in Prague were bombed out. No permission was granted to see the other Askania works which were reported to me by a friendly major of the Czech General Staff as being inaccessible to Czechs and under Russian control.

B. Further information was obtained about a number of firms by unofficial visits and by enquiries in the right quarter.

1. Jet Propulsion laboratory at Turnov (Bohemia). This was cleaned out by the Russians in October or November 1945, and the scientists including Germans were removed by the Russians.

2. Radium production plant at Jachymov (Bohemia). The following information about this plant was given by a secretary in the Ministry of Mines in Prague who will produce a detailed report of work going on in this mine. Since 1863 uranium ore has been mined here and utilized for the manufacture of radium. Pre-war production of radium amounted to about 2 grams per year. When the Germans moved in, they destroyed the whole factory. At this time, the entire stock of radium amounted to 20 grams. The Germans put mining on a high priority and only mining was done throughout the 6 years occupation. The ore was delivered by special planes to Germany and Austria.

Before the Russians entered Czechoslovakia they made arrangements with the Allies to alter their western boundary for the purpose of including the Jachymov mine which they considered of such importance. On arrival, they put a strong guard around the mine. It has been reported that they removed the ore by night in trucks, but this is unconfirmed. Since then the Russians have officially left and the mine is under Czech administration though almost certainly under Russian control. The production at present is 1 gram of radium from 10,000 kgms of ore. Engineer Koblitz has been commissioned to put the radium processing plant into production and has been or will be sent to England or the U.S. to study our method of production. It is not yet certain whether the output will go to the Czechoslovak State for medical purposes or will be exported to Russia.

3. POLDINA-HUT at VITKOVICE (Moravia). [...] The Russians have taken over the whole plant.

4. SIEMENS at CESKE BUDEJOVIC (Bohemia). Two factories were seen from the outside in this town. There was a strong guard outside. Work is going on in altogether 17 Siemens factories and according to a Czech staff officer, it is under Russian supervision because only specially authorized Czechs are allowed there.

5. STALIN WORKS at DUCHCOV (Bohemia). [...] The plant is at present guarded by 400 of the Czech militia.

C. General Report on State of Czech Factories.

All factories formerly engaged on war production and many others besides have been nationalized and are under the control of the so-called National Administrator, who in every case is a Communist and has been installed under Russian influence. In almost all cases, these administrators have proved themselves incapable of running a factory with the result that there has been trouble in the form of protests among the employees. In some cases these administrators have already been removed and replaced by more competent Communists.

[...] None of the Russian Naptha promised in exchange for Czech coal and textile products has been delivered.

D. OBZ [...]

History: OBZ is the secret Service of Czechoslovakia. It was formed... on the instigation of the Red Army. [...]

The whole organization is based on the lines of the NKVD. [...]

The Russians are by no means dependent on the OBZ for secret service activities inside Czechoslovakia. They have their own excellent independent agents who in fact guide the activities of OBZ. [...]

[See document photos on pp. 5520–5527.

Vladimir "Val" Rychly was born in the U.S. in 1909 to parents who were immigrants from Czechoslovakia. He grew up speaking Czech, knew ten other languages, and had a celebrated career in U.S. Naval Intelligence. See: Marvin B. Durning. 2007. *World Turned Upside Down: U.S. Naval Intelligence and the Early Cold War Struggle for Germany.* Washington, D.C.: Potomac Books.

Rychly's report demonstrates how little postwar U.S. inspectors were able to learn of wartime German work in Czechoslovakia. This rare visit, by a lone Navy lieutenant, came after many other U.S. inspectors were denied or sent away empty-handed. Rychly's report does not even mention some of the major known wartime German research and development locations in Czechoslovakia such as Skoda in Pilsen. Of the locations that Rychly does list, most he was not allowed to visit, or everything had been removed from them by the time he visited. Where Rychly was allowed to visit a site that was still active, he was closely escorted by the OBZ Czechoslovakian secret service and denied access to any information they did not want him to have.

Virtually all documentation, prototypes, laboratories, and scientists connected to wartime German work in Czechoslovakia were removed to the Soviet Union. Presumably that information is still buried in Russian archives if it can be found and released.

Is there any relevant surviving information about wartime German work in Czech archives that was not removed or destroyed by the Soviets or their Czech allies?

What other information about wartime German work in Czechoslovakia do the U.S. and U.K. have from intelligence reports or from individuals who escaped to the west? What else can be found in U.S. and U.K. archives?

Rychly's report does not necessarily negate other reports about the Weser/Krizik complex being involved with work related to nuclear weapons and advanced rockets. Since the plant was cleaned out by the time Rychly visited, his only official information about Weser was apparently whatever his OBZ escorts wanted him to hear. As shown in item 8 of Rychly's report (A.E.G. at BEDRICHOV), actual work at these locations was much more extensive than admitted, and details of that work were blocked by the OBZ and other Czech officials.

From several available documents, "Pfau" seems to have been a general name for certain types of automated guidance systems for missiles and torpedoes [see for example pp. 5544, 5554; Trenkle 1987, pp. 121, 123].

Rychly stated that the V-4 rocket was actually "completed," so it was far more than a paper design. The fact that Rychly could mention the V-4 without further explanation suggests that the high-ranking U.S. military officials to whom he was reporting were already well aware of the existence and details of the V-4 rocket. Indeed, according to other U.S. military officials (p. 5544), this V-4 had both an increased range and an improved payload compared to the much better known A-4 (V-2) rocket.

Volman was a large engineering design and manufacturing company founded and run in Čelákovice by Josef Volman (Austrian/Czech, 1883–1943). Why were the Germans mass-producing cyclotrons at Volman? They reportedly shipped at least three to other German programs during the war, and had at least three left over that were claimed by the Soviet Union after the war. Were cyclotrons being mass-produced at Volman (and elsewhere) and then being used somewhere for electronuclear breeding?

Note that advanced U-boats were being produced, and in the mountains of central Europe.

Advanced jet propulsion work was being done there too.

This report is strong evidence that from 1939 to 1945, Germans used uranium ore from Jachymov (and perhaps other sources as well) for a secret, high-priority purpose that was not radium extraction:

- The Germans put uranium ore mining at Jachymov on a high priority no later than 1939 and continued until 1945.
- 10,000 kg of uranium ore yields 1 gram of radium, so if the Germans were primarily interested in the radium, extracting the radium at or near Jachymov would reduce how much material needed to be transported by a factor of 10,000,000, and also avoid contaminating Germany with all the waste byproducts of the extraction. Instead, the Germans destroyed the radium-extraction factory at Jachymov in 1939, never replaced it, and transported away all the ore.
- Uranium ore is very heavy, yet instead of using trains or trucks, the Germans used "special planes" to carry away the ore, again indicating a very high priority as well as a sense of urgency. It is also much harder to trace where planes go than where trains go, so this arrangement conferred a much higher level of security too.
- Officially Germany only had one uranium ore processing facility, Auer near Berlin, but the "special planes" also delivered uranium ore to Austria. What facility or facilities in Austria were processing uranium ore? Of the ore delivered to Germany, did any go to facilities other than Auer? Did ore only go to Germany and Austria, or could there have been deliveries to processing facilities elsewhere, such as Poland?
- The extreme level of Russian interest in Jachymov may indicate that the Russians knew how the Germans had been using the ore from Jachymov.]

Brief notes on 17 Czechoslavakia factories and laboratories which were working for the German Navy during the war. Output included torpedo parts, gun mountings, rocket launchers, 30 mm guns, turbines, radar jammers, V-boat parts (including rubber coating), mines, rockets, cyclotrons, aero engines, radium, etc. No technical details. Present production, management, personnel and degree of Russian control and exploitation, all briefly discussed. History and organization of the secret service of Czechoslavakia (the "OBZ"). Czechoslavakia request for British-US assistance in minesweeping the Danube countered by Russian objections. **Brief note on Russian economic espionage.**

(Nation reported on) (Main title as per index guide) (Subtitles) (Make separate report for each title)

BRIEF.—(Here enter careful summary of report, containing substance succinctly stated; include important facts, names, places, dates, etc.)

A. Between 3 January and 22 January, arrangements were made with the Czech'k General Staff to visit a number of plants that had been working for the German Navy during the war. Contact was made with this Staff through the British and U.S. Military Attaches who introduced me to Gen. BOCEK. The Czech authorities granted the permission but informed me that I would have to be escorted throughout by the Czech Secret Police (O.B.Z.). The plants visited were the following:

1. C.S.R. ZBROJOVKA at BRNO (Moravia). This firm has in all some eight plants in a radius of 70 Klms. of BRNO. During the war they produced for the German Navy-:
   Tail portions for torpedos T1 - T4.
   Torps + Mines The gun mounting L.C. 30.
   Ordnance M.K. 303 (a 30mm gun, muzzle velocity 1050, firing 450 rds per minute. To be produced at a rate of
   Rockets 255 per month by December 1944).
   28cm Dusenrohr.
   Rocket launcher for 38cm diving rocket.
   Z.W.1 mine and depth charge ejectors.
   Visierträger L.44.

   When the Russian Tech Control Commission arrived they ordered the firm to continue the production of the above weapons until they withdrew on 1 December 1945. When they withdrew they removed the machinery for building the M.K. 303 and the Rocket Launcher. Also removed were all documents, drawings and a number of leading technicians.

2. PRVNI PRNENSKA STROJIRNA, BRNO (Moravia). Manufactured 60 turbines for Torpedo Recovery vessels of 3000 h.p. Complete Bridge Superstructures with hydraulically operated H.A. guns for type XXI U/Bs. From this plant all documents were removed by the Russians, but no further work was carried out under their supervision.

   Subs

3. BATA, ZLIN (Moravia). Produced the A.B. Geraet, 205 for AEG. Parts for radar jammer for AEG. Certain unspeci-

Subject: Report on Visit to Czechoslovakia.

- -

fied parts of U-boat type XXVI W including the bridge superstructure. M. K. 303 with special type mounting. Rubber for experimental coverings of U-boat hulls.

The Russians maintained production of these weapons in the factory until December 1945, and even now are arranging the further work on a number of articles through their acceptance commissions. Work still continuing is on the A.B. Geraet, 205 and further experiments on the rubber covering for U-boats are being carried out in the laboratory. Apart from this shoes and tires for motor cars are being produced for the Red Army. Among those still working in the factory are 15 technicians from Rhein Metall Borsig.

Subs
Rockets

4. ZIKMUND-CHEMA at LUTIN (Moravia). Manufactured Thoma 1607 (pump). Periscopes apart from lens. Muzzle velocity measuring instruments without use of photo film. Various pumps for U-boats. Experiments on a U-boat pump using water as a medium instead of oil. Rocket powder. Powder for high internal pressure.

This plant was undamaged at the end of the war and Russian technicians arrived and studied with the Czech technicians in the plant until 1 December 1945. All documents and valuable machinery were removed by the Russians who, however, evacuated none of the technicians and scientists.

Electronics

5. STEIN and SPOL at BRNO (Moravia). Manufactured VR 7-9-10-12 amplifiers up to 500 Hz. P.K. 22 and 23 pendulums for U-boats. Radar jammers, 150 of which were completed but never delivered to the Germans.

Everything of interest was removed by the Russians.

Mines
Torps.

6. SCHMIDDING at PODMOKLY (Bohemia). Manufactured Dora mine. L.M.B. (S) 100 completed per day without fuzes. L.M.F. mine. E.M.F. mine. L.M.B. 3. B.M. 1000. Ida fuze 5000 per month. Ingolin torpedo without fuel and fuze.

This plant was originally constructed to produce for the German navy. At the end of the war, the Russians removed certain plant and technicians from Brueckner and Kanis in Dresden to Podmokly where the complete Ingolin torpedo was then put into production. By October 1945 the Russians stopped production, removed the completed torpedoes and other weapons, duplicates of all documents and a number of German engineers to Russia.

7. WESERWERKE at DECIN (Teschen)(Bohemia). A lot of inaccurate reports have been circulated about the work carried on in the vast underground workshops of this plant. It has been reported that cyclotrons were manufactured and that in laboratories work was being carried out on atom smashing in conjunction with uranium isotope 235.

Rockets

In actual fact the following work was carried out:- production of V-1 and V-2. 55mm rockets. Schlange. Wespe. 30mm pneumatic cannon. Remote control rockets.

This plant was very strictly guarded until 1 December 1945, and it is thought that German technicians were still employed there up to that date. The plant has now been evacuated.

Torps
Mines
Radar

8. A.E.G. at BEDRICHOV (Bohemia). Manufactured F.B. Zielsuchgeraet. Pfau. Amsel. Ida 105 mine, accoustic, induction and reacting to change in water pressure. V-1 and V-2 fuzes. The completed V-4. Lichtspiegelanlage.

The German scientists Pfister and Bakes, with whom I had the opportunity to speak, and some 22 other German scientists are still working on the development of the above under Czech supervision for the Russians. The program on which this firm is still engaged is much more extensive than that listed above. Pfister tried to pass me a copy of the complete program of work, but this was seized from my hand by one of the O.B.Z. officials present.

The O.B.Z. official promised that I should obtain a copy of this program in Prague. On arrival there General Bocek gave orders for it to be surrendered to me, but this got to the ears of Colonel Reicin, the right hand man of General Svoboda, who forbade the authorities to let me have a copy.

Both Pfister and Bakes seemed most keen to be of assistance to us.

Nuclear

9. VOLLMANN at CELAKOVICE (Bohemia). Manufactured 3 cyclotrons that were removed to Russia. No work was proceeding in the factory.

Ordnance
Subs
Aeron

10. CESKO-MORAVSKA. KOLBEN-DANEK at SLANY and PRAGUE (Bohemia). Manufactured 3.7 cm SK/C/30 for U-boats. Mounting for LC 39. 20mm C 39 mounting and hydraulic mounting, for use in U-boats. Various shafts for U-boats.

This plant was bombed out entirely and as far as is known the Russians removed nothing. Now manufacturing aero engine Argus type SI 204 and automobile engines.

Subs

11. HAVELKA PRAGUE (Bohemia). Manufactured bridge superstructures and conning towers for U-boat types XXI, XXIII, and XXVI W. Gyro compass for M-boat type 43. Klappe Z 180 for type XXVI.

The chief engineer of the firm carried out a tirade against the management of the works in my presence and was there and then removed by the O.B.Z.

12. ASKANIA PRAGUE (Bohemia). Works in Prague were bombed out. No permission was granted to see the other Askania works which were reported to me by a friendly major of the Czech General Staff as being inaccessible to Czechs and under Russian control.

B. Further information was obtained about a number of firms by unofficial visits and by enquiries in the right quarter.

1. Jet Propulsion laboratory at Turnov (Bohemia). This was cleaned out by the Russians in October or November 1945, and the scientists including Germans were removed by the Russians.

Nuclear

2. Radium production plant at Jachymov (Bohemia). The following information about this plant was given by a secretary in the Ministry of Mines in Prague who will produce a detailed report of work going on in this mine. Since 1863 uranium ore has been mined here and utilized for the manufacture of radium. Pre-war production of radium amounted to about 2 grams per year. When the Germans moved in, they destroyed the whole factory. At this time, the entire stock of radium amounted to 20 grams. The Germans put mining on a high priority and only mining was done throughout the 6 years occupation. The ore was delivered by special planes to Germany and Austria.

TOP SECRET

TOP SECRET   11 February 1946.

Subject: Report on Visit to Czechoslovakia.

Before the Russians entered Czechoslovakia they made arrangements with the Allies to alter their western boundary for the purpose of including the Jachymov mine which they considered of such importance. On arrival, they put a strong guard around the mine. It has been reported that they removed the ore by night in trucks, but this is unconfirmed. Since then the Russians have officially left and the mine is under Czech administration though almost certainly under Russian control. The production at present is 1 gram of radium from 10,000 kgms of ore. Engineer Koblitz has been commissioned to put the radium producing plant into production and has been or will be sent to England or the U.S. to study our method of production. It is not yet certain whether the output will go to the Czechoslovak State for medical purposes or will be exported to Russia.

3. POLDINA-HUT at VITKOVICE (Moravia). Germans are employed in a laboratory here and at Kralovo Polska Strojirna making experiments on the production of a gun barrel by the process of drawing cold steel. It is claimed that by this process a gun barrel can be completed in one minute. The Russians have taken over the whole plant.

Electronics

4. SIEMENS at CESKE BUDEJOVIC (Bohemia). Two factories were seen from the outside in this town. There was a strong guard outside. Work is going on in altogether 17 Siemens factories and according to a Czech staff officer, it is under Russian supervision because only specially authorized Czechs are allowed there.

Synthetics

5. STALIN WORKS at DUCHCOV (Bohemia). Produces synthetic gasoline for the Russian Army. Only a small portion is allotted to the Czechoslovakian State. The plant is at present guarded by 400 of the Czech militia.

C. General Report on State of Czech Factories.

All factories formerly engaged on war production and many others besides have been nationalized and are under the control of the so-called National Administrator, who in every case is a Communist and has been installed under Russian influence. In almost all cases, these administrators have proved themselves incapable of running a factory with the result that there has been trouble in the form of protests among the employees. In some cases these administrators have already been removed and replaced by more competent Communists.

Under the nationalization program a 40 billion kroner deficit is shown by Czech industry. The Russians promised deliveries of steel and other raw materials necessary for the heavy industries of Czechoslovakia, but only 46% has been delivered. The official Russian reason why her promise has not been fulfilled is that the Russian need is greater than the Czech need. It is stated in the industrial circles in Czechoslovakia that the 46% of the promised deliveries was only a gesture of good propaganda for the Russian sponsored Communists in the coming elections.

None of the Russian Naptha promised in exchange for Czech coal and textile products has been delivered.

D. OBZ (Obrana Sluzba Zpravodajska)(Obranna Bezpecnostni Sluzba)

History: OBZ is the secret Service of Czechoslovakia. It was formed in the SSSR under the Czechoslovak Major Svoboda (now General and Minister of War of Czechoslovakia) on the instigation of the Red Army. It was formed within the Czechoslovak brigade of the Red Army. The original members were Russian Commisars in the Czechoslovak Brigade. They formed an independant organization inside the Brigade, the head of which was Sgt. Reicin, now Col. Reicin appointed by General Svoboda.

The whole organization is based on the lines of NKVD. When the Czechoslovak Brigade moved home from the USSR the OBZ took over the entire task of internal security under the guidance of NKGB, the equivalent Russian War time security organization and independent of NKVD.

Development: OBZ has been enlarged under guidance of NKGB. Reliable Communists were sent for special training to USSR, and have returned as officers in the OBZ.

The composition of OBZ at present is 90% either a member of the original Czechoslovak Brigade or reliable specially trained Communists. 5% are reliable untrained Communists and a further 5% are non-political Czechoslovak Citizens who have been appointed to this service for the purpose of giving a harmless output appearance to a purely national security organization.

Present Organization: The OBZ today is composed of several sections working independently:

a. STATE SECURITY UNITS

1. For the safeguarding of industrial plants and Government buildings.
2. For the prevention of sabotage, industrial sabotage, and including of safekeeping of all secret documents from elements inimical to Soviet interests.

b. INTERNAL SPECIAL SECRET SECURITY UNITS

1. For the prevention of infiltration of enemy elements.
2. A political Commisar Service inside the Army along purely Russian lines.
3. An in-tourist service for the purpose of checking the identity and intentions of all travelers inside the country.

c. POLITICAL UNITS

1. To render harmless all enemies of the Czechoslovak Government inside Czechoslovakia.
2. A similar unit employed in the safeguarding of Soviet Communist interests in close colaboration with NKVD. (An example of the activity of this branch is the arrest of subversive agents sent from Czechoslovak circles in London to carry on a political activity against the present State).

TOP SECRET 11 February 1946.

Subject: Report on Visit to Czechoslovakia.

- -

General: The OBZ have carried out up till now no investigations abroad of an espionage nature; they are solely concerned with the Czechoslovak internal matters. Recently, however, it has been reported that 31 OBZ agents have been sent West over the border into the British and USA Zones of Germany.

Agents for political and Economic espionage abroad have been recruited by the Russian Bureau of Foreign Affairs (INU) with a branch in Prague, or by NKVD with agents in Prague. These two offices have only recruited such Czechoslovak agents for these duties who have a special training in the USSR.

Influence of OBZ:

1. For the most part OBZ carries out stooge detective jobs, although they represent a considerable nuisance value.
2. The Russians are by no means dependent on the OBZ for secret service activities inside Czechoslovakia. They have their own excellent independent agents who in fact guide the activities of OBZ.

E. UNOFFICIAL CZECHOSLOVAK REQUEST FOR WESTERN ALLIED ASSISTANCE IN MINESWEEPING THE DANUBE.

When the request to visit factories was made to the Czechoslovak General Staff, I was approached as a Naval Officer by Capt. Stanek, and Major Zeman of the Technical Intelligence Section of Czechoslovak G-2 on the question of clearing certain sections of the Danube or acoustic and magnetic mines which were seriously disturbing the flow of shipping. It was stated that the Russian Army has attempted 4 or 5 times to clear the mines, using hooks and nets. There results were unsatisfactory and ships were still being lost. These two officers who seemed well disposed towards the Western Allies arranged for a meeting in the office of the Czechoslovak General Staff under a Colonel whose technical advisor was Sen. Ing. Capt. Strnad Karel who also bitterly complained of the difficulties on the Danube. Present at the meeting was Major Pavlik of the OBZ, who after hearing of a proposal that USA or British assistance in clearing mines be requested, officially stated that was a matter for the Red Army without whose permission no such request could be forwarded. He stated, however, that if the Soviet Government were still unsuccessful in clearing the mines, they might agree to a formal request being forwarded to Western Allies. All efforts by the Czechoslovak General Staff to influence Major Pavlik to change his mind were in vain.

It is suggested that should a request be made by the Czechoslovak Government for Anglo-USA assistance, it would be an excellent opportunity for certain observers in addition to the Technical minesweeping types to move around in an area otherwise closed, Particularly as minesweeping vessels would have to enter the Danube via the Black Sea.

If our authorities agree that this might be a good opportunity it will be possible to communicate with the Czechoslovak official responsible for this work, and get him to press for the necessary request even if this entails exaggerating the gravity of the mine danger on the DANUBE.

F. RUSSIAN ECONOMIC ESPIONAGE ABROAD

An example of Russian long term economic intelligence is the case of Dr. Hecht, a Czechoslovak Communist trained in intelligence work in SSSR. By some unknown means Dr. Hecht contacted a certain Van Ufen who is either Dutch or German and who has a business connected with shipping on the Rhein. Dr. Hecht, who is heavily financed by the SSSR, proposed that the business be expanded with this money, provided Van Ufen can gain the approval of the authorities. All the information that can be obtained from the Rhein area by the various branches of the firm will be passed direct to the NKGB by Dr. Hecht. (Information received from a reliable source (O.S.S.) inside Czechoslovakia).

BRIEF.—(Here enter careful summary of report, containing substance succinctly stated; include important facts, names, places, dates, etc.)

SUMMARY: The following S.S.U. report, L-1262, dated 19 February 1946, concerns Weapons Research at Kreisel-Siemens-Gema, along with a list of leading personnel, their title and function.

GERMANY/BERLIN : MILITARY

Weapons Research at Kreisel-Siemens- Gems.

The information below comes from a well-placed and fairly reliable source:

1. The Russian technical office in the Gema-Haus in Köpenick is now known as KSG (Kreisel-Siemens-Gema). It is under Navy control and directed by Lt. Col. Sherbok and Lt. Col. Grudnitzki (?).

Apparatus not yet tested by the German Navy is being further developed. These are: depth steering (Tiefensteuerung) for submarines, floating steering (Schwebesteuerung) for submarines, automatic fire control devices (Geschützsteuerung), gyroscopic devices, steering for V-3 and V-4 weapons, aiming devices and gauges. The development is carried to the point of final tests; at the same time plans are made for mass production in Russia.

3. At present about 400 people are employed.

4. About 60 machine-tools are now operating; more are on the way from Morsleben, where an underground factory with about 2000 machines is being dismantled.

5. The Russians succeeded in retaining the most important specialists, many of them former party members. Below (paragraph 9) is a list of the more important employees in each group.

6. The Kreisel group, with the former employees of Kreisel-Geräte G.m.b.H., is carrying on the development of gyroscopic devices and hydraulic steering apparatus. The Siemens group, with the former employees of Siemens-

Apparatebau is working on electrical steering apparatus, particularly remote-control steering and aiming devices. The Gema group is working with remote-control steering, bearing and aiming devices.

7. Wages paid by KSG range from 1 to 7.5 marks per hour. These are 20 percent or 30 percent above the established rates for such work in the Soviet Zone.

8. V-3 and V-4 are about 15 m long and 3 m thick, larger than V-1 and V-2. Propulsion units go into action by groups. After one group has been emptied, it is ejected from the rocket. Steering and ignition are performed by remote control. Hulls for these weapons are said to be built in the Harz Mountains and in a factory near Berlin; exact addresses are not available.

9. Leading personnel of Kreisel-Siemens-Gema are the following:

Name	Title	Function
a. Kreisel Group		
Mummert	Oberingenieur (Chief Engineer)	Abteilungsleiter (Head of Department)
Gudakowski	Ingenieur (Engineer)	Vertreter (Ass't. Department Head)

SUMMARY: The following S.S.U. report, L-1262, dated 19 February 1946, concerns Weapons Research at Kreisel-Siemens-Gema, along with a list of leading personnel, their title and function.

GERMANY/BERLIN : MILITARY

Weapons Research at Kreisel-Siemens-Gema.

The information below comes from a well-placed and fairly reliable source:

1. The Russian technical office in the Gema-Haus in Köpenick [a suburb of Berlin] is now known as KSG (Kreisel-Siemens-Gema). It is under Navy control and directed by Lt. Col. Sherdok and Lt. Col. Grudnitzki (?).

[2.] Apparatus not yet tested for the Germany Navy is being further developed. These are: depth steering (Tiefensteurung) for submarines, floating steering (Schwebesteurung) for submarines, automatic fire control devices (Geschützsteurung), gyroscopic devices, steering for V-3 and V-4 weapons, aiming devices and gauges. The development is carried to the point of final tests; at the same time plans are made for mass production in Russia.

[...] 3. At present about 400 people are employed.

4. About 60 machine-tools are now operating; more are on the way from Morsleben, where an underground factory with about 2000 machines is being dismantled.

5. The Russians succeeded in retaining the most important specialists, many of them former party members. Below (paragraph 9) is a list of the more important employees in each group.

6. The Kreisel group, with the former employees of Kreisel-Geräte G.m.b.H., is carrying on the development of gyroscopic devices and hydraulic steering apparatus. The Siemens group, with the former employees of Siemens-Apparatebau is working on electrical steering apparatus, particularly remote-control steering and aiming devices. The Gema group is working with remote-control steering, bearing and aiming devices.

7. Wages paid by KSG [...]

8. V-3 and V-4 are about 15 m long and 3 m thick, larger than V-1 and V-2. Propulsion units go into action by groups. After one group has been emptied, it is ejected from the rocket. Steering and ignition are performed by remote control. Hulls for these weapons are said to be built in the Harz Mountains and in a factory near Berlin; exact addresses are not available.

9. Leading personnel of Kreisel-Siemens-Gema are the following:

[three pages of names, qualifications, and job descriptions]

[See document photos on pp. 5528–5531.

What exactly was at Morsleben, Saxony-Anhalt? "An underground factory with about 2000 machines" sounds like a very large facility. See also pp. 3433–3437, 3456–3416, 3708, 4922.

Anything being produced and reported by 19 February 1946 would almost certainly not be new technology, but rather simply restarted production of wartime German technology.

Many different projects, with various real names, had been vying for the titles of V-3 and V-4, which would have simply ben the third and fourth projects publicly announced after the V-1 cruise missile and V-2 or A-4 rocket. Thus the V-3 and V-4 rockets mentioned here may or may not be the same as V-3 or V-4 weapons mentioned in other sources.

Note that different components of these V-3 and V-4 rockets were being produced by different surviving wartime German factories: guidance, steering, or other systems at Kopenick, and hulls in the Harz Mountains (Nordhausen, Bleicherode, Gotha, or elsewhere?) and Berlin area (where?).

The V-3 and V-4 rockets described here do not match known or even modified versions of previously documented wartime German rockets. The V-2/A-4 was 1.65 m in diameter ("thick") and single-stage, unlike what is described here. The combined A-9/A-10 was multi-stage but approximately 26 m in total length for both stages, and 4.15 m thick for the lower A-10 stage. It is possible that information given in this report is simply a garbled description of A-4 or A-9/A-10 rockets or modified versions of them. However, given the level of detail in the rest of this report (lengthy lists of names and job duties of personnel working on the projects), it seems much more likely that this description is reasonably accurate, and that the V-3 and V-4 were novel rocket types that have not been previously documented.

If the information provided here is fairly accurate, one plausible interpretation is that it describes a relatively standard A-4 surrounded by strap-on booster rockets that assist with the launch but drop off once their propellant has been consumed. That approach would significantly increase the range and/or payload compared to an ordinary A-4 rocket, and it would be technologically relatively straightforward to implement. A 1.65-m-diameter A-4 with $\sim$ 0.68-meter-diameter booster rockets on opposite sides (or clustered all around it) would be $\sim$3 m "thick" with "propulsion units that go into action by groups" and then are "ejected from the rocket." Is there direct evidence for the development or existence of suitable strap-on solid- or liquid-propellant booster rockets?

Could the described rocket have been a wartime German project that was copied/modified after the war as the Soviet G-2 project (pp. 5560–5562)? Among other configurations, two or more A-4 rockets could have been strapped to the side of a central A-4 to serve as boosters.

As yet another possibility, there are several reasons to believe the described V-3 and V-4 rockets might have been intended to be submarine-launched ballistic missiles:

1. These V-3 and V-4 rockets are included in a list of projects for the German Navy, and alongside numerous projects for submarines.

2. It is known that Germany was actively pursuing submarine-launched versions of the V-1 and

V-2/A-4 that could be launched near the coast of the United States; see for example pp. 5618–5627 and 5628–5660.

3. It is known that German work on submarine-launched missiles was being conducted in the mountains in central Europe and not just on the seacoast; see for example pp. 5640–5645.

4. An A-4 launched from a submarine just off the U.S. coast could travel inland by a maximum range of approximately 350 km with a 1-ton payload, or approximately 280 km with a 2-ton payload (p. 5797). Alternatively, the submarine could keep its distance from coastal defenses and still launch missiles at targets on the coast up to those maximum ranges. (J. Edgar Hoover reported on German plans that "submarines would proceed to within 100 or 200 miles of the United States and then fire these rockets," p. 5626.) However, those ranges would not be satisfactory for targets that were too far from the coast—cities such as Chicago, or manufacturing plants throughout the interior United States. Increasing the amount of propellant and/or using multiple stages would greatly increase the range.

5. In response to attacks by the Allies, Germany rapidly moved its essential wartime manufacturing to less accessible areas (deeper into Europe and/or underground). Thus Germany would likely have expected that if it began to attack coastal targets in the United States, the United States would rapidly move essential industry further inland, and much U.S. industry was already far inland. German war planners would presumably have wanted to have correspondingly longer-range weapons available as soon as possible.

6. Other than the massive A-10 booster stage, other large wartime German rockets (A-4, A-9, and any extended-length versions of them) and postwar Russian rockets directly based on German technology (SS-1/R-1, G-1 design, SS-2/R-2, SS-3/R-5M, etc.) all had a standard diameter of 1.65 m, and varied in length between 14 m and 21 m. Increasing the amount of propellant and hence the payload and/or range could be readily accomplished by simply increasing the length from the starting length of 14 m for the A-4. In contrast, increasing the diameter from 1.65 m to 3 m would:

a. Require large modifications to equipment for producing cylindrical propellant tanks, dome-shaped tank ends, and ring-shaped structural supports for the rocket body.

b. Require major changes to rocket manufacturing areas (often underground tunnels), rocket-transporting trucks or train cars, storage areas, and launch sites.

c. Increase aerodynamic drag losses, which to a first approximation are proportional to the cross-sectional area of the rocket, by a factor of $(3/1.65)^2 \approx 3.3$.

7. The most compelling reason one could think of that would have made German engineers produce rockets that were not much longer than an A-4 but were much wider, despite these serious disadvantages, would be that

a. The rocket needed to carry more propellant than an A-4, in order to have an increased range and/or increased payload, AND

b. The rocket needed to be very compact in order to fit within a submarine or submarine-towed container, so it could only increase in diameter and not length.

8. A 12 October 1947 intelligence report from Russia reported that a team of German specialists was supervising the construction in Russia of "rockets are similar to the German 'V' type but larger in size. This rocket in the shape of a cigar is 16 m long and 2.5 to 3 m in diameter." (See p. 5566.) Those dimensions described in that 12 October 1947 report are very similar to the rocket dimensions described in this 1 May 1946 report.

9. After the war, German engineers in the United States produced the PGM-19 Jupiter (p. 5501) as a candidate submarine-launched ballistic missile (although it was ultimately deployed on land and not in submarines). Jupiter had a diameter of 2.67 m and length of 18 m, not too dissimilar from the dimensions described for the V-3 and V-4. It had a range of 2400 km with a 1-ton payload.]

S.D. 4840/MIS-926047. Headquarters European Command, Office of the Deputy Director of Intelligence. Possible use of Czechoslovak made arms in the Soviet Army and the present status in the Czechoslovak armament industry. Annex A. June 1946 [NARA RG 319, Entry NM3-85M, Box 44, Folder 926047].

It is known that the following plants are producers of scientific warfare weapons: A.E.G. Plant—located at BEDRICHOV; Poldina Hut—VITKOVICE; Siemens Plant—CESKE BUDEJEVIC; and the Askania Works. The A.E.G. Plant produces weapons of a military and secret nature, under the guidance of German scientists. Access is barred to all persons of allied nationality. V-3 and V-4 models presumed to be still there, including all data. Poldina Hut is now producing semi-finished steel and iron products; Siemens—proximity fuses, homing torpedoes, and similar delicate equipment; Askania—fine instruments and laboratory equipment. [...]

A.E.G. at BEDRICHOV specializing in PFAU water torpedo; AMSEL land torpedo; IDA 105, new type mine operating on induction principle; the LICHTSPIEGELANLAGE Donau No. 3 and also "Hawaii" aiming devices for very large guns; muzzle velocity gauges and measuring instruments. "Rommel", a new type of radar (never completed).

SCHMIDDING at PODMOKLY, average production of 100 LMB(S)M mines per day.

BATA shoe works at ZLIN suspected of manufacturing other items of military interest besides shoes, as they still employ fifteen Germans from the RHEINMETALLWERKE BORSIG.

HAVELKA of PRAHA were makers of highly technical armament and equipment for GERMANY.

As a result of widespread bomb damage, many of the leading "Scientific Warfare" plants in GERMANY constructed research, experimental and subsidiary installations in CZECHOSLOVAKIA during the war. Most of these were in the Soviet Zone of Occupation, and those that were not destroyed incident to the "liberation" of CZECHOSLOVAKIA were thoroughly exploited by the Russians during their period of occupation.

All plants presently employing more than 250 employees in CZECHOSLOVAKIA have been nationalized.

During the occupation, and into February 1946, the Russians had practically taken them with their own military personnel and lowered the "Iron Curtain" against foreign visitors.

It is known that the following plants are producers of scientific warfare weapons: A.E.G. Plant - located at BEBRICHOV; Poldina Hut - VITKOVICE; Siemens Plant - CESKE BUDEJEVIC; and the Askania Works. The A.E.G. Plant produces weapons of a military and secret nature, under the guidance of German scientists. Access is barred to all persons of allied nationality. V-3 and V-4 models presumed to be still there, including all data. Poldina Hut is now producing semi-finished steel and iron products; Siemens - proximity fuses, homing torpedoes and similar delicate equipment: Askania - fine instruments and laboratory equipment.

Headquarters Berlin District, United States Army, Office of the AC of S, G-2. 31 October 1946. Special Memorandum No 18. [**NARA RG 319, Entry A1-134A, Box 17, Folder XEI69886 Russian Deportation of German Scientists & Technicians**]

Current deportations of German personnel to Russia came as a complete surprise to officer personnel in Karlshorst and to at least some key figures in Potsdam. [...]

Current Soviet deportation and dismantling activities concerning mostly armament factories and plants, include: [...]

3. Dismantling of Schwarzenberg Wasserstoff and Sauerstoff Werke (Hydrogen and Oxygen works).

4. Reported as completely destroyed were Bleicherode V-2 works and “Program A9” Raketenjaeger plants.

[This report covers wartime German plants that were removed by the Soviets.

One of those plants was the “Program A9 Raketenjaeger” or rocket-fighter plant. Program A9 rocket seems like a clear reference to the A-9 rocket, and fighter or Jaeger denotes a manned flying vehicle. This seems to be further evidence that wartime German plants were mass-producing manned A-9 rockets.

Wartime German hydrogen and oxygen production plants are mentioned in conjunction with the report of V-2 and A-9 rocket programs. Liquid oxygen was widely used an the oxidizer in V-2 (and possibly A-9) rockets. Relatively low-performance fuels such as alcohol and petroleum derivatives were used in rockets. Officially liquid hydrogen, a fuel that was much higher performance but needed to be kept so cold that it was difficult to handle, was not. Yet this report seems to suggest that liquid hydrogen was indeed produced and used by the German rocket programs. That interpretation is supported by other claims that liquid hydrogen was used; see for example p. 5311, 5448, 5381, and p. 5764.

Schwarzenberg is only $\sim$ 20 km from the Jachymov uranium mine. Is that simply a coincidence or were nuclear, aerospace, and other top-priority programs concentrated in that geographical area?]

MEMORANDUM FOR THE OFFICER IN CHARGE

SUBJECT: Plans regarding Construction of Long Range, manned Rocket Bombs

Re: Operation 'MESA'

1. This information has been obtained in compliance with CIC mission referenced above.

2. Exhibit 'A', attached hereto, has been obtained from 0-64-III-K who, in turn, received it from a V-2 specialist who escaped from ZENTRAL WERKE in BLEICHERODE (M52/C 91) to avoid being sent to Russia proper. The exhibit embraces the first outline for the manufacture of manned rocket bombs and was obtained from the files of the research bureau of ZENTRAL WERKE, BLEICHERODE, where it had been sent from PEENEMÜNDE (N55/P83).

3. Because of the technical nature of Exhibit 'A', an accurate translation by this office is impossible. Evaluation: A-2.

APO 755
13 January 1947

MEMORANDUM TO THE OFFICER IN CHARGE

SUBJECT: SCHOEN, Edward

1. Upon request of the SAC, Zehlendorf Field Office this agent had informant Heinrich FEISE bring SCHOEN to this office for questioning this date.

2. SCHOEN gave the following information:

a. He resides with his wife at Berlin-Prenzlauer-Berg, Scherenbergstr 24. He was born 8 January 1907 at Berlin.

b. He was approached in August 1946 by a Soviet official who offered him a job at SOMMERDA (Leipzig sheet J39) constructing V-2 weapons. He was told that he would receive a bonus of 50,000 marks upon completion of the job and was warned that if he did not accept the job he would be taken anyway. He took the job.

c. After the machinery was installed and set up in the factory three rockets were built over a period of eight weeks. These rockets had fifty tons of fuel instead of the twenty five tons of the old V-2. The three rockets were crated 24 December 1946 and a week later they were loaded on a train to be sent to a proving ground or factory 13 km from MOSCOW.

d. There are four hundred mechanics working on electrical parts for rocket weapons at a factory in SONDERSHAUSEN (Leipzig sheet D11). This factory is also a collecting point for engineers and mechanics from which many are sent to RUSSIA. There are no mass shipments but individuals are sent, some of them against their will. SCHOEN knows many engineers who are willing to come work for the Americans.

3. AGENT'S NOTES COMMENTS AND RECCOMENDATIONS: SCHOEN has been turned over to Captain BIERMANN of FIAT.

"...Three rockets were built over a period of eight weeks. These rockets had fifty tons of fuel [probably thrust, a translation error] instead of the twenty five tons of the old V-2. The three rockets were crated 24 December 1946..."

V. L. Rychly. Intelligence Report 324366. 13 November 1946. Subject: Former German Factories Located in Czechoslovakia. [NARA RG 319, Entry NM3-85A, Box 2126, Folder 324361 THRU 324370]

Following information on former German factories located in Czechoslovakia was obtained during an unconducted automobile trip to northern Bohemia (formerly Sudentenland) during the days of 9 and 10 November 1946.

1. AEG FACTORY, BEDRICHOV

Prior to German occupation of Czechoslovakia this plant was engaged in the production of fine table linen. During the first raids on Berlin a section of AEG research department was moved into this factory. Some of Germany's finest apparatus was concentrated in the spacious factory, and a large cement basin was built for testing aerial and naval torpedoes. The German Scientists and Technicians were engaged in the development of the following:

- a. Aerial and Naval Torpedoes
- b. Guided Torpedoes
- c. Guided missiles
  - (1) Ground to ground
  - (2) Ground to air
- d. Supersonic missiles

During an inspection of this plant made in November 1945, the German Scientists continued with their work under Soviet supervision.

Present Status

During the first days of November 1945, the entire plant was evacuated from Bedrichov. The testing basin was destroyed. All scientific apparatus was removed and consolidated in the AEG plant in Podmokly, Czechoslovakia, Ustecka ulice 20, under the supervision of the Czechoslovak Ministry of National Defense.

2. AEG FACTORIES in BENESOV

As the factory in Bedrichov, so the largest milling factories in Benesov were requisitioned by the Germans during the period of occupation in Czechoslovakia. A conducted inspection of both plants in November 1945, revealed that research in Benesov was conducted on a lesser scale. However, both factories in Benesov remained under Soviet supervision till December 1945, when they were partially evacuated by the Soviets.

Present Status

During the first days in November 1945, the remaining research facilities were removed under the order of Czechoslovak Ministry of National Defense and moved to the AEG plant located in Liberea, Czechoslovakia.

3. W. SCHMIDDING, POMOKLY

Originally built by the German Kriegmarine, this plant was engaged during the days of war in the development and production of sea, rive and land mines. The W. SCHMIDDING research department completed for the German Luftwaffe,

a. The solid fuel-rocket drive

b. Gasoline burning-power

and conducted successful tests on the Ingolin torpedoes for the Kriegmarine.

Present status

Now completely nationalized and under the supervision of Krizik and Spol (Krizik Corporation—Specialists in Radio, Radar, etc. equipment), this plant located on Ustecka Ulice 30, is engaged in the production of cast aluminum household products [...] The plant was reconverted to peace production. However, the research department remained intact. No contact could be made with the German Nationals employed in this department to obtain complete details.

4. COMMENT

The liquidation of the AEG Factory in Bedrichov and the AEG factories in Benesov, together with the consolidation of all scientific apparatus in Podmokly and Liberec, is the first indication that the Czechoslovak Government is interested in setting up a large organization to conduct research and development of weapons. The Ministry of National Defense in Czechoslovakia is determined to take the advantage of the advanced wartime German work in this field. [...]

[This report by Rychly confirms some of the observations from his earlier report. Note that the wartime German facilities in Czechoslovakia were equipped with “Germany’s finest apparatus,” filled with German scientists, and working on a wide range of high-priority research programs. This was a very important area, and virtually all of its wartime information, products, facilities, and personnel were removed by the Soviet Union without much opportunity for U.S. and U.K. inspectors to ever learn about them.]

Egmont F. Koenig. MIS-326058. Report No. E-174-46. Office of the Military Attaché, American Embassy Prague. 20 November 1946. Subject: Czechoslovak Research Center. [NARA RG 319, Entry NM3-85A, Box 2138, Folder 326051 to 326060]

[...] Approximately 400 German technicians have been retained by the Czechoslovak army, and are being employed on work involving research on guided missiles and rockets.

[See document photo on p. 5542. Brigadier General Egmont F. Koenig (1892–1974) was the U.S. military attaché in Czechoslovakia from January 1946 to May 1947. He had a distinguished military career, and his reports of leftover wartime advanced German technology in postwar Czechoslovakia should be taken very seriously. For more information, see:

Figure E.168: Top: LaVerne Baldwin to L. E. Seemans, 22 November 1946. Bottom: U.S. Naval Attaché Prague. 18 November 1946 [NARA RG 77, Entry UD-22A, Box 175, Folder World].

Egmont F. Koenig. Dispatch No. A-161-46. Office of the Military Attaché, American Embassy Prague. 20 November 1946. Subject: German V-Weapons in Czechoslovakia. [NARA RG 319, Entry NM3-85A, Box 2144, Folder 326851 THRU 326860]

Subject: German V-Weapons in Czechoslovakia.

1. It has been determined with a fair degree of reliability (B-2) that the "V-4" weapon removed by the Russians from Bedrichov was the nose of a surface to surface guided missile, referred to as the "Pfau-2".

2. This nose had a new and more powerful charge, and missile itself was reported to have considerably increased range over the A-4. (B-3)

3. There are two reports as to the type of head delivered to the Russians:

a. That it was a homing device directed at radio stations or along radio beams. (C-3)

b. That it was a "Kommandogeraet", recording altitude, velocity, and other data of the missile. (C-3)

4. Attention is invited to our report No. R-164-46, dated 13 November 1946, Subject: Former German Factories located in Czechoslovakia [see p. 5540], which informs you of the complete dismantling of the research installations at Bedrichov [AEG factory at Bedrichov/Friedrichsthal/Benesov nad Ploucnici], and their move—in toto—to the new Czechoslovak army research center at Podmokly. (A-1)

5. It has also become known that under the "Two-Year Plan", the army has requested a total of eighteen billion Korunas for research and development. Eleven billion kcs for 1947 and seven billion kcs for 1948. (B-2). For a small country like this, such sums are astronomically profligate.

[All research in Czechoslovakia was ultimately turned over to the Soviet Union, although the postwar Czechoslovakian government initially tried to operate independently. If that government was willing to invest an "astronomically profligate" amount of their money in research and development at former German installations during the very lean years immediately after the war, they must have been extremely impressed by the wartime German technologies that remained at those installations. What exactly were those, and where is the documentation for them now?

From several available documents, "Pfau" seems to have been a general name for certain types of automated guidance systems for missiles and torpedoes [see for example p. 5554; Trenkle 1987, pp. 121, 123]. The "Pfau-2" mentioned here was apparently the guidance system of a very large missile, the V-4, which was described in this document as having greater capabilities than the A-4 (V-2). How advanced and how accurate was the guidance system?

How much payload could the V-4 missile carry? Was the "new and more powerful charge" a conventional explosive or something else?

What was the "considerably increased range over the A-4"? How large was the V-4 missile, in order to have had both an improved payload and an increased range?

For Rychly's statement that this V-4 had actually been completed, see p. 5516.]

V. L. Rychly. Intelligence Report 339171. 9 December 1946. Subject: Czechoslovakia—Scientific and Technical Institution—Re-establishment of. [NARA NARA RG 77, Entry UD-22A, Box 175, Folder World; and RG 319, Entry NM3-85A, Box 2229, Folder 339171 to 339180].

SUMMARY

The Czechoslovak Ministry of National Defence decided to re-establish its pre-war Scientific and Technical Institution (V.T.U.—Vedecky Technicky Ustav) after the Soviet refusal to share their latest military developments with the Czechoslovak Army. According to Czechoslovak members of the V.T.U. in the Czechoslovak General Staff at Praha, Czechoslovakia will base its research on the latest German military developments that remained in Czechoslovakia after German occupation and the U.S.S.R. liberation.

1. The U.S.S.R. was cognizant of the fact that the Germans dispersed many of their important research installations in Czechoslovakia in order to prevent their destruction by the allied bombers or to remove them from territories in danger of being captured by the allied forces. Colonel J. Zeman member of the Scientific and Technical Institution (V.T.U.–Vedecky Technicky Ustav) in Praha claims that the Soviets in Czechoslovakia followed a carefully prepared plan for the exploitation of German research sections, and thus gained a clear insight into the military research conducted by the Germans in Czechoslovakia at the end of the war. Surprisingly enough, the German factories and research sections were not heavily damaged by allied bombings or destroyed by the Czechoslovak and foreign slave labor in their enthusiasm over liberation.

2. The Czechoslovaks, totally disorganized after their liberation, were not allowed to enter the German military establishments taken over by the Soviets. For this reason, the Czechoslovak General Staff was ignorant of the value of research apparatus that was left in Czechoslovakia by the fleeing Germans. They could not determine the physical conditions or the military value of the various German-owned or German-controlled research facilities. The Czechoslovak as well as the United States and British exploitation teams were unable to enter or examine most of the equipment the Germans left in Czechoslovakia. Thus U.S.S.R. was in a preferential position to obtain sufficient information on developments by the Germans, including in many cases models or actual weapons.

3. The Czechoslovak General Staff assumed, according to Major F. Vokoun from the V.T.U., of the Czechoslovak General Staff, that the technological knowledge possessed by the Germans would be made available to the Czechs by the Soviet Technical Commission. However, as all attempts failed to obtain such information from the Red Army, the Czechs with the help of their technical personnel made every effort to rescue everything that was not tagged and sent to Russia. Many German institutions that were not labelled by the Soviets as war-booty fell into the hands of the Czechoslovaks. In other cases, German nationals co-operated with the Czechs in hopes of better treatment.

4. As the Scientific and Technical Institution (V.T.U.) started to function again, two research sections were fully equipped and ready to continue with the research on the developments made by the Germans. One such section of the V.T.U. is located in the rear of the Czechoslovak General Staff Building in Praha, the other in Podmokly (Northern Bohemia). Staff Captain F. E. Zeman

of the V.T.U. in Praha revealed that the proposed plan in the military field for the next two years (1947–1948) is the continuance of research on the latest German developments in the following fields:

(1) Electronics:
  (a) Proximity fuzes
  (b) Acoustic proximity fuzes
  (c) Infra-red devices
  (d) Infra-red proximity fuzes

(2) Guided missiles

(3) Rockets:
  (a) With solid fuel drive
  (b) With liquid fuel drive

(4) Hypervelocity guns:
  To be developed:
    Heavy calibers at Skoda
    Light calibers at Zbrojovka, Brno

5. Included in the Czechoslovak estimates for the two years 1947–1948 is the immense sum of 18,000,000,000 Czechoslovak crowns, designated as the Secret Fund set aside for the Ministry of National Defence. Just how much of the secret fund will be allocated to military research could not be reasonably determined, but it is generally assumed that the Scientific and Technical Institution will receive a fairly large appropriation.

MIS 467726. 25 May 1948. Location SKODA Underground Factory [NARA RG 319, Entry NM3-85A, Box 3025. Folder 467721 thru 467730].

A friendly Czech source reported that efforts are being made by several SKODA engineers to reopen the underground factory at HABERSDORF (HABENDORF N51-F65) near PODMOKLY. The plant was built by the Germans and was closed after the war. SKODA intends to manufacture Bofors guns and other light anti-aircraft guns there if it is reopened.

MIS 495076. 7 September 1948. Czech Technical Military Institute (VTU) [NARA RG 319, Entry NM3-85A, Box 3201, Folder 495071 thru 495080].

Summary

The Military Technical Institute, the VTU (Vejensky Technicky Ustav), consists of armament, artillery, ammunitions, infantry weapons, optical, electrotechnical, machinery, chemical and related departments.

The Institute conducts experiments with new equipment and weapons, especially those which are assigned for use by the armed forces. Because of the lack of materials which can be obtained only in the western countries, considerable time is spent experimenting with the material left by the Germans. Both German and Russian armament and arms are tested and compared, but so far, no standardization of equipment has been established.

The Technical Institute has been greatly affected by the coup d'etat. The installing of Communists in key positions has greatly decreased the efficiency of the Institute. [...]

REPORT

The Military Technical Institute (VTU—Vejensky Technicky Ustav)

A. Organization

[...]

2nd (High-voltage electrotechnics) Section

[...]

FRANK, [Helmar] Dr. civilian, graduate engineer (Communist) (German national)

B. Locations

1. Most of the sections of the institute are located in the VTU Building in PRAGUE/Dejvice, Ulice Tatranakeho pluku. Outside PRAGUE are sections which were attached to the VTU in 1945 and sections which were established in places where the Germans had left material, as in the case of the following sections:

a. 1st Section of II. Department is located at KBELY near PRAGUE. Before the war, the Telegraph Ordnance and Stores (military) were located on the same premises. The Germans later converted it into a branch of the "Ostmarkwerke". In 1945 the Section was divided into two parts:

(1) Military (VTU, II/1.) which did research and development

(2) Production.

This separation took a large plot of land and the greater part of the buildings from the army.

b. Television Section of II. Department is located in TANVALD where the Russians concentrated the material left in the country by the Germans.

c. 6th Section of I. Department is located in PODMOKLY, where the German Army constructed the "Schmidding" factory which made parts for jet weapons, such as the V-1 and V-2. In 1945, remnants of electrotechnical material, pertaining mostly to the remote control of rockets and similar weapons, were gathered from different regions in Northern Bohemia and concentrated in the school in PODMOKLY. There was no documentation for this material. After the war, five German technicians remained in PODMOKLY and are now working for the VTU.

The electrotechnical group was transferred from PODMOKLY to PRAGUE in the autumn of 1947 and was established in the so-called "JENERA LKA" in the SARECKE UDOLI. [...]

C. Working Method of the VTU

[...] After the [German] equipment was collected, Czech experts had to study it in order to become up to date with the scientific developments made during the war. These difficulties have been practically overcome and the institute is now beginning to work more systematically. However, there is still a very serious shortage of experts. [...] The situation is especially difficult because the Czech electrotechnical industry is unable to produce valves, klystrons and magnetrons, all of which must be bought abroad. As a result, the VTU spends considerable time developing German material to meet the existing requirements.

D. The Work of Individual Departments

[...] b. II. Department—Electric Engineering

(1) Several sets of German radar equipment were sent to the Institute. After assembling them, the Institute found enough parts to construct three permanent radar stations, one radar train and one anti-aircraft battery train.

The installation of the stations and adjustment of trains have been carried out by the Skoda works. The Military Technical Institute retains control of the equipment.

(2) The wireless receiving and transmitting set "SKRIVANEK" is the only wireless apparatus worth mentioning. The "SKRIVANEK" was constructed for gliders. The range is about 100 km.

(3) The German production of teleprints, ciphering and coding machines is being exploited and developed. This task has been assigned to the Elplys firm in PODMOKLY.

(4) Telephone stations and centrals with multi-channel connections are being established. These are also of German manufacture.

(5) Television parts left behind by the Russians have been improved and a camera, transmitter and receiver (with 625 lines) have been constructed. This set was exhibited in the international radio exhibition (MEVRO). The Sokol festival was broadcast as a test. Almost all the parts of this equipment were manufactured in the Military Technical Institute, including the Braun tubes.

(6) Some German inventions on infra-red lights have been deposited at the Praha University and are being worked on. The work proceeds slowly because of the manpower shortage. Visibility achieved is about 200 meters. [...]

d. IV. Department—Chemical

[...] (2) A cheaper fuel based on some artificial substances (bakelite) is being considered for rockets. The tests have not shown much progress.

(3) Atomic science is not handled by the Institute. The JACHYMOV uranium deposits are under Soviet control and are watched by the Red Army. Only activity is liaison with the Ministry of Health on radium research.

MIS 544782. 29 March 1949. Radar Factory Near JABLONEC Reported [NARA RG 319, Entry NM3-85A, Box 3518, Folder 544781 thru 544790].

The source reported information gathered from an underground organization to the effect that there is an electrotechnical factory within three or four kilometers of JABLONEC which has produced several radar sets. (B-2) The source reported that a GERMAN specialist, name unknown, was directing the organization, and that this GERMAN was recently taken to the SOVIET UNION. In addition, SOVIET authorities removed all radar sets from the factory except six. (B-6) The source also reported several active radar sets at RUDOHORI Mountain near FALKNOV. (B-3) The source confirmed the presence of an active radar set on PRAHA Mountain. The set was described as being of GERMAN origin. (B-2)

COMMENT: This office is unable to locate RUDOHORI. A British source reported the radar set on PRAHA Mountain is of the Jadgschloss type. Although the VTU electrotechnical installation at TANVALD is 9 kilometers east of JABLONEC, it is probable that TANVALD was the subject location.

Sketch C

Detailed plan of the VTU compound at Podmokly. This sketch forms and enlarged part of Sketch B and shows the main VTU compound, except for the buildings numbered 1 through 5, 13, 16, and 17, which are located outside the main compound. The key numbers correspond to those shown on Sketch B. These have in some instances been subdivided (e.g. 8, 8a, 8b, 8c) in order to show details within larger objects. Other objects which were not shown on Sketch B appear on Sketch C under key numbers 18 through 44.

Key to Sketch C

6a. Storeroom R-1
6b. Storeroom R-2
6c. Storeroom R-3
7a. Underground concrete shelter (about 6 meters deep), used as a testing room for rockets
7b. Underground concrete shelter (like 7a); storage of liquid-driven rockets
8. Ammunition dump
8a. Gunpowder storage
8b. Storeroom P-2, for ignition boxes and detonators
8c. Store P-3, for projectiles
9. Swimming pool (water cistern)
10. Testing room for turbine motors
11. Coal storage
12. Guard house
12b. Corridor inside guard house
14. Main gate
15. Trees
18. Mines (showpieces)
19. Fuel tanks for turbine motors
20. Sentry
21. Mobile oxygen plants
22. Torpedo parts
23. "Goliaths" (small armored vehicles)
24. Oxygen plant
25. Sloping drive to underground shelter (laboratory)
26. Mobile electrical laboratory
27. German rocket-launching mortars
28. Stabilization fins of V-2 (showpiece)
29. Storage of packing cases
30. Stores of various materials
31. Glider plane
32. Oxygen plant
33. Chimneys for exhaust gases from underground laboratory
34. Oxygen plant
35. Methyl alcohol tanks
36. Gun carriage
37. Heads of Henschel rockets
38. Cases with Henschel rockets
39. Cases with Henschel rockets
40. Cases with metal fuel bottles for rockets
41. Dump of iron pipes
42. Dump of iron pipes
43. Gas station
44. Hydrant

Figure E.172: Pages from a 20 June 1949 CIA report on the Soviet use of German technologies at Podmokly [https://www.cia.gov/readingroom/document/cia-rdp83-00415r003100040008-4]. Why does this report remain heavily redacted even today?

Central Intelligence Agency Information Report 25X1A. German Radar and Electronic Equipment Seized and Developed by the Russians. 1 November 1949. [https://www.cia.gov/readingroom/document/cia-rdp82-00457r003600120008-5]

1. AEG Plant at 35–38 Drontheimerstrasse, BERLIN-N 20. [...]

e. Remote Control Mechanisms for Searchlights, Aircraft Armament and Radar Sets; Command Guidance Equipment for V-Missiles

In quantity production in BERLIN, further developed in BENSEN [BENESOV NAD PLOUCNICI].

f. Remote Control "BRIGG" Type Receiving Set

Presumably for bombs and V-missiles; wave length about 25 cm, modulated with audio frequencies, developed by the Telefunken Firm. The licensed construction of these sets was prepared in BENSEN late in 1944. Incomplete sets and records were secured by the Soviets in BENSEN. [...]

k. "S-30" Designated "PFAU"

An automatic pilot for the "LTF-5b" aircraft-launched torpedo; developed in BENSEN. About 300 sets were manufactured by the end of the war. [...]

Source is not fully informed on the nature of the technical records secured by the Soviets in the BERLIN AEG Plant.

2. AEG Branch Plant in BENSEN, County of TETSCHEN-BODENBACH, Czechoslovakia

In order to be safe from air attacks, a section of the BERLIN "AEG Fabrik Drontheimerstrasse" was transferred to BENSEN in July 1943 and installed in the BENSEN and FRIEDRICHSTHAL near BENSEN textile plants operated by the ALTAUSCH Firm. [...]

The plant had about 1,000 employees including foreigners (Frenchmen, Belgians, Dutchmen, Russians). Czechs were not employed in technical departments; in other departments there were only two or three of them. Plant manager was Dr. Ing. WERNER, a German.

After the German surrender the plant was declared Czech state property. The plant was not damaged during the war. [...]

Soviets, and later Czech engineer commissions appeared at the plant from June through August 1945 to familiarize themselves with the war production formerly conducted at the BENSEN Plant. The Soviets seized all original blueprints and prototypes produced or developed there. The Czechs removed everything that the Soviets had left.

The following engineers were employed by the Czechs:

(1) Graduate Engineer Rolf PACKES [BAKES—see p. 5516] (for mine ignition mechanisms)

(2) Graduate Engineer Karl PFISTER (for remote control mechanisms)

(3) Graduate Engineer MENDEL (for the "PFAU" Set)

(4) Graduate Engineer WITT

(5) Graduate Engineer Vitaly GROSSE (for mine ignition sets)

(6) Engineer KIRSCH

(7) Engineer FROEHLING (for remote control sets)

(8) Engineer STOLL

These engineers first worked in BENSEN, in the BODENBACH plant of the Czech "VTU" Institute since late 1945, and since 1947 in the PRAGUE "VTU" Plant. [...]

The developmental work of the AEG was continued by the BODENBACH Military-Technical Institute (VTU). Since no Czechs were employed in AEG plants during the war, the further development and reconstruction of the sets was possible only with the help of German technical personnel.

The report confirms the previously reported activities in the field of radar techniques, of remote control devices, electro-acoustics and proximity fuses. [...]

The "Schmidding" Firm (W. Schmidding, Copper and Aluminum Force, Manufacture of Apparatus and Machines in KOELN-MANNFELD) operated a branch plant for rocket power plants in BODENBACH. Remote-controlled bombs and propelling charges of powder for AA rockets were developed here, and parts for V-2 missiles and torpedoes were manufactured in this plant. The turbo-jet power plant of type 003 was manufactured there at the end of the war. This confirms a previous report.

[During World War II, the main AEG factory in Berlin produced state-of-the art guidance systems for missiles and torpedoes. In July 1943, in order to escape from Allied bombing, parts of the AEG factory in Berlin were evacuated to repurposed previously existing factory buildings in the two villages of Bensen (also known as Beneschau or Benesov nad Ploucnici) and Bedrichov/Friedrichsthal in northern Bohemia. For the rest of the war, they operated there, along with a previously existing AEG factory in the industrial village of Bodenbach (Podmokly). See pp. 5540–5541.

(That entire region of Bohemia was densely filled with electronics factories, such as another AEG plant in Reichenberg/Liberec, many Siemens factories in Budweis/Ceske Budejovice, the electronics SS trust Getewent at multiple locations, etc.)

One of the most important weapons produced in this area during the war was the V-4 missile. It was described as being considerably larger than the V-2 and possessing a more sophisticated guidance system, designated PFAU-II. The factory in Bedrichov/Friedrichsthal assembled the complete V-4 or at least its nose, integrating all the guidance components of the PFAU-II system produced together with the other two AEG factories in Bensen and Podmokly. Bedrichov is where the Soviets found a complete nose of the V-4, including its guidance system. See pp. 5516, 5544.

This background information helps to explain why even in 1949, the CIA was still interested in these former Bohemian German electronics plants, especially with regard to how they could provide advanced weapons technologies for the Soviet military.]

Former Branch Plant of the Schmidding Firm in Bodenbach-Podmokly and Schmiedeberg. 10 May 1950.

[https://www.cia.gov/readingroom/document/cia-rdp82-00457r004800590008-4]

1. Main Plant:

a. Schmidding Plant in Koeln-Niehl. This firm is an old copper forge, formerly in Koeln-Raderberg. During the German rearmament the plant was transferred to Koeln-Niehl and branch plants were set up in Hannover, Bodenbach (N 51/F 56) and Schmiedeberg (N 51/K 83). [...] Managing director of the Bodenbach branch plant was a Herr Mohr whose present whereabouts are not known.

b. A recoil projectile, allegedly with the type designation Rheingold, was under development. [Redacted sentences.] Propulsion unit: Binary [liquid fuel + oxidizer] rocket. The development engineer of this projectile was unknown. It was, however, developed under the control of the chief engineer Dr. Kleiner who went to Argentina. This projectile has not been fully developed. However it was in the testing state and was displayed, after the German surrender, together with other products in the firm's show room.

c. Other weapons produced by the firm:

An AA rocket with an estimated length of 700 mm and a diameter of 200 mm. No details available. Twenty thousand powder-propelled rockets of a type similar to the "SG-41", serving as an assistance for take-offs and braking used by jet fighters, were also manufactured. Another Jato, the "SG-2", a binary liquid rocket, was fully developed by Schmidding and produced in one series. [Redacted sentences.]

d. Work for Peenemünde:

Only the building under license of combustion chambers for the V-2 was planned. A model combustion chamber with nozzles was available and was on display in the showroom after 1945. [...]

Headquarters Berlin Command, Office of Military Goverment for Germany (US). 11 December 1946. Special Intelligence Memorandum No. 48. Subject: V-2 Production in SovZone. Source: Extremely Reliable. D-138175. [NARA RG 319, Entry A1-134A, Box 29, Folder ZA 019293 Soviet Guided Missiles, Rockets and V-Weapons Research, Development and Production Vol. 1, Fldr. 2 of 3. See pp. 2960–2961.]

BLEICHERODE in the Harz mountains is still doing fine in the production of V-2 rockets. It was reported from this office that dismantling was going on, but it was stopped as of 1 December. The general procedure for dismantling of installations very dear to the Soviet heart is the following as illustrated best by BLEICHERODE.

As soon as Soviet troops took over the V-2 plants, they did everything in their power to get it reorganized and re-equipped. As soon as this was done, they started production. When they saw that the finished product was satisfactory, they began to dismantle the plant for the first time. The dismantling was not carried through completely, but was halted as soon as about half was taken. Together with the machinery some personnel was taken out, to be shipped to the USSR in order to set up the machinery which was confiscated and complete it with more later.

In the meantime the plant in BLEICHERODE was being rebuilt under supervision of German and Soviet engineers. Once rebuilt, production was started all over again and as soon as satisfactory results were achieved, the dismantling was continued. In this way, Soviet authorities enrich their own country by building up some priceless industries and on the other hand they see to it that the original plant in Germany is reconstructed and re-equipped after each time. Thus, they would be able theoretically to continue an uninterrupted flow of industries from Germany to the Soviet Union.

This procedure is known to have been applied to all V-weapon plants in BLEICHERODE, NORDHAUSEN, GOTHA and BERLIN. In BLEICHERODE the installations were dismantled for the fourth time; in NORDHAUSEN for the sixth time; in Berlin only once; conditions in GOTHA are unknown. [...]

All radio and remote control equipment is manufactured on subcontract by the former SIEMENS Plant in ARNSTADT (Thuringia) while all other parts are manufactured directly in BLEICHERODE. The radio equipment will enable the rocket to send back to base 24 different signals within three seconds, mainly about altitude, airspeed, groundspeed, steering reaction and television view of the objective. [...]

[The above text was also retyped verbatim as: A. H. Graubart. 21 December 1946. Subject: GERMANY/RUSSIA Industry and Industrial Resources. [NARA RG 38, Entry 98C, Box 12, Folder TSC # 3301–3400]

The above document demonstrates that there were many leftover wartime German facilities capable of producing complete rockets or parts for rockets, not just the known Nordhausen plant. Also, the Soviets employed what was apparently a wartime facility in Arnstadt that produced remarkably advanced rocket guidance systems.

Also note that the postwar Russian rocket program is completely indebted to German engineers, technologies, and even factories. Even in the years after the war, the Germans were essentially providing all the expertise, labor, and materials to produce several fully functional copies of each of their wartime factories and then ship those to the Soviet Union, while the Soviet Union ultimately reaped the financial rewards, military power, and technological recognition extracted from those German creators and creations.

Note that the Soviet Union not only shipped hundreds of existing German factories and laboratories to the Soviet Union, but it forced Germans to repeatedly rebuild those facilities and then ship them again. That multiplied both the number of factories and laboratories shipped to the Soviet Union, and also the postwar burden on German science and industry, by several fold.]

INTELLIGENCE DIVISION
W. D. G. S.

Figure E.173: In August 1947, the U.S. War Department General Staff (WDGS) Intelligence Division wrote a report summarizing what they had learned about "Soviet Exploitation of German Science." Even after so many decades, that report remains classified and unavailable to the public. Why? What information is in the report? [NARA RG 319, Entry NM3-82, Box 2899, Folder Project 3837]

Subject: Guided Missiles—USSR. Reference No. 478-13. SD-5820. 7 August 1947 [NARA RG 319, Entry NM3-85M, Box 170, Folder 929657.]

[p. 1:] A limited amount of information has been received about the location of G.M. [Guided Missile] research centres in the U.S.S.R. The most interesting feature was a report which stated that the old Inst. RABE, removed from the NORDHAUSEN area of the Soviet Zone had been split into seven distinct groups. This report is the work of one man, but since the information is, piece by piece being confirmed, the data is passed on with confidence. [...]

[p. 4:] When further questioned, this subject said that he believed Guided Missiles were being produced in the U.S.S.R. He spoke of a huge underground factory at ARNSWALDE in the Polish Zone, which, he said, is intact, and production is in full swing. He spoke of the very heavy guards on the place, that the only railway line in the vicinity terminates at the factory, and that he has seen large railway flat wagons leaving covered with tarpaulins. [...]

[pp. 7–8:] As Director General GROETTRUP controlled all the details of production. Among the special projects under his control were the re-construction of the A-4, G-2 and A-9, the possibility of using steel rockets for stratosphere flight, developments for the calculation of course (both electrical and optical), and airframe developments. He registered the formula for KRAFTSTOFF GRUEN with the Russians and took an active interest in all aspects of the work connected with modifications to the G-2. [...]

[p. 14:] Any list of German scientists would seem to be incomplete without mention of Professors HERTZ, STEENBECK and MANFRED von ARDENNE. Hertz won the Nobel Prize in 1926, and the other two can be rated almost as highly. Mention of these men has not been made before because we believe that they are engaged on Nuclear Physics. They are all believed to be at SUCHUM KALE on the Black Sea Coast. [...]

[This is a 14-page report, not counting its cover sheets, so only a small amount is quoted here. Most of the report is devoted to providing the names, research tasks, and believed locations of German rocket engineers who were working on ballistic missiles and rockets in the Soviet Union and/or East Germany after the war. The large numbers of German engineers who are named and their listed tasks demonstrate how utterly dependent the postwar Soviet missile and rocket programs were on German-speaking designers, craftsmen, and experts.

This document also lists some wartime German rocket projects that were re-constructed after the war by German engineers working for the Soviet Union. Of those listed projects, the A-4/V-2 is well known. However, the inclusion of the A-9 in this list may suggest that production and testing of the A-9 progressed much further during the war than has generally been acknowledged. Most intriguingly, the inclusion of the “G-2” in the list (using the designation by which it would have been known to the report’s source, who was quite familiar with Soviet-sponsored, German-designed rocket projects in 1947) suggests that the postwar Soviet G-2 rocket project (pp. 5561–5562) was directly based on wartime German work. Can other documentation of that wartime German work be found? How far did work on the original German G-2 progress during the war? Presumably it would not have been called the “G-2” in wartime Germany, but would have had some other designation. Was the original German G-2 the same as the V-3/V-4 mentioned in Czech and other documents (pp. 5516, 5532, 5535, 5544), or was it another rocket entirely?

The above report appears to be the only known mention of a huge, highly secret, underground factory in Arnswalde (now Choszczno, Poland) that was built and operated by Germany during the war, and restarted by the Soviet Union after the war. The factory seems to have produced something that was quite large and quite secret. This document implies that it was rockets (possibly more advanced than the A-4/V-2 based on the level of secrecy and security). Can other archival documents related to that underground factory be located? Could industrial archaeology be conducted at that site now to shed more light on what it produced?]

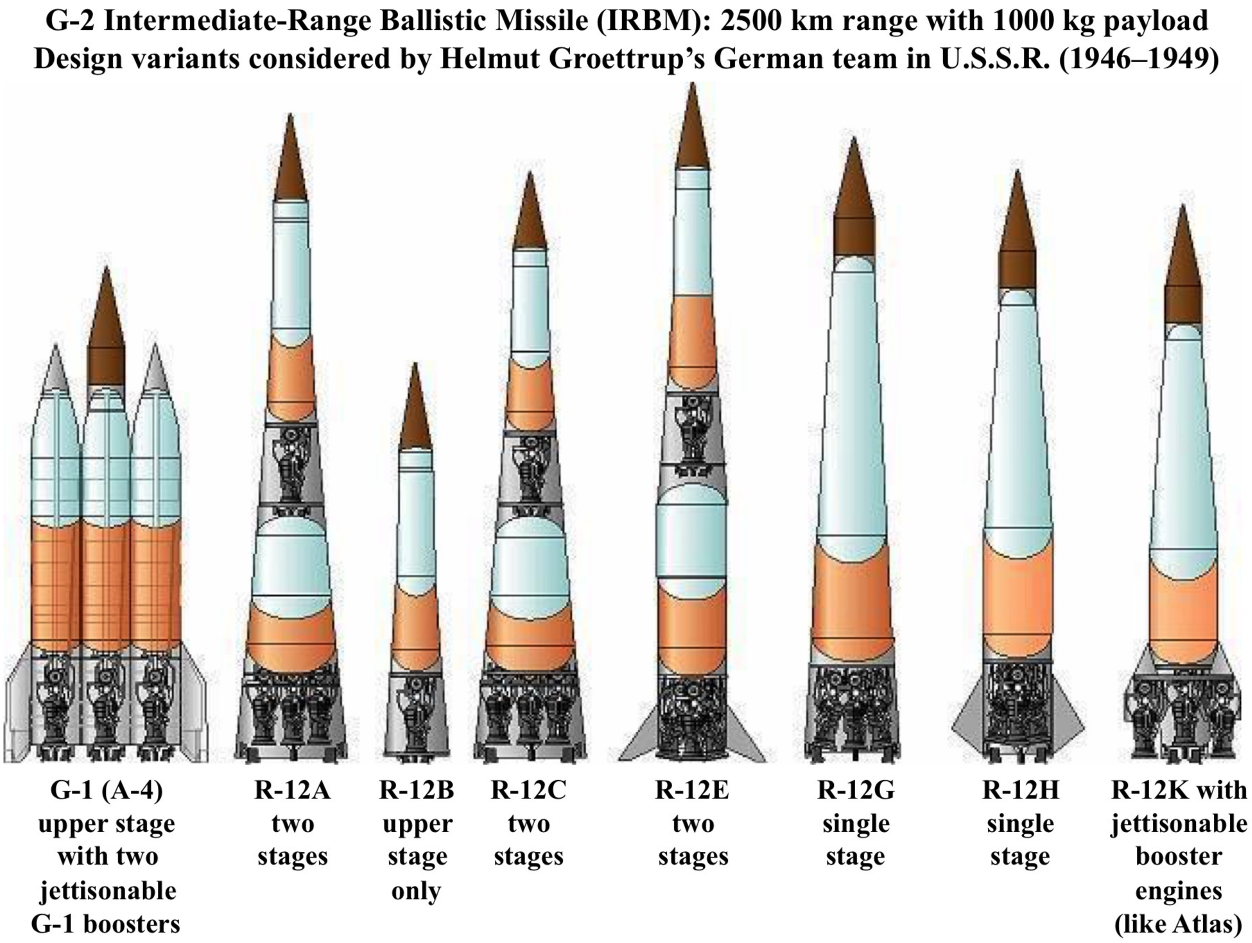
Mark Wade. 2019. G-2 [http://www.astronautix.com/g/g-2.html].

The G-2 design objective was to create the first IRBM—to deliver a 1000 kg payload over a 2500 km range. The missile would use three V-2 derived engines with a total thrust of 100 metric tons. A variety of alternate configurations (R-12A through R-12K) were considered by the German team in Russia. These included parallel and consecutive staging, gimbaled motors, and other innovations. The R-12K was particularly interesting because it represented a concept later used on the US Atlas missile—jettisoning of the two outboard engines at altitude to significantly improve range. [...]

More than ten G-2/R-12 variants were studied in detail to determine the optimum technical solution. All used a common bulkhead between the aft fuel and forward liquid oxygen tank. Two major aerodynamic forms were considered—conical, which was aerodynamic stable regardless of the stage velocity and vehicle center of gravity, and cylindrical stages with fins. The variants studied were as follows:

- G-1 cluster - two G-1's as the first stage flanking a single G-1 as the second stage. Lift-off mass 50 metric tons, lift-off thrust 100 metric tons, total span 6 m, length 15 m.
- R-12A dual sequential stage. Conical form, with 3 G-1 engines in the first stage and a single G-1 engine in the second stage. Length 25.3 m, diameter at the base 4.0 m.
- R-12B short-range V-2 replacement based on second stage of R-12A. 2.4 m base diameter, 16.0 m long.
- R-12C dual stage. A variation of the R-12A with a larger-diameter upper stage. 19.2 m long.
- R-12E dual stage. Cylindrical first stage with aerodynamic stabilizing fins
- R-12G single stage design with conical form
- R-12H single stage with cylindrical form and aerodynamic stabilizing fins
- R-12K with jettisonable booster engines.

The optimum technical solution seemed to be the R-12G single-stage conical design. In comparing the G-2 with Korolev's R-2, the state commission favored the Groettrup design. But the Russian designers convinced the government that the G-2 required innovations beyond the immediate capability of Soviet technology. Korolev's R-2, a modest upgrade of the V-2, was selected for production instead.



G-2 Intermediate-Range Ballistic Missile (IRBM): 2500 km range with 1000 kg payload
Design variants considered by Helmut Groettrup's German team in U.S.S.R. (1946–1949)
G-1 (A-4) upper stage with two jettisonable G-1 boosters
R-12A two stages
R-12B upper stage only
R-12C two stages
R-12E two stages
R-12G single stage
R-12H single stage
R-12K with jettisonable booster engines (like Atlas)

Figure E.174: Some major design variants of the G-2 Intermediate-Range Ballistic Missile (IRBM) that were considered by Helmut Groettrup's team of German engineers in the Soviet Union during the period 1946–1949 [http://www.astronautix.com/g/g-2.html]. Was this project directly based on wartime German work (p. 5560)?

[After the war, German engineers in the United States produced the PGM-19 Jupiter, a rocket with many similarities to the G-2 designs (p. 5501). Jupiter had a diameter of 2.67 m and length of 18 m. It had a range of 2400 km with a 1000 kg payload. Were the Jupiter and G-2 designs unrelated, or the product of postwar spying leading to information transfer between the U.S. and Soviet design teams, or were the U.S.- and Soviet-based German designers using the same wartime German project as their starting point for these postwar rockets?]

Charles P. Bixel. 9 December 1946. Subject: Report No. 45. [NARA RG 319, Entry NM3-85M, Box 40. Folder 925907].

[...] 6. SOVIET RESEARCH IN ROCKET AND ATOMIC WEAPONS

a. Two CZECH Army officers recently returned from a special aeronautical course were enthusiastic about what they saw while attending the school. The officers stated that the USSR is presently engaged in the construction of what they described as the largest rockets in the world. (Evidently the USSR's propaganda campaign has taken effect.) The plants engaged in the construction of these rockets are located in the URALS and are sufficiently dispersed to safeguard them in the event of concentrated bombing attacks. To insure the secrecy of the rocket project, each plant is engaged in the manufacture of only one part. Work on a rocket which these officers described as twice the size of a German V-2 is being conducted with assistance of German scientists. One assembled rocket was seen at CHELYABINSK. The rocket is approximately 4 meters in diameter and approximately 40–45 meters in length. The war-head of the rocket is conically shaped. It differs from the German V-2 in that its tail fins have a much larger surface and are movable. The weapon is of all metal construction and is motivated by a rocket propellant. Since no visible attachment was apparent on the rocket the officers surmised that the engine was built into the fuselage and the rocket vapors, flames, and gases created by the motor were evacuated through the tail section of the rocket. The officers were told at the school that by May 1947 the USSR will have radio or radar controlled rockets capable of extended flights up to 4000 miles.

b. The following dissertation on the intentions and capabilities of the USSR was obtained from a Czechoslovakian official holding a high position in the Czech Government. The source had recently returned from a trip to the USSR. Evaluation is B-3.

The USSR's industrial strength, along with the industrial capabilities of her Satellites, is at present being concentrated in a gigantic armament effort centered around the development of long range rockets with atomic war-heads. This is the major reason why the rebuilding of the devastated areas of the USSR has advanced so slowly and also the reason why the major Ukrainian and Polish armament industries are being put into operation again. The Czechoslovakian official has heard many comments to the effect that the USSR will have the atomic bomb developed not later than June 1947. He knew of no industries or scientific laboratories engaged in atomic research, but claimed high hopes are attached to this new weapon. The Soviets believe that in the event of war between the Western Powers and the so-called Eastern Bloc they will be capable of firing their rockets from Eastern-most Siberia against all of Southern Asia, Australia, and even the Western part of the United States. Alaska will be within easy range of weapons employed at present. The British Islands and the Eastern half of the United States will be reached by rockets from Central Europe.

[...]

(d) MERSEBURG (D-91)

On 3 November 1946 an unknown number of research workers of the LEUNA plant left for the USSR. It could not be determined if they left voluntarily. (USCon F-6)

(e) HALLE (D-92)

200 German families were evacuated to the USSR. Most of the men involved are said to be boilermakers. (USCon F-6)

(f) LEIPZIG (E-21)

The Director of the G. E. Reinhardt factory as well as his three chief technicians have apparently departed for the USSR. (USCon F-6)

(g) MAGDEBURG (Y-60)

On 28 October 1946 one hundred and thirty expert technicians and engineers of the KRUPP munitions factory and the railroad repair shops left MAGDEBURG presumably for the USSR. They were accompanied by their families. According to source all 130 received contracts for five years employment in the USSR. Whether these were signed voluntarily or whether coercion was resorted to could not be determined. (USCon B-2)

[...]

(2) ARNSTADT (J-25)

The "Polte Works" which at one time employed 22,000 people in the production of munitions was dismantled beginning in October 1945. The work was completed in May 1946. (USCon F-6) Source probably referred to "Meta Metallwerk" factory as the Polte Werke of ARNSTADT (J-25) because the Meta Werk, which is reported to have made anti-tank shells during the war, was believed to be associated with the larger Polte arms work of MAGDEBURG. (Y-60).

(3) GREPPIN (E-14)

Dismantling operations on the munitions plant, which once employed 30,000 people, have been proceeding since May 1946. Shipping stickers on crates indicate the machinery is being sent to KIEV. (USCon C-3) [...]

[There is evidence that during the war, the Polte II plant and other facilities around Arnstadt were producing components for large rockets such as those described in this report; see pp. 5344–5351.

There is also evidence that several of the other locations mentioned in this report were doing nuclear-related work during the war (pp. 3670–3677, 4027–4030).

This report is further evidence for how large German industry was during the war, and how greatly dependent postwar Soviet technical development was on all the German experts, information, materials, hardware, and factories that were seized by the Soviet Union at the end of the war.

Many captured German factories and workers were relocated to Chelyabinsk and other places in or near the Ural Mountains in Russia.

Soviet rockets seen only a year after the war were almost certainly based on wartime German designs, and probably had even been built by German industry before the war ended. Most of those were captured or rebuilt A-4 (V-2) rockets, renamed R-1 by the Soviets.

This report from two knowledgeable witnesses described a rocket far larger than the standard 14-meter-long A-4. The two witnesses said the novel rocket was either twice the size of a standard A-4 (thus approximately 28 meters long) or three times the size of an A-4 (40–45 meters). Perhaps those were the sizes of two different large rockets the witnesses saw; if they were the two witnesses' different estimates of the same rocket, they at least indicate that it was much too large to be an A-4.

The smaller estimate, approximately 28 meters, is too large for even a stretched A-4 such as the 18-meter R-2 and the 21-meter R-5 (p. 5574). However, it is an excellent match for the two-stage A-9/A-10 (p. 5271).

The larger estimate, 40–45 meters, is much too large even for an A-9/A-10. Out of the publicly known wartime German rocket designs, this length best matches that of a three-stage A-9/A-10/A-11. There is other evidence that Soviet investigators knew of wartime German work on that project (p. 5570).

The 4000-mile range and the diameter up to 4 meters are also far too large for even an extended A-4. These are two additional pieces of evidence that this rocket was a two-stage A-9/A-10, a three-stage A-9/A-10/A-11, or something similar [perhaps the Bohemian V-3/V-4 (pp. 5516, 5532, 5535, 5544), and/or a rocket related to the G-series (p. 5562)].

The conically shaped warhead sounds quite different than the shape of a conventional inseparable A-4 warhead. It suggests a warhead that was separable for reentry over the target, and likely nuclear given the size and cost of such a rocket.

Thus this report is further evidence that very large rockets designed for intercontinental ranges and likely nuclear payloads were built during the war and captured by the Soviet Union (and possibly other countries as well) after the war.]

Subject: Construction of Radio-guided Rockets at NOVOSIBIRSK. D-152490, CW138175. 12 October 1947. A.I.B. [NARA RG 319, Entry A1-134A, Box 29, Folder ZA 019293 Soviet Guided Missiles, Rockets and V-Weapons Research, Development and Production Vol. 1, Fldr. 1 of 3].

Special Report (translated from Russian)

Subject: Construction of Radio-guided Rockets at NOVOSIBIRSK

1. New radio-guided rockets are being constructed in factory “BOLSHEVIK” at NOVOSIBIRSK. These rockets are similar to the German “V” type but larger in size. This rocket in the shape of a cigar is 16 m long and 2.5 to 3 m in diameter. [...]

2. It is not known how many rockets are being constructed but according to unconfirmed reports only 5 or 6 rockets are constructed for tests and experiments.

3. In charge of the construction is ANSHUKOV an engineer sent from MOSCOW. He is obviously a military officer and he often wears military uniform though without rank insignia. Approx. 10 German specialists arrived from MOSCOW with ANSHUKOV. [...]

[The fact that this larger rocket appeared relatively soon after the war, and as a direct product of German specialists, suggests that it may have been directly based on captured wartime technology, not new designs.

Note that the diameter was much larger than the 1.65 m diameter of the A-4 and closely related rockets.

Based on these dimensions, were these rockets R-12B upper stages (or other design variants) from Helmut Groettrup’s G-2 program?

Alternatively, were these rockets copies of the wartime Bohemian V-3 or V-4 (pp. 5516, 5532, 5535, 5544)?

Or was the Bohemian V-3/V-4 the original wartime German version of the G-2?]

New Soviet Weapons. 10 November 1950 [based on intelligence from 1943–1948]. https://www.cia.gov/readingroom/document/cia-rdp80-00809a000600360061-4

The following is a report of the experiences of a German scientist, Dr H. Tellman, who was taken prisoner by the Russians in 1943 and who worked for them as a scientist until he escaped by airplane. Dr Tellmann now lives in Argentina. [...]

My friend, Professor D. took me along on an inspection trip to Tomsk where the Russians has built an experimental station for V-2 rockets. I met an old acquaintance from Germany, Engineer P., who was in charge of the technical work of the entire installation. At first, the only experiments performed were the same kind which I knew from my work in Germany, but later, during my stay, new designs with much higher power were developed. Work was also carried out in the field of radio guidance of rockets. I saw the launching of several giant rockets whose dimensions considerably exceeded those of the V-2. The measuring devices recorded ceiling altitudes of 210 kilometers in these flights. A new rocket is still in the development stage. It weighs 40 tons and is expected to reach an altitude of more than 400 kilometers. I was also interested in the design of a multistage rocket, whose first stage was to be powered by nuclear energy. [...]

The experimental rockets in the development stage today are nearly powerful enough to fly from the earth to the moon and to leave the earth's gravitational field.

A second trip took me to Kalinin. A large rocket-aircraft-testing station has been built there. The rocket aircraft developed there are based on the design of the German V-1. Essentially, they are nothing but manned rockets. The wings are small and sweptback. The cockpit is hermetically sealed and holds a two-man crew. The Soviets have also succeeded in obtaining the services of most of the important German rocket experts, who have attained very high speeds with their rocket aircraft; in one case, an aircraft equipped with three rocket engines reached a speed of nearly 2,000 kilometers per hour.

During one test flight which I witnessed, the material did not withstand the terrific strain, and the aircraft crashed, killing the German pilot. These aircraft are started from catapults. Fuel consists of a hydrocarbon compound and nitric acid. One of the German test pilots succeeded in reaching an altitude of 25,000 meters with one of these aircraft. The immense power of the engines was demonstrated to me when a rocket aircraft turned over during take-off and exploded. The explosion made a crater of 15 meters in diameter and 3 meters in depth, and the aircraft was torn into tiny fragments. These rocket aircraft are still in the experimental stage. However, the USSR has many types of jet aircraft which are already in service. They were designed and built in a plant near Voronezh by former members of the Messerschmitt firm. [...]

A few days after my return to Moscow, I was taken to Peenemuende. The installation is operating full blast, and the region between Usedom and Greifswald is one single armed camp. There is no trace left of the demolitions carried out in 1945. Over 150 German scientists are working around the clock developing rocket projectiles and rocket-propelled fighter aircraft. I was able to determine that the Russians had obtained all German data for all the versions of the V-2 rocket. Special attention was given to the A-8 version of this rocket, which can fire 6,000 kilometer across the Atlantic with a flight time of 42 minutes.

The tests with guided rockets at Peenemuende made a great impression on me. Rockets were launched from sites in the Leningrad-Kronshtadt area. They landed with almost dead accuracy on the island of Pol. The rockets are launched to an altitude of 12,000 meters, and the propulsion unit of the rocket is cut in at than altitude by radio signal. The rockets then fly in a straight line, controlled by radio and radar signals from picket boats in the Baltic, until a measuring station stops them over the island of Pol and breaks off the flight there. The rockets come down nearly vertically and land near the target. The tests were repeated several times, and the results, in regard to accuracy, were always equally good. I am convinced now that the sensational reports once heard in Germany about rockets over the Baltic were not just imagination, but that rockets from Leningrad sometimes flew as far as Swinemuende, and that some of them supposedly got lost and flew to Sweden.

My work at Peenemuende consisted mostly in trying to persuade the German scientists there to go to work for the War Academy in Moscow. In 1945, the Russians shanghaied the scientists, but stopped this practice in 1948, since they found out that they could not obtain good work from scientists who were in the USSR under duress. During my conversations with my colleagues there I found that the research results obtained at Peenemuende should be a matter of great concern to other countries. The accuracy attained with rockets over the comparatively short range of 1,100 kilometers between Leningrad and Usedom was also attained over a 2,500-kilometer range. These tests were conducted between the Kronshtadt-Leningrad area and the great rocket-testing site at Omsk in Siberia. On the basis of these tests, it could easily be possible for the Russian using rockets launched from the interior of the USSR, to reach any target in Europe or in the US with great accuracy.

I had not given up my plans for escape. I could not bear working under constant political pressure, and I wanted to spare my family from moving to USSR and did not want to expose them to an uncertain fate there.

I was helped by a coincidence. In July 1948 I was at Kharkov, where I had to inspect equipment in the huge power plant. There I met a German engineer named Wintersdorff, a former pilot, who had been shanghaied by the Russians during a visit to Soviet Zone Germany in 1946, and who was plotting an escape by air to Athens where he had a brother-in-law. By luck, a high official of the Ministry of War whom I met at Kharkov invited me to fly back to Moscow with him in his private plane, and agreed to take Wintersdorff, my "assistant" along. During the flight, with the aid of a revolver which Wintersdorff had obtained, we overpowered the official, the pilot, and the radio operator, put parachutes on them, and threw them from the plane. With Wintersdorff at the controls, we flew to Athens, from where I reached Germany.

[Dr. H. Tellmann said he personally witnessed (and in other cases heard of through reliable sources) the testing of several rockets significantly larger and more sophisticated than the A-4/V-2/R-1 in the Soviet Union during the period 1945–1948. The first Soviet-built rocket larger than the A-4/V-2/R-1 was the R-2 or SS-2, which did not fly until October 1950 [Uhl 2001, p. 189]. Thus the advanced rockets that Tellmann described appear to have been captured wartime German rockets.

The A-8 was a modified A-4. For it to travel 6,000 km assumes or implies the existence of the A-10 as a booster stage. Such a long range also indicates that the A-8 would have been equipped with wings like the A-4b or A-9 for a long gliding reentry to the target.]

Boris Chertok. 2005–2012. *Rockets and People.* 4 vols. Washington, DC: U.S. Government Printing Office.
[https://www.nasa.gov/connect/ebooks/rockets_people_vol1_detail.html]

[Vol. 1, p. 242:] The inspection of Peenemünde in May and June 1945 showed that the actual scope of work on rocket technology in Germany was far superior to what we had imagined. We Soviet specialists needed to investigate the entire volume of work that had been done in Germany in the field of rocket technology. But it was just as important to obtain information on the history of these developments and the methods used by German scientists and engineers to solve many difficult problems, such as those involved with the development of long-range guided ballistic missiles.

Before 1945, neither we, the Americans, nor the Brits had been able to develop liquid-propellant rocket engines with a thrust greater than 1.5 metric tons. Those that had been developed were not very reliable, had not gone into series production, and were not used to develop any new type of weapon. By that time, however, the Germans had successfully developed and mastered a liquid-propellant rocket engine with a thrust of up to 27 metric tons—more than eighteen times greater! What is more, they had produced these engines in large-scale series production by the thousands! And the automatic guidance system! It was one thing to fundamentally and theoretically show that for the given level of technology it was possible to control a missile's flight and consequently the engine mode in flight at a range of 300 kilometers; it was a quite another thing to put this into practice and bring the entire system up to a level suitable for acceptance as an operational armament!

[Vol. 1, p. 245:] From 1937 through 1940, the Germans invested more than 550 million Reichsmarks into the construction of the Peenemünde center, an enormous sum for that time. All of Germany's leading electrical and radio engineering firms provided the center with special testing equipment and the latest measurement instruments. Despite our anti-fascist views, we had to credit the directors of the operations, first and foremost Dornberger and von Braun, for the energy and confidence with which they acted.

As a matter of fact, it wasn't just the enthusiasm and organizational capabilities of the Peenemünde directors. They understood perfectly well that the enthusiasm and brilliant capabilities of lone scientists were far from sufficient. What was needed was a clear conception of the scale of operations needed to achieve set objectives, and the determination to create the strongest state-supported scientific-technical, production, and military-testing infrastructure possible. All of this was conceived prior to the war, then refined and implemented during the hostilities under the conditions of Hitler's totalitarian regime, which spared no expense to develop the proposed secret weapon of mass destruction. There was no need to account for the project before parliamentarians. To a significant degree, this contributed to the success of the new endeavor.

On 22 June 1941, Germany attacked the Soviet Union. While certain of a rapid victory on the eastern front, Hitler was troubled by Britain's tenacity. On 20 August 1941, at his "Wolf 's Den" headquarters in East Prussia, he received Colonel Doctor Dornberger, Doctor von Braun, and the lead specialist for the development of missile guidance systems, Doctor Steinhoff. There was no need for the new missile weaponry for the Blitzkrieg against the East, since the Germans would be in Leningrad within a month and Moscow no later than October. Why then such attention to missile specialists? Dornberger and von Braun familiarized Hitler with the current status of their work on the A-4 missile, which had a range of up to 300 kilometers. They also discussed the potential for new missiles that would have intercontinental ranges. As a result of this meeting, Hitler gave the programs at Peenemünde the highest priority.

In autumn 1941, roused by this support from the highest level, the work force at Peenemünde began to speed up the design process for two-stage and perhaps even three-stage A-9, A-10, and A-11 systems. But the basis was to have been the A-4 design.

[Vol. 1, pp. 246–247:] In 1943, there were more than 15,000 dedicated personnel working at Peenemünde. New firing rigs made it possible to conduct firing tests on engines with thrusts from 100 kilograms to 100 metric tons. Peenemünde aerodynamics specialists prided themselves on having the largest wind tunnel in Europe, created over a period of just eighteen months; the largest factory for the production of liquid oxygen; and spacious and excellently equipped design halls. Launching areas for rockets and launch control bunkers were provided during the earliest days of construction on Usedom Island. Correspondingly, the entire path of possible launches along a line running north-to-northeast was equipped with monitoring and observation facilities.

[Vol. 1, p. 254:] In the 1970s, the United States devoted intense attention to developing mobile railroad launchers for the Midgetman missile and, before that, the Minuteman.The USSR also developed intercontinental missile launch variants using railroad rolling stock. But mobile railroad launchers as protection against air attacks had been developed by the Germans as early as 1944 in Peenemünde. The A-4 missile was to have been launched from a simple rack mounted on a railroad flatcar. The mobile launcher consisted of alcohol and liquid oxygen tanks, launch equipment, and the equipment needed to perform pre-launch checks. However, the Germans did not succeed in bringing the mobile launchers to the point of combat-readiness. All of the actual launches were conducted from launch “tables” at fixed positions. The missiles were transported there and set up using a special erector, the so-called *Meillerwagen*.

[Vol. 1, p. 266:] In Peenemünde, there was serious work underway on another large cruise missile. By December 1944, the territory of Germany had been invaded by the Red Army from the east and the Allies from the west. The defeat of the Nazis was inevitable. Nevertheless, the stubborn specialists in Peenemünde launched an A-9 cruise missile under the designation A-4b on 27 December. The launch was unsuccessful. From our vantage point today, the failure can be easily explained—it was simply unavoidable, the knowledge and experience to realize this design did not exist. They started this work with the particular courage that comes with ignorance. The time for the realization of such designs had not yet come, especially since it was already too late to be working on them in Peenemünde. One had only to glance at a map of the military situation.

[Vol. 1, p. 268–269:] Work on the A-9, the winged version of a long-range missile, continued in spite of the catastrophic situation on the Eastern and Western Fronts. On 24 January 1945, a successful launch of the A-4b finally took place. This was the first launch of an experimental long-range missile with wings. [...]

On 14 February 1945, the last A-4 missile was launched from Peenemünde. The Eastern Front of Hitler’s Reich was collapsing. After their decorations were conferred, the Peenemünde directors received no more orders and began to prepare for evacuation on their own initiative. All of the equipment and documentation was packed into cases marked “EW.” The accompanying documents noted that this was the property of an *elektrotechnisches werk* (electrical factory). Convoys of automobiles and special trains carrying specialists, archives, and equipment, headed by Dornberger and von Braun, left Usedom Island on 17 February 1945. They evacuated to the areas of Nordhausen, Bleicherode, Sonderhausen, Lehesten, Witzenhausen, Worbis, and Bad Sachsa. The primary archives with the results of thirteen years of research and work were hidden in the tunnels of Mittelwerk and nearby potassium mines.The main group of Peenemünde directors was sent to the Bavarian Alps. On 4 May, the troops of the Second Byelorussian Army Group entered the area of Peenemünde. On 2 May 1945, the Peenemünde directors went out toward the Americans and surrendered willingly. On the blindingly sunny day of 2 May 1945, when my comrades and I were jubilantly signing our names on the still-smoldering Reichstag walls, the Americans captured some of the most valuable spoils of the war: more than four hundred of the main scientific-technical employees of Peenemünde; documentation and reports; more than one hundred missiles ready to be shipped to the front that had been stored at Mittelwerk and on spur tracks; and combat launchers, along with the military personnel who were trained to operate the missiles!

The next stage in the history of rocket technology had begun. It could rightly be called the Soviet-American stage. German specialists participated in the work of this stage in the USSR and in the United States.

[Vol. 1, pp. 278–279, at the Dora camp:] We began with a Soviet officer who introduced himself as “Shmargun, former prisoner of war, liberated from the camp by the Americans.” [...]

“Now I can show you around the camp. I know some Germans who worked at the factory and didn’t leave. They have agreed to help in investigating everything that was going on there. I can be in contact with ‘that side.’ There were a lot of good guys among the American officers. There are also a lot of Russian girls in town.They were domestic workers and worked on farms.They know the language well, and can serve as interpreters until they are repatriated. I know places where the SS hid the most secret V-2 equipment that the Americans didn’t find. We prisoners knew a lot.”

[...] Shmargun led us to a distant wooden barracks hut, where in a dark corner, after throwing aside a pile of rags, he jubilantly revealed a large spherical object wrapped in blankets. We dragged it out, placed it on a nearby cot, and unwrapped the many layers of blankets. I was stupefied—it was a gyro-stabilized platform of the type that I had seen for the first time in Berlin at the Kreiselgeräte factory. At that time,“civilian” Colonel Viktor Kuznetsov, who was also seeing the instrument the first time, explained its layout to me. How had a gyro-stabilized platform, which still hadn’t become a standard V-2 instrument, ended up in this death camp prisoners’ hut? Shmargun could not give me a clear explanation. According to what he had heard from others, when the camp guards fled, some Germans who were neither guards nor Mittelwerk personnel brought a beautiful case to the barracks, covered it with rags, and quickly fled. By the time that the Americans arrived, the surviving prisoners had discovered the case and opened it; one of them said that it was very secret. They decided to put it away until the Russians arrived. They used the case to pack up various things that they had begun to acquire after liberation, and when they found out that Shmargun was staying to wait for the Russians, they revealed the secret to him and packed everything up in dirty blankets so that the Americans would be less suspicious.

As we could see, the operation went brilliantly. Now Isayev and I were responsible for this priceless windfall. We wrapped it back up in the blankets, since no other container was available, transported it to the division headquarters, and asked them to store it there until we could take it to Moscow. Approximately six months later there was a struggle over the possession of this gyro platform that led to the first rift in the relationship between Viktor Kuznetsov and Nikolay Pilyugin, the friends that I made shortly after the instrument’s discovery.

[Vol. 2, pp. 188–189:] The Germans who developed the guidance system for the A4, and after them our specialists who developed the R-1 and R-2 guidance systems, viewed them as controllable objects possessing the properties of a “solid body,” meaning that when exposed to loads, the missile hull would not deform at all. Such an assumption proved inapplicable for the R-5 missile, which was more than 20 meters long with hull diameter of 1.65 meters, like the R-1. The missile hull bent under the effect of loads from the control fins. The flexural elastic modes of the hull were transferred to the gyroscope bases. The gyroscopes responded naturally to these modes and sent commands to the guidance system, causing the control fins to shift. The loop closed and entered an unexpected self-oscillation mode.

In a joint effort, the OKB-1 and NII-885 dynamics specialists developed measures to limit the effect that this newly discovered phenomenon had on guidance. At one of the meetings that we had on this problem, I reminded Pilyugin about our materials resistance course at the institute. They had taught us that we could use a structure within the limits of its allowable elastic deformation. His comeback was, “We’ll rock the missile with the control fins so much that your Mr. Rough will have to reinforce it with steel longerons.” We introduced various filters into the system, but at NII-885 they continued to bad-mouth the “protection against Mr. Rough.”

Another new curse for the guidance specialists was the effect caused by filling the missile with liquid. The control fins’ vibrations not only bent the missile hull, but also disturbed the liquid oxygen and kerosene in the tanks. The fluctuations of the liquid surface caused additional perturbances. We needed to develop ways to counteract the effect of the filled tanks.

The effect of flexural vibrations and fueled tanks on stability proved very hazardous. The frequency of these vibrations fell within the guidance system’s frequency band. Cooperative research was set up at OKB-1, NII-885, in the scientific departments of NII-88, and the military’s NII-4 to study the new phenomena. Khitrik was in charge of this work at NII-885; Vetrov, Degtyarenko, and Gladkiy headed the project at OKB-1. At NII-4 Georgiy Narimanov made a special study of the effect of the liquid in the missile’s tanks.

Through their combined efforts they developed a guidance theory allowing for the new phenomena. During 1955–56, guidance equipment was developed that was supposed to ensure stabilization over the entire dynamic structure. During this period the R-7 missile was designed, applying the experience derived from the R-5. To this day, missile and guidance system designers have to consider liquidity and elasticity as integrated factors from the very initial design stage.

[Vol. 2, p. 272:] Based on our own many years of experience, as well as that of the Germans, we knew that no orders and entreaties would guarantee the reliability of all the electrical equipment, the onboard cable network, and control instruments, since any single failure such as a broken wire, loss of contact in a plug and socket connector, or random short circuit would cause a missile to crash. Furthermore, the single-stage R-5 was a statically unstable flying vehicle. Unlike the R-1 and R-2, it had no stabilizers. Only after a thorough analysis and study of the behavior of this long missile in flight did we begin to understand the hazard of disregarding the elastic vibrations of the entire structure and the effect of liquid-fueled tanks. The guidance system also needed to have a significantly greater margin of resistance and controllability in terms of its dynamic characteristics than its predecessors.

[Figure E.175 presents the first three major types of Soviet ballistic missiles (see also p. 5797):

- The SS-1 or R-1 Scunner was basically just an A-4/V-2 rocket (14 meters long) that was manufactured by Germans under Soviet control and used 1950–1953.

- The SS-2 or R-2 Sibling was a longer, upgraded A-4 (18 meters long) that was in service 1953–1956. Not only was it produced by German engineers, but it appears to have been copied from 18-meter extended A-4 rockets that were secretly developed and tested in Germany during the war (p. 5794).

- The SS-3 or R-5M Shyster, also shown in Fig. 9.180, was an even longer upgraded A-4 (21 meters long) that was in service 1956–1967. It was again created by German engineers, also apparently based on wartime work (p. 5794). In fact, with its 1200 km range, capable of delivering a nuclear warhead to anywhere in the United Kingdom from dedicated launch sites near Peenemünde, the SS-3 appears to have been the very embodiment of wartime German plans (p. 5575).

Later Soviet rockets, including those still used by Russia today, were also the product of German-speaking engineers working in the Soviet Union (pp. 1879–1881).]

Niklas Reinke. 2007. ***The History of German Space Policy: Ideas, Influences, and Interdependence 1923–2002.*** **Paris: Beauchesne. pp. 36–37:**

Together with thirty or so leading scientists, propulsion expert Walter Riedel (1902–1968) arrived in Britain, where there had been practically no experiments with liquid-propellant rockets before 1945. Since the British lacked the financial resources for a large-scale rocket programme, the scientists from Peenemünde were unable to develop their work to the full. They are nevertheless credited with work on BLUE STREAK, the military rocket that was to serve as the first stage of the European launcher programme in the 1960s, and on BLACK ARROW, a more powerful rocket that placed the first British satellite, PROSPERO, in polar orbit on 28 October 1971.

Unlike the British, the French already had some experience in the field of [rocket] propulsion. After the war, in conjunction with seventy former members of the Peenemünde team, mostly [rocket] propulsion experts, they developed a small liquid-propellant rocket, VERONIQUE, at their new ballistics and aerodynamics research facility, the Laboratoire de recherches balistiques et aérodynamiques (LRBA) in Vernon. From 1954, VERONIQUE was also used very successfully in a series of German tests. While most of the German experts left France after 1956, the remaining few were involved in the construction of the propulsion unit for the DIAMANT launcher, whose first stage was derived from the V2, and of ARIANE. Another 50 or so experts headed by the German propulsion specialist Sänger worked for the French aviation ministry on the development of rocket- and jet-propelled aircraft.

Most of the Peenemünde technicians were transferred to the Soviet Union[...] While the Americans were able to draw the most important specialists to their side, the production plant at Nordhausen, which was almost intact, remained in the Soviet occupation zone. The old Mittelwerk plant was soon put back into operation, and by the end of 1945 the Soviets had already tested their first V2. In the night of 21 to 22 October 1946 the Red Army deported at least 3,500 German specialized personnel and their families to the USSR in 92 trains. The plant itself had been dismantled by the spring of 1948, and most of it was later blown up.

Charlie Hall. 2019a. ***British Exploitation of German Science and Technology.*** **New York: Routledge. p. 232:**

In the defence sphere, the areas which benefitted most were aeronautics and guided projectile development, many of the German experts in which had been recruited through Operation Surgeon. German expertise contributed to the design of the English Electric Lightning supersonic jet fighter, the Black Knight missile, and, much later, Concorde—all of which remain peaks of post-war British technological production. It really is little wonder that, in August 1948, the Defence Research Policy Committee reported that ‘many of our German scientists are settling down and becoming of real value to our long term research programmes’. This assessment was certainly borne out by the facts—Blue Steel, the principal British nuclear missile between 1963 and 1968, was based on earlier German designs, while Concorde did not come into service until 1976. One of the main reasons why the monetary value of German contributions is so incalculable is because there is no way of knowing how long it would have taken, nor how much it would have cost, for Britain to achieve these developments without German involvement.

Vincent Nouzille and Olivier Huwart. 1999. Comment la France a recruté des savants de Hitler. *L'Express* no. 2498 (20 May), p. 122. https://www.lexpress.fr/informations/comment-la-france-a-recrute-des-savants-de-hitler_633743.html

[Just as they did in the United States, United Kingdom, and Soviet Union, German-speaking scientists, materials, and information had an enormous impact on postwar programs in France. Investigative journalists Vincent Nouzille and Olivier Huwart researched unclassified French government records and described the recruitment and ultimate technological impact of over 1000 German and Austrian scientists and engineers in France after the war, especially with regard to missiles and other aerospace technologies.]

"Regardez comme c'est beau!" De la fenêtre d'un salon campagnard qui surplombe les boucles de la Seine, en aval de Vernon, un petit homme de 86 ans, à l'allure fière et au regard pétillant, montre une immense volute de fumée blanche qui s'élève dans le ciel pâle, au-dessus de la ligne boisée des crêtes. "Ils font encore un essai pour Ariane 5", murmure le vieillard, avant de se rasseoir devant une grande table de chêne, au côté de son épouse, pour feuilleter un classeur de documents jaunis par le temps. "J'ai bien connu tout cela, j'ai bien connu tout cela...", répète-t-il, d'une voix nostalgique mâtinée d'un fort accent germanique. L'homme s'appelle Otto Kraehe. Il est allemand. Pas n'importe quel Allemand.

"Look how beautiful it is!" From the window of a country lounge overlooking the loops of the Seine below Vernon, an 86-year-old man with a proud look and sparkling eyes shows a huge scroll of white smoke rising into the pale sky above the wooded line of the ridges. "They are still testing for Ariane 5," whispered the old man, before sitting down in front of a large oak table next to his wife to leaf through a binder of documents yellowed by time. "I have known all this, I have known all this...," he repeats, in a nostalgic voice with a strong Germanic accent. The man's name is Otto Kraehe. He is German. Not just any German.

Entre 1935 et 1945, cet ingénieur berlinois a participé, sur la base secrète de Peenemünde, en mer Baltique, aux recherches de Wernher von Braun, le concepteur des fusées V2, ces fusées que Hitler lâcha en masse sur Londres et Anvers à la fin de la guerre. Fait prisonnier en 1945 par les Américains, von Braun, scientifique opportuniste et officier SS, devint aux Etats-Unis le père des programmes spatiaux de la Nasa de l'ère Kennedy. "Il rêvait depuis toujours d'envoyer une fusée sur la Lune. Il a réussi", ironise Kraehe. 120 anciens de Peenemünde ont suivi leur patron outre-Atlantique. Plus de 200 ont été embarqués de force par les Soviétiques. D'autres sont restés en Europe. Comme Kraehe. "Von Braun m'avait promis qu'il me ferait venir dès que possible", raconte à L'Express le retraité vernonnais. "Mais, en 1945, j'étais au chômage. Je savais que nous ne pourrions plus mener nos recherches en Allemagne. J'ai appris que la France cherchait des ingénieurs pour reconstituer des V 2. Les conditions étaient bonnes. Alors, j'ai signé un contrat avec le ministère de l'Armement. J'ai commencé à Puteaux, puis j'ai rejoint une soixantaine d'Allemands au Laboratoire de recherches balistiques et aérodynamiques [LRBA], créé à Vernon en mai 1946. Au début, les gens du coin se demandaient ce que nous bricolions dans nos baraques cachées dans la forêt. Nos tests de fusées faisaient un bruit monstre et dégageaient d'épaisses fumées. Et puis tout le monde s'est habitué à notre présence. J'ai été le premier à me marier avec une jeune femme de la région, en 1950. Je suis reparti en Allemagne en 1958, avant de revenir en France en 1963 et de m'installer ici pour ma retraite. Mes collègues restés au LRBA ont mis au point la fusée Véronique et le moteur Viking des fusées Ariane."

Between 1935 and 1945, this Berlin engineer participated, on the secret base of Peenemünde in the Baltic Sea, in the research of Wernher von Braun, the designer of the V2 rockets, those rockets that Hitler dropped en masse on London and Antwerp at the end of the war. Taken prisoner in 1945 by the Americans, von Braun, an opportunist scientist and SS officer, became the father of NASA's space programs in the United States during the Kennedy era. "He had always dreamed of sending a rocket to the moon. He succeeded," Kraehe says ironically. 120 Peenemünde alumni followed their boss across the Atlantic. More than 200 were forcibly taken by the Soviets. Others stayed in Europe. Like Kraehe. "Von Braun promised me that he would bring me as soon as possible," says the retired Vernoner to L'Express. "But in 1945, I was unemployed. I knew we would no longer be able to conduct our research in Germany. I learned that France was looking for engineers to reconstitute V2s. The conditions were good. So I signed a contract with the Ministry of Armament. I started in Puteaux, then joined about sixty Germans at the Laboratory for Ballistic and Aerodynamic Research [LRBA], created in Vernon in May 1946. At first, locals wondered what we were doing in our huts hidden in the forest. Our rocket tests made a monster noise and emitted thick fumes. And then everyone got used to our presence. I was the first to marry a young woman from the region in 1950. I went back to Germany in 1958, before returning to France in 1963 and settling here for my retirement. My colleagues at the LRBA developed the Véronique rocket and the Viking engine for the Ariane rockets."

Un témoignage précieux. Otto Kraehe est, avec Helmut Habermann [...], l'un des rares survivants allemands présents en France de cette épopée. Leur collègue Heinz Bringer, le père du moteur Viking, est décédé près de Vernon le 2 janvier dernier, à l'âge de 90 ans. Leur aventure a longtemps été tenue secrète. Et pour cause: les contrats de travail signés avec le ministère de l'Armement leur interdisaient de parler à quiconque de leurs travaux. Ils risquaient la peine capitale! "Certains croient encore que la France est partie de zéro dans la conquête spatiale. Ce fut longtemps la thèse officielle. Mais c'est faux", raconte Roland Hautefeuille, un passionné d'histoire, dont les travaux sur les V 2 font autorité.

En vérité, sans l'apport de ces Allemands de Peenemünde, le LRBA et la Société européenne de propulsion (créée en 1971 à Vernon pour les moteurs d'Ariane) n'auraient jamais remporté tant de succès. Il n'y aurait pas eu, dès novembre 1965, de roulement de tambour gaullien sur la "troisième puissance spatiale du monde" après l'envol de la fusée Diamant au-dessus du pas de tir d'Hammaguir, où s'activaient quelques-uns de ces experts. Pas de décollage du lanceur européen Ariane de la base de Kourou, en 1979. Pas de fumée blanche sur les rives de la Seine... [...]

A precious testimony. Otto Kraehe is, with Helmut Habermann [...], one of the few German survivors present in France from this epic. Their colleague Heinz Bringer, the father of the Viking engine, died near Vernon on January 2, at the age of 90. Their adventure has long been kept secret. And for good reason: the employment contracts signed with the Ministry of Armament prohibited them from talking to anyone about their work. They were facing capital punishment! "Some still believe that France started from scratch in the space conquest. This was for a long time the official thesis. But that's not true," says Roland Hautefeuille, a history buff, whose work on V2 is authoritative.

In fact, without the contribution of these Germans from Peenemünde, the LRBA and the European Propulsion Company (created in 1971 in Vernon for Ariane engines) would never have been so successful. As early as November 1965, there was no Gaulish drum roll on the "third largest space power in the world" after the Diamant rocket took off over the Hammaguir firing point, where some of these experts were active. No take-off of the European Ariane launcher from the Kourou base in 1979. No white smoke on the banks of the Seine.... [...]

Ces remarques ne sont pas infondées. L'installation dans l'Hexagone des savants d'outre-Rhin ne va pas de soi. Comme l'accord interallié d'avril 1946 interdit toute activité militaire en Allemagne, les grosses équipes, rassemblées d'abord dans la zone française d'occupation, doivent déménager. Une vingtaine d'Allemands, dirigés par Eugen Sänger - un savant hitlérien qui rêvait de fusées rebondissant sur la stratosphère pour bombarder les Etats-Unis! - rejoignent l'arsenal aéronautique de Puteaux en juillet 1946. Ils cohabitent avec l'équipe des "engins spéciaux" d'Emile Stauff, le futur père des missiles tactiques français. Certains s'ignorent: "J'étais assis en face d'un Allemand", racontera l'ingénieur Malaval. "Après m'avoir dit bonjour, il s'asseyait et ne me disait plus un mot. A midi, la moitié de [son paquet de] gris était fumée et la moitié du papier vierge, remplie de calculs. Mais je n'ai jamais rien compris à ce qu'il faisait." Tous ne sont pas aussi renfermés. "C'était des gens urbains et agréables", confiera Emile Stauff. "Ils nous ont été extrêmement utiles." Sans copier les armes allemandes, l'arsenal s'en inspire pour concocter des missiles air-air ou le missile antichar SS 10, qui se vendra à 30 000 exemplaires dans le monde. C'est à partir de ces succès que l'Aerospatiale développera plus tard ses Exocet, Milan, Hot, Roland. Notamment en coopération avec l'Allemagne! Nostalgique et aigri, Eugen Sänger retournera, quant à lui, à Stuttgart en 1954, avant de mettre ses connaissances au service de l'Egyptien Nasser, avec d'autres experts nazis des missiles, dont Wolgang Piltz, ancien de Peenemünde passé par le LRBA de Vernon.

These remarks are not unfounded. The installation in France of scientists from across the Rhine is not self-evident. As the Allied Agreement of April 1946 prohibited all military activity in Germany, the large teams, first gathered in the French occupation zone, had to move. About twenty Germans, led by Eugen Sänger–a Hitlerian scientist who dreamed of rockets bouncing off the stratosphere to bomb the United States!—joined the aeronautical arsenal of Puteaux in July 1946. They cohabit with the "special devices" team of Emile Stauff, the future father of French tactical missiles. Some people ignore each other: "I was sitting in front of a German," said engineer Malaval. "After he said hello, he sat down and didn't say a word to me. At noon, half of [his pack of] grey was smoked and half of the blank paper, filled with calculations. But I never understood anything about what he was doing." Not all of them are so withdrawn. "They were urbane and pleasant people," said Emile Stauff. "They have been extremely helpful." Without copying German weapons, the arsenal was inspired by them to design air-to-air missiles or the SS 10 anti-tank missile, which sold 30,000 units worldwide. It is from these successes that Aerospatiale would later develop its Exocet, Milan, Hot, Roland. Especially in cooperation with Germany! Nostalgic and bitter, Eugen Sänger returned to Stuttgart in 1954, before putting his knowledge at the service of the Egyptian Nasser, along with other Nazi missile experts, including Wolgang Piltz, a former Peenemünde veteran who passed through the LRBA in Vernon.

La plupart des ingénieurs des V 2 recrutés par la France ont, en effet, émigré de la région d'Emmendingen à la petite cité de l'Eure à partir de mars 1947. Une ancienne usine Brandt, isolée dans la forêt, a été aménagée. La colonie allemande vit à deux pas, dans ce qu'ils appellent le Buschdorf, le village de brousse. "En général, l'accueil de la population a été correct, racontera Heinz Bringer au journal de l'Eure Le Démocrate, en 1990. Mais il y avait, à Vernonnet, une bande de jeunes gens hostiles. Une fois, un de mes collègues a été agressé pendant le bal du 14-Juillet."

Ce climat de défiance se dissipe au fil des mois. "Nous nous sommes vite intégrés et la coopération est devenue fructueuse avec les ingénieurs français qui nous ont rejoints", se souvient Helmut Habermann. Après l'abandon en 1948 des coûteuses recherches sur les V 2, le noyau allemand du LRBA—réduit à une trentaine d'ingénieurs—planche sur la fusée-sonde Véronique, le missile sol-air Parca, le radar Aquitaine, le lanceur Diamant. Puis Heinz Bringer, intégré avec une équipe "propulsion" à la SEP en 1971, mettra au point les moteurs Viking qui équiperont les fusées Ariane. Naturalisé sous le nom d'Henri Bringer, ce dernier recevra des "récompenses forfaitaires" au titre de ses inventions, qui demeurent propriété de l'Etat français.

En 1978, le ministère de la Défense lui octroiera notamment un bonus de 56 000 F pour sa "turbo-pompe". Modeste cadeau à l'un des pères d'Ariane! "Je suis heureux d'avoir travaillé pour la France et la recherche spatiale jusqu'à ma retraite, en 1982", explique Helmut Habermann, devenu à la SEP le précurseur des paliers magnétiques.

Most of the V2 engineers recruited by France emigrated from the Emmendingen region to the small town of Eure in March 1947. A former Brandt factory, isolated in the forest, has been built. The German colony lives a stone's throw away, in what they call the Buschdorf, the bush village. "In general, the reception of the population has been correct," Heinz Bringer told the Eure newspaper Le Démocrate in 1990. "But there was a gang of hostile young people in Vernonnet. One time, one of my colleagues was attacked during the ball on July 14th."

This climate of mistrust dissipated over the months. "We quickly integrated and the cooperation became fruitful with the French engineers who joined us," recalls Helmut Habermann. After the abandonment in 1948 of costly research on V2s, the German nucleus of the LRBA—reduced to about thirty engineers—was working on the Véronique sounding rocket, the Parca ground-to-air missile, the Aquitaine radar and the Diamant launcher. Then Heinz Bringer, integrated with a "propulsion" team at SEP in 1971, developed the Viking engines that will power Ariane rockets. Naturalized under the name Henri Bringer, the latter will receive "fixed rewards" for his inventions, which remain the property of the French State.

In 1978, the Ministry of Defence granted him a bonus of 56,000 francs for his "turbo-pump." A modest gift to one of Ariane's fathers! "I am happy to have worked for France and space research until I retired in 1982," says Helmut Habermann, who became the creator of magnetic bearings at SEP.

Mark Wade. 2019. http://www.astronautix.com/s/superv-2.html

French intermediate range ballistic missile. Developed version of German A9 studied by the German team in France in 1946-1948. Cancelled as too ambitious, but led to the Veronique of the 1950's, the Diamant of the 1960's, and the Ariane space booster of 1979–2003.

AKA: Project 4212.
Status: Cancelled 1947.
Payload: 1,000 kg (2,200 lb).
Thrust: 392.00 kN (88,125 lbf).
Gross mass: 20,000 kg (44,000 lb).
Height: 14.50 m (47.50 ft).
Diameter: 1.65 m (5.41 ft).
Span: 3.60 m (11.80 ft).
Location: Vernon.

Jürgen Michels. 1997. *Peenemünde und seine Erben in Ost und West: Entwicklung und Weg deutscher Geheimwaffen.* Bonn: Bernard & Graefe. pp. 277–278.

Projekt 4212 / "Super V 2"

Bereits ab 1946 leistete Heinz Bringer in Riegel Vorarbeit für ein Projekt, das das LRBA zu einer Boden-Boden-Rakete ausbaute. Äußere Form und Maße sollten dem Aggregat 4 entsprechen, aber mit einem stärkeren Triebwerk von 40 t Schub. Drei grundlegende Ausführungen untersuchte man mit folgenden Parametern:

Project 4212 / "Super V-2"

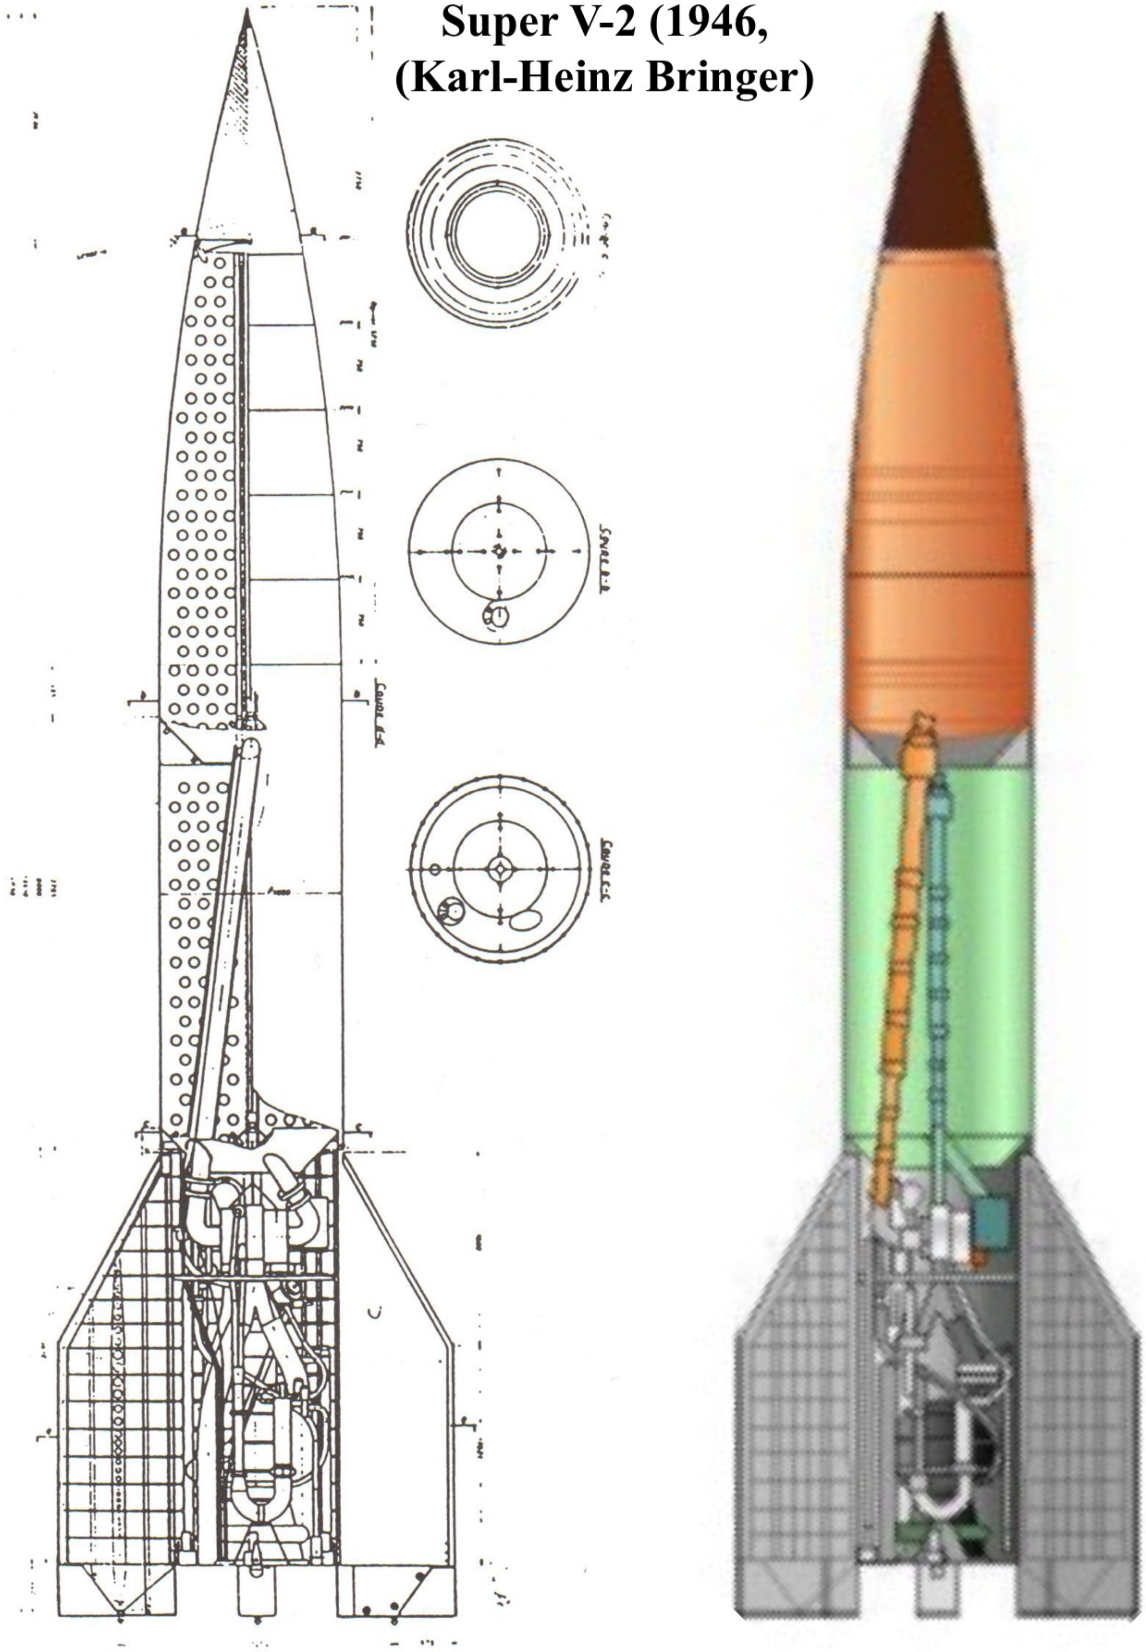
As early as 1946, Heinz Bringer worked in Riegel on the preparatory work for a project which the LRBA developed into a ground-to-ground rocket. The external shape and dimensions were to correspond to those of Aggregate-4, but with a more powerful engine of 40 ton thrust. Three basic designs were investigated with the following parameters:

Type	Payload in kg	Range in km	Propellant delivery	Propellant type
R1	1000	1500	Gas generator	Nitric acid Kerosene
R2	1000	1400	Turbopump	Oxygen Kerosene
R2S	1000	1800	Turbopump	Nitric acid Kerosene
R2S	500	2250	Turbopump	Nitric acid Kerosene

Eine vierte Ausführung wurde später noch hinzugefügt. Es handelt sich um eine semi-ballistische Version mit der Bezeichnung R2M, die zwei Starthilfsraketen besaß und eine Tonne Sprengstoff auf 3600 km bringen sollte. Das Studium am Projekt 4212 erbrachte keine Ausführung eines flugfähigen Gerätes. Aufgrund des geringen Interesses, das die offiziellen französischen Stellen anfänglich an den Tag legten, führte es zur Aufgabe des Projektes im Jahre 1948. Jedoch die theoretischen Studien und die Herstellung von Prototypen und deren Baugruppen wurden in ihrer Gesamtheit durchgeführt. So wurde einige Tage vor Neujahr 1947 der Gasgenerator für den 40 t-Motor auf den Versuchsstation erfolgreich getestet. Im Rahmen dieser Studien wurde erkannt, daß Salpetersäure als Brennstoff Vorteile hinsichtlich der Lagerung, des Transports, der Bedienbarkeit und seines Antriebsvermögens bietet. Während dieser Entwicklungsetappe wurden erste unfangreiche Investitionen des LRBA hinsichtlich der Prüfstände getätigt.

A fourth version was added later. It was a semi-ballistic version called R2M, which had two booster rockets and was supposed to carry a ton of explosives 3600 km. The study at the project 4212 did not yield any execution of an airworthy device. Due to the lack of interest initially shown by the official French authorities, it led to the abandonment of the project in 1948. However, the theoretical studies and the production of prototypes and their assemblies were carried out in their entirety. A few days before New Year's Day 1947, the gas generator for the 40 ton engine was successfully tested on the test stand. During these studies it was recognized that nitric acid as a propellant offers advantages in terms of storage, transport, operability and propulsion. During this development stage, the LRBA made the first major investments in the test benches.

[To what extent was Karl-Heinz Bringer's 1946 Super V-2 design based on wartime German designs or even wartime hardware? Note that the first version of the Super V-2 had many similarities to Heinz Stoelzel's 1945 design (p. 5387): nitric acid for the oxidizer, a long-chain hydrocarbon for the fuel, larger amounts of propellant than in the standard V-2, and pressurized gas for the propellant feed (highly unusual, at least for the publicly known German rockets, which generally used turbopumps!).]



Super V-2 (1946,
(Karl-Heinz Bringer)

[One should read all of this long article; I have only quoted a few parts here. See also pp. 4611–4624.]

Die OTRAG

Öffentliches Aufsehen erregte in den siebziger und Anfang der achtziger Jahren der Versuch der in der Bundesrepublik ansässigen Privatfirma Orbital Transport- und Raketen-AG (OTRAG), das Know-how der Peenemünder Raketenspezialisten für die Entwicklung von Raketen großer Reichweite zu nutzen. Die Authorisierung durch einen anderen souveränen Staat war notwendig, da die Bundesrepublik durch die WEU-Bestimmungen eingeschränkt war und nach dem Weltraumvertrag von 1967 die Nutzung durch Privatfirmen ausgeschlossen ist. Offizielles Ziel von OTRAG war die Entwicklung und Vermarktung von Raketen für den billigen Zugang in die kommerziell wichtige geostationäre Umlaufbahn.

Dies sollte mit einer modularen Trägerrakete erfolgen, die von dem deutschen Raketeningenieur Lutz Kayser entwickelt wurde. Kayser, gleichzeitig Gründer und Geschäftsführer der OTRAG seit 1974, hatte bereits als Jugendlicher Kontakt zu den Peenemünder Raketenbauern. Er trat 1954 der GfW in Stuttgart bei und studierte bei Wolfgang Pilz, Eugen Sänger und Armin Dadieu. Dadieu war im Dritten Reich für die Uran-Lagerstättenforschung in der Steiermark verantwortlich, arbeitete später für die OTRAG sowie als Gutachter der Bundesregierung in Sachen OTRAG und gehörte den Ausschüssen für Transportsysteme des Appollo-Nachfolgeprogramms und für die Trägerrakete EUROPA-III an. Kurt H. Debus, ehemals Leiter der Peenemünder V2-Raketenversuche und bis 1975 Leiter des US-Raumfahrtzentrums Cap Canaveral, war seit 1975 Aufsichtsratsvorsitzender der OTRAG. Der ehemalige V2-Triebwerksspezialist in Peenemünde und spätere Leiter der Chrysler Space Division der NASA, Richard Gombertz, wurde Technischer Leiter der OTRAG. [...]

OTRAG

In the 1970s and early 1980s, the attempt by the private company Orbital Transport- und Raketen-AG (OTRAG), based in the Federal Republic of Germany, to use the expertise of the Peenemünde rocket specialists for the development of long-range rockets caused a public stir. Authorization by another sovereign state was necessary, as the Federal Republic of Germany was restricted by WEU regulations and the 1967 Outer Space Treaty precludes use by private companies. OTRAG's official aim was to develop and market rockets for cheap access to the commercially important geostationary orbit.

This was to be achieved with a modular launch vehicle developed by the German rocket engineer Lutz Kayser. Kayser, founder and managing director of OTRAG since 1974, had already been in contact with the Peenemünde rocket builders as a teenager. He joined the GfW in Stuttgart in 1954 and studied under Wolfgang Pilz, Eugen Sänger and Armin Dadieu. Dadieu was responsible for uranium deposit research in Styria during the Third Reich, later worked for OTRAG and as an expert for the German government on OTRAG issues and was a member of the committees for transport systems for the Appollo successor program and for the EUROPA-III launch vehicle. Kurt H. Debus, former head of the Peenemünde V2 rocket tests and head of the US space center Cap Canaveral until 1975, had been Chairman of the Supervisory Board of OTRAG since 1975. The former V2 engine specialist in Peenemünde and later head of NASA's Chrysler Space Division, Richard Gombertz, became Technical Director of OTRAG. [...]

Ägypten

Ägypten hatte bereits in den sechziger Jahren unter Führung von Gamal Abdel Nasser internationales Aufsehen mit einem Raketenprogramm erregt, an dem maßgeblich deutsche Wissenschafter und Ingenieure beteiligt waren.75 Schon nach dem Rückschlag der Vereinigten Arabischen Armeen im Palästina-Krieg 1948-1949 war das Bedürfnis nach verbesserten Waffen aufgekommen (wie im Deutschland der frühen dreißiger Jahre). 1951 wurde ein kleines Team unter Leitung des deutschen Rüstungsexperten Wilhelm Voss beauftragt, eine kleinkalibrige Rakete zu entwickeln und eine moderne Rüstungsindustrie aufzubauen. 1953 wurde das Programm in die Erforschung von Flüssigkeitsantrieben unter Leitung des deutschen Raketen-Ingenieurs Rolf Engel umgewandelt, wegen finanzieller Probleme jedoch 1956 gestrichen.

Nassers Peenemünde

Da sich Ende der fünfziger Jahre einige deutsche Raketenexperten unterbeschäftigt fühlten, ergriff Nasser die Gelegenheit, sie für seine Zwecke zu erwerben. Nach dem Start einer israelischen Höhenforschungsrakete im Juli 1961 wurde die Entwicklung beschleunigt. Da die NASA eine entsprechende Unterstützung Ägyptens abgelehnt hatte, wurde Eugen Sänger beauftragt, Veteranen aus Peenemünde zu rekrutieren. Unter den etwa zehn Wissenschaftlern befanden sich der Triebwerksspezialist Wolfgang Pilz, der schon in den frühen fünfziger Jahren in Kairo und danach in Frankreich an Raketenprogrammen gearbeitet hatte, sowie die Steuerungsexperten Paul Jens-Görcke und Hans Kleinwächter, der ein Elektronikuntenehmen in Bayern besaß (Frank (1967)). Zu diesem Zweck gründeten Sänger, Pilz und Görcke 1960 die Internationale Raketen (INTRA) Handelsgesellschaft mbH, die u.a. von Messerschmidt, Bölkow und Heinkel hergestellte Raketenteile nach Ägypten exportierte. Beteiligt waren die Schweizer Firma Patvag, die Oerlikon-Tochter Contraves und die spanische Messerschmidt-Niederlassung MECO (Geissler (1978)).

Egypt

Egypt had already attracted international attention in the 1960s under the leadership of Gamal Abdel Nasser with a missile program in which German scientists and engineers were heavily involved.75 The need for improved weapons had already arisen after the setback of the United Arab Armies in the 1948-1949 Palestine War (as in Germany in the early 1930s). In 1951, a small team led by the German armaments expert Wilhelm Voss was commissioned to develop a small-caliber missile and establish a modern armaments industry. In 1953, the program was transformed into research into liquid propulsion under the direction of German rocket engineer Rolf Engel, but was cancelled in 1956 due to financial problems.

Nasser's Peenemünde

As some German rocket experts felt underemployed at the end of the 1950s, Nasser seized the opportunity to acquire them for his own purposes. After the launch of an Israeli sounding rocket in July 1961, development was accelerated. As NASA had refused Egyptian support, Eugen Sänger was commissioned to recruit veterans from Peenemünde. The ten or so scientists included engine specialist Wolfgang Pilz, who had already worked on rocket programs in Cairo in the early 1950s and then in France, as well as control experts Paul Jens-Görcke and Hans Kleinwächter, who owned an electronics company in Bavaria (Frank (1967)). To this end, Sänger, Pilz and Görcke founded Internationale Raketen (INTRA) Handelsgesellschaft mbH in 1960, which exported rocket parts manufactured by Messerschmidt, Bölkow and Heinkel, among others, to Egypt. The Swiss company Patvag, the Oerlikon subsidiary Contraves and the Spanish Messerschmidt subsidiary MECO were also involved (Geissler (1978)).

Etwa 250 Techniker aus der Bundesrepublik, Spanien, Österreich und der Schweiz wurden für den Aufbau der Raketenproduktion in der Militärfabrik 333 bei Heliopolis südlich von Kairo benötigt, insgesamt waren dort zeitweise bis zu 4000 Menschen beschäftigt. Allein Sänger und drei seiner Kollegen sollen pro Jahr den für damalige Verhältnisse erklecklichen Risikozuschlag von 450.000 Dollar pro Jahr erhalten haben.76

Nasser mußte für sein Raketenprogramm enorme Summen aufbringen und erhielt als Gegenleistung schon 1962 die ersten Raketen, die er stolz auf einer Parade im Juli des Jahres präsentieren konnte: die etwa 350 km weit reichende AL ZAFIR und die rund 600 km weit reichende AL-KAHIR. Die AL ZAFIR war mehr als 5 m lang und trug einen 500 kg schweren konventionellen, hochexplosiven Gefechtskopf. Die AL-KAHIR war 12 m lang und konnte einen 750 kg Gefechtskopf transportieren. Beide hatten nur eine Stufe und wurden von Kerosin und Salpetersäure angetrieben. Ein Jahr später konnte Nasser einen weiteren Raketentyp vorführen, die zweistufige AL-ARED, die zwei Tonnen Sprengstoff mehr als 1000 km weit tragen sollte und angeblich sogar 1 Tonne in eine niedrige Umlaufbahn. Eine noch größere Rakete war geplant, die dreistufige AL-NEGMA, die die beiden Stufen der AL-ARED verwenden sollte und für die dritte Stufe Ergebnisse der ELDO-Forschungen.

Die technischen Probleme waren allerdings enorm, besonders mit Lenkung und Flugkontrolle, so daß in der Anfangsphase des Fluges die Rakete über Draht gesteuert werden mußte. Daneben geriet das Raketenprojekt auch unter politischen Beschuß, v.a. durch die israelische Regierung, die mit diplomatischen Mitteln und unter Anwendung von Gewalt (Entführung, Bombenanschläge) gegen die Mitglieder des Raketenteams versuchte, das Programm zu beenden. Der Vorwurf der israelischen Außenministerin Golda Meir, Ägypten entwickle Massenvernichtungswaffen für seine Raketen, ließ die deutsche Bundesregierung unter Ludwig Erhard im Dezember 1963 den Rückzug der Raketenexperten einleiten, unter Inkaufnahme des diplomatischen Bruchs mit Ägypten. Eugen Sänger und Armin Dadieu hatten sich auf Bonner Druck bereits vorher verabschiedet.

Around 250 technicians from Germany, Spain, Austria and Switzerland were needed to set up rocket production in military factory 333 near Heliopolis, south of Cairo, and at times up to 4,000 people were employed there. Sänger and three of his colleagues alone are said to have received a risk premium of 450,000 dollars per year, which was considerable by the standards of the time.76

Nasser had to raise enormous sums of money for his rocket program and in return received the first rockets as early as 1962, which he was able to proudly present at a parade in July of that year: the AL ZAFIR with a range of around 350 km and the AL-KAHIR with a range of around 600 km. The AL ZAFIR was more than 5 m long and carried a 500 kg conventional, high-explosive warhead. The AL-KAHIR was 12 m long and could carry a 750 kg warhead. Both had only one stage and were powered by kerosene and nitric acid. A year later, Nasser was able to demonstrate another type of missile, the two-stage AL-ARED, which was to carry two tons of explosives more than 1000 km and allegedly even 1 ton into a low orbit. An even larger rocket was planned, the three-stage AL-NEGMA, which was to use the two stages of the AL-ARED and the results of ELDO research for the third stage.

However, the technical problems were enormous, especially with guidance and flight control, so that in the initial phase of the flight the missile had to be controlled by wire. The missile project also came under political fire, especially from the Israeli government, which tried to end the program by diplomatic means and by using violence (kidnapping, bomb attacks) against the members of the missile team. The accusation by Israeli Foreign Minister Golda Meir that Egypt was developing weapons of mass destruction for its missiles prompted the German government under Ludwig Erhard to initiate the withdrawal of the missile experts in December 1963, at the cost of a diplomatic rupture with Egypt. Eugen Sänger and Armin Dadieu had already left under pressure from Bonn.

E.3 Space Planes and Space Shuttles

[In addition to the winged A-9 rocket, an even larger winged manned space vehicle capable of reaching New York was the Silbervogel (Silver Bird) prototype space shuttle designed by Dr. Eugen Sänger and Dr. Irene Bredt (who later married). A rocket-powered catapult sled on a 3 km long earthbound track would essentially serve as the first stage, and the rocket-powered Silbervogel would effectively be the second stage. The Silbervogel is relatively well known in the published literature [e.g., Griehl 2005 Vol. 2 and Myhra 2002], which tends to describe it as purely a paper design project that never found political and financial support for actual development and testing. For example, aerospace historian Manfred Griehl stated: "Since creation of such a dreadful project was pure fantasy in the 1940s, theoretical research work was halted and Professor Sänger himself was reassigned..." [Griehl 2005 Vol. 2 p. 329].

In contrast, several pieces of evidence suggest that major parts of the Silbervogel system were actually built and even tested; evidence also demonstrates the extensive influence of German-speaking scientists on the development of postwar space planes and space shuttles:

- Eugen Sänger and Irene Bredt completed and submitted a 900-page proposal giving details of the Silbervogel design and development program to the German government in 1941 [Myhra 2002].

- Wind tunnel models of Silbervogel are known to have been constructed and tested (p. 5595).

- At least one photograph exists of a full-sized Silbervogel engine that had been constructed for testing no later than 1944 (p. 5596).

- In January 1946, five Canadian aerospace experts reported that while visiting a German research station, they viewed "a rocket motor 10 times larger than those used on V-2s." That description could match either the Silbervogel motor or the A-10 booster rocket motor (p. 5470).

- Detailed orbital calculations were performed in 1944 to find the best trajectory for the Sänger-Bredt vehicle to reach New York (pp. 5597–5599).

- An article published in the 30 October 1944 *Daily Mail* reported that the Germans in occupied France had been constructing a "huge ramp" that was "intended as a launching place for flying bombs, which... would wreck New York." The size of the ramp, the reference to flying bombs, and the claimed target of New York seem consistent with the Silbervogel launch catapult (p. 5600).

- U.S. Army Air Forces Colonel Donald Putt, in charge of overseeing all German rocket scientists and related equipment and information rounded up at the end of the war, reported in March 1946: "Test model was made that carried one man and had landing gear, although it is not known if this model ever flew; it is known, however, that test runs were made on its engine."

Thus according to an authority with arguably the best access to the available information, the Silbervogel engine was constructed and tested, a Silbervogel vehicle complete with cockpit and landing gear was constructed, its engine was operational, and postwar U.S. officials were left wondering if flight tests of the Silbervogel may have even been conducted (p. 5601). What German witnesses and documents was this information based on? What became of the prototype Silbervogel vehicle—was it destroyed by the Germans, removed by the Americans, or removed by the Soviets?

- A lengthy and detailed October 1946 article in *Harper's Magazine* stated that the Silbervogel system "was never completed merely because of the war's quick ending" (p. 5490).

- A 1957 U.S. Air Force report stated: "The boost-glide concept was... partially tested by the Germans in the early 1940's" (p. 5603).

- Wernher von Braun and other German-speaking engineers published detailed descriptions and illustrations of a space plane in 1952 in *Collier's* magazine, in order to try to excite U.S. public interest and government funding for such a project [*Collier's* 1952-03-22].

- In 1946, Walter Dornberger began work on the Bell Aerospace GAM-63 RASCAL air-launched cruise missile, a large liquid propellant rocket with wings designed for long-range horizontal flight (p. 1854). In 1952, Dornberger led the Bell Aerospace team that proposed the Bomi (Bomber Missile) space plane, which was heavily based on the wartime Silbervogel designs—see p. 1932. In 1954, Dornberger's team designed the X-15 rocket plane, which had many similarities to the wartime manned A-9 designs [Käsmann 2013, p. 105]. After the Bomi proposal was rejected, Dornberger was instrumental in recycling the Bomi and Silbervogel designs to create the X-20 Dyna-Soar space plane; a prototype was built but the program was cancelled in 1963 [Robert Godwin 2003].

- Hans Multhopp (German, 1913–1972) designed the Martin Marietta X-24 lifting body, which first flew in 1969 [R. Dale Reed 1997, pp. 129–130, 136]; see pp. 1933 and 5612.

- In 1965, Walter Dornberger named the newest U.S. space plane program the "Space Shuttle" [Dornberger 1965a, 1965b].

- The U.S. Space Shuttle (Fig. 9.225) incorporated design features, experience, and personnel from the earlier A-9, Silbervogel, Bomi, Dyna-Soar, and X-24 space plane programs [Winter 1990, pp. 42–44, 113–122]; see pp. 5608 and 5610.

- Adolf Busemann (German, 1901–1986) suggested ceramic tiles for thermal insulation on the Space Shuttle, and also contributed his detailed knowledge of hypersonic aerodynamics and heating for the design and reentry [NYT 1986-11-05]; see p. 5611.

- Krafft Ehricke (German, 1917–1984) was deeply involved in space plane projects from Bomi to the Space Shuttle [Freeman 2008].

- The Space Shuttle Main Engines (SSMEs) were directly derived from engine designs with especially high combustion chamber pressures that were developed during and after the war (such as the MBB P111 engine and the Rocketdyne HG-3 engine) by Klaus von Riedel, Karl Stöckel, Hans Georg Paul, Dieter Huzel, and other German-speaking engineers (see pp. 5613–5617).

- The Space Shuttle Solid Rocket Boosters (SRBs) were based on enormous German-speaking contributions to solid propellant rockets (see Sections 9.8 and E.4).

Thus the Silbervogel and the manned winged A-9, as well as the German-speaking scientists who worked on them, led directly to postwar space plane programs such as the X-20 Dyna-Soar, the U.S. Space Shuttle (first launched in 1981, Fig. 9.225), the Soviet Buran (first launched in 1988, Fig. 9.227), and other space planes such as Dream Chaser (Fig. 9.228) [Chertok 2005–2012, Vol. 1, pp. 262–265; Winter 1990, pp. 42–44, 113–122].

Much more archival research on the wartime and postwar development of space planes by German-speaking scientists is necessary.]

Eugen Sänger and Irene Bredt. 1944. *Über einen Raketenantrieb für Fernbomber.* UM 3538. Ainring: Deutsche Luftfahrtforschung. English translation 1952. *A Rocket Drive for Long Range Bombers.* CGD-32, C-84296. Technical Information Branch, Buaer Navy Department. pp. 148, 152.

As an example of area attack with single propulsion and full turn, we use the attack on New York at a range of 6500 km. For c=4000 m/sec, the bomb load is 6 tons, and the detailed attack runs as follows: the motor starts to work 36 seconds after the take-off at 12 km. distance from the take-off point, and consumes the total fuel supply of 84 tons in the next 336 sec. At the end of the climb process, the aircraft reaches a velocity of 6370 m/sec, an altitude of 91 km, a distance of 736 km. from the point of take-off, and a weight of 16 tons. Using only its store of potential and kinetic energy, the bomber flies on to the point of bomb release, 5550 km. from the take-off point, and 950 km. in front of the target. At this point, which is reached 1150 sec. after take-off, the velocity has decreased to 6000 m/sec, and the stationary altitude to 50 km. After the bomb release the weight is 10 tons. Then the aircraft goes into a turn and in 330 sec. goes through a turn-spiral 1000 km. in diameter until it has reached the direction for the return flight to the home base. During turning, the altitude is greatly decreased in order to develop the aerodynamic forces necessary for the turn. At the end of the turn path, the velocity is still 3700 m/sec. and the corresponding stationary altitude is 38 km. The supersonic glide-path in the direction of the home base goes over 5450 km. in 2600 sec. and ends 100 km. before the home base at an altitude of 20 km. and velocity 300 m/sec. Subsonic glide and landing are completed in customary fashion. The whole flight lasts 4755 sec.

G. Ward Price, Fly-bombs Were Meant for U.S.: Huge Ramp Found. *Daily Mail.* 30 October 1944.

Immense concrete works on top of a hill in Artois, near Saint Omer, were intended as a launching place for flying bombs, which, the Germans boasted, would wreck New York.

Thousands of workmen were employed in tunnelling and building a cylindrical cupola on top of the hill, 250ft. in diameter.

Lorries, and even trains, could drive right into the heart of the hill.

German engineers told local French people that when the vast machinery was installed and ready to fire, the district would have to be evacuated for six miles around.

Frequent attacks by the R.A.F. kept on delaying work until the Allied advance from Normandy obliged all the enemy engaged on it to pack up hurriedly.

Footnote.—A German U-boat commander recently told naval cadets at Esjberg, Denmark, that Germany was preparing a new secret weapon for use against America. He said that U-boat crews would play a decisive part in the use of the weapon.

[This sounds like a launching sled track for Silbervogel, or possibly a slightly smaller launching track for the winged A-9 rocket.

The six-mile radius suggests that it would have been carrying a weapon of mass destruction. A 6-mile or 10-km blast radius would correspond to a ∼1.6 megaton bomb, which would suggest a hydrogen bomb and not a simple fission bomb.

Also see article on p. 5011 mentioning development of a catapult-launched atomic bomb delivery system in Norway. Could that have been a rocket-powered sled track for a Silbervogel or winged A-9?

Donald L. Putt. 1946. German Developments in the Field of Guided Missiles. *Society of Automotive Engineering (SAE) Journal (Transactions)* 54:8:404–411. [Putt 1946b]

One of the Germans' most fascinating projects was their long-range bomber. (See Fig. 14.) This was a liquid fuel supersonic pilot-controlled aircraft intended to fly from Germany to New York in 40 min at an altitude of approximately 154 miles. The motor was to weigh 2 1/2 tons and to deliver a thrust of 100 tons. This bomber was never finished, but it is believed that time was the only obstacle against its completion.

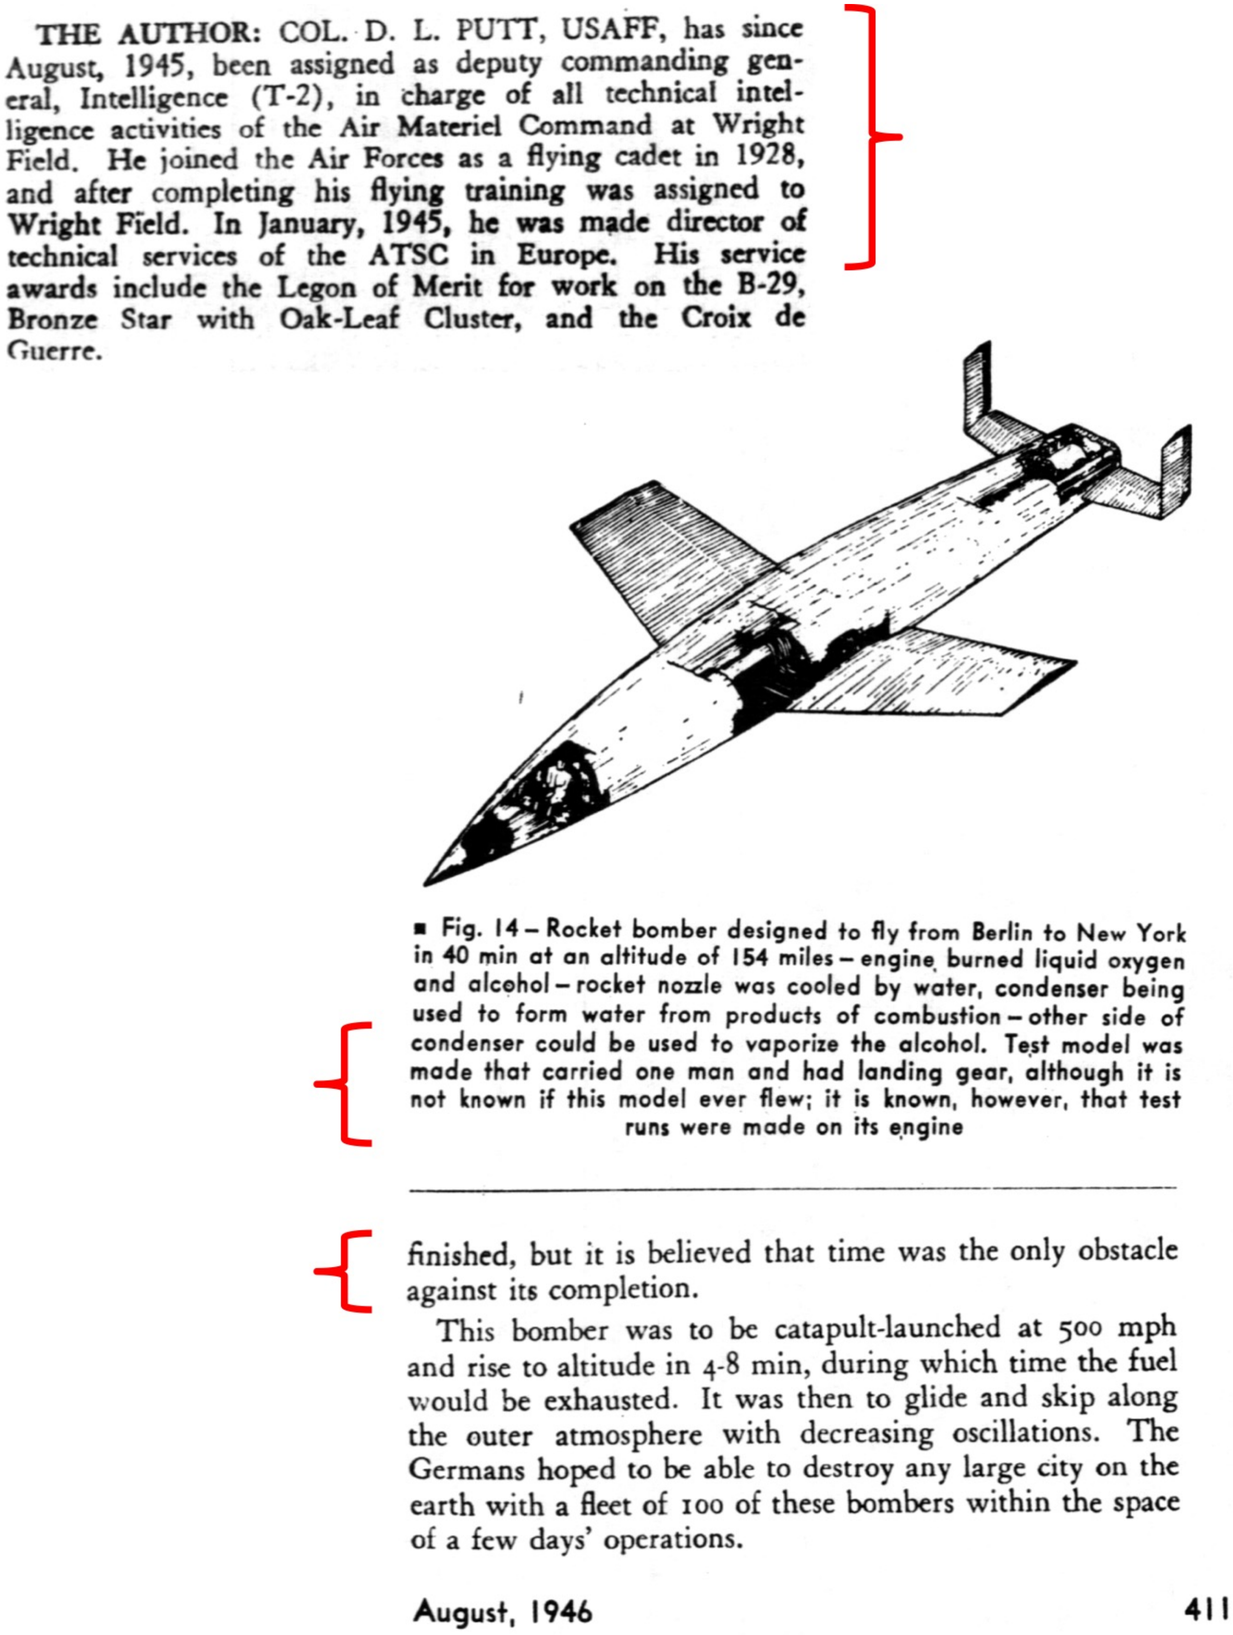
This bomber was to be catapult-launched at 500 mph and rise to altitude in 4–8 min, during which time the fuel would be exhausted. It was then to glide and skip along the outer atmosphere with decreasing oscillations. The Germans hoped to be able to destroy any large city on the earth with a fleet of 100 of these bombers within the space of a few days' operations.

Fig. 14—Rocket bomber designed to fly from Berlin to New York in 40 min at an altitude of 154 miles—engine burned liquid oxygen and alcohol—rocket nozzle was cooled by water, condenser being used to form water from products of combustion—other side of condenser could be used to vaporize the alcohol. Test model was made that carried one man and had landing gear, although it is not known if this model ever flew; it is known, however, that test runs were made on its engine

[Donald Putt was the U.S. Army Air Forces Colonel (later General) in charge of rounding up most of the German aerospace engineers in Europe at the end of the war, and funding them to continue their work in the United States for many years after the war. From that very well-informed position, he stated in this 7 March 1946 presentation to the Society of Automotive Engineers that the Silbervogel space plane was actually built, complete with cockpit, landing gear, and a functioning engine, and that it was possible that it was even test-flown.

Interestingly, his statement that the Silbervogel was actually built and might have been test flown (as well as some of his other statements about German rocket developments) vanished without explanation from later versions of this speech, such as the 27 June 1946 version written at Wright Field, possibly due to censorship:

Headquarters, Air Materiel Command, Wright Field, Dayton, Ohio. Library of Congress, Washington, DC. Call number MLCM 95/01648 (T) FT-MEADE.
- Donald L. Putt. 1946. World's Cities Threatened by Nazi Supersonic Bomber. *Society of Automotive Engineering (SAE) Journal* 54:7:9.]



THE AUTHOR: COL. D. L. PUTT, USAFF, has since August, 1945, been assigned as deputy commanding general, Intelligence (T-2), in charge of all technical intelligence activities of the Air Materiel Command at Wright Field. He joined the Air Forces as a flying cadet in 1928, and after completing his flying training was assigned to Wright Field. In January, 1945, he was made director of technical services of the ATSC in Europe. His service awards include the Legon of Merit for work on the B-29, Bronze Star with Oak-Leaf Cluster, and the Croix de Guerre.

Figure E.187: Donald Putt, who was in charge of collecting all technical intelligence from Europe for the U.S. Army Air Forces, published a written statement confirming that a manned Silbervogel complete with landing gear and a working engine was actually built during the war [Donald L. Putt. 1946. German Developments in the Field of Guided Missiles. *Society of Automotive Engineering (SAE) Journal (Transactions)* 54:8:404–411].

U.S. Air Force Air Research and Development Command. 1957. *Weapon Sys 464L Abbreviated Development Plan.* [Reproduced in Robert Godwin 2003, pp. 38–51]

[...] Briefly, this concept is characterized by a manned, winged vehicle, rocket-boosted to hypersonic speeds and altitudes above 100,000 feet, whereupon the vehicles operates in an unpowered gliding mode, trading kinetic and potential energy for ranges on the order of 5,000 nautical miles to 22,000 nautical miles depending upon the mission and time period.

The hypersonic boost-glide concept offers a major technological breakthrough in performance and mission capability which should be exploited in future reconnaissance and bombardment aircraft weapon systems. [...]

The boost-glide concept is not new. In the early Forties, Dr. Sänger, German rocket scientist, proposed a skip-glide vehicle to bomb New York from a launch site in Germany. Serious consideration was given this proposal by the Germans. A program known to the Germans as the A9/A10 development was designed to use a winged V-2 rocket as the second stage of a two-stage system. This vehicle was under development and test by the Germans when the war ended. At the close of the war Dr. Walter Dornberger, ex-German general and head of the Peenemunde Rocket Research Institute in Germany went to work for Bell Aircraft Corporation in this country. It is not surprising then that Bell approached the USAF in 1952 with an unsolicited proposal for a Manned, Hypersonic Boost-Glide Bomber/Reconnaissance Weapon System. Rand conducted investigations of this concept in 1948 and NACA published work on the subject in 1954. Since 1954, the ARDC has sponsored a considerable amount of work in the boost-glide field. The following table summarizes this effort. [Programs BOMI, Brass Bell, ROBO, HYWARDS, and now Dyna-Soar.]

[However far the development of Silbervogel actually got during the war, it led to many German-speaking engineers to develop additional space planes after the war.

After the war this approach was also championed by Walter Dornberger and other German-speaking scientists, ultimately leading to several vehicles: the U.S. X-20 Dyna-Soar that was built but not flown, the U.S. Space Shuttle, the Soviet Buran, and assorted other space planes that have been designed and in some cases flown.

Wernher von Braun and other German-speaking engineers published detailed descriptions and illustrations of a space plane in 1952 in *Collier's* magazine, in order to try to excite U.S. public interest and government funding for such a project [*Collier's* 1952-03-22].

In 1946, Walter Dornberger began work on the Bell Aerospace GAM-63 RASCAL air-launched cruise missile, a large liquid propellant rocket with wings designed for long-range horizontal flight (p. 1854). In 1952, Dornberger led the Bell Aerospace team that proposed the Bomi (Bomber Missile) space plane, which was heavily based on the wartime Silbervogel designs—see p. 1932. In 1954, Dornberger's team designed the X-15 rocket plane, which had many similarities to the wartime manned A-9 designs [Käsmann 2013, p. 105]. After the Bomi proposal was rejected, Dornberger was instrumental in recycling the Bomi and Silbervogel designs to create the X-20 Dyna-Soar space plane; a prototype was built but the program was cancelled in 1963 [Robert Godwin 2003].

Ultimately the work of these and other German-speaking engineers led to several space planes that were actually launched, including the U.S. Space Shuttle and the Soviet Buran.]

19. REPLACED PROJECT CARD AND PROJECT STATUS: This report supercedes DD Form 613 dated 31 Dec 56, System 459L (Brass Bell); DD Form 613 dated 28 Dec 56 System 610A (HYWARDS): and Task No. 89774 (ROBO) of DD Form 613 dated 8 Jan 57, Project 7990.

20. Requirement and/or Justification

This system is proposed to satisfy System Requirement 131, dated 14 November 1956, title: (U) Hypersonic Weapons Research and Development Supporting Systems; GOR No, 92 (TA-4e-1-59), dated 12 May 1955, title: (U) GOR For A Piloted Very High Altitude Reconnaissance Weapon System; and SR No. 126, dated 12 June 1956, title classified, Unclassified short titles ROBO.

The logical development of weapon systems utilizing the boost-glide concept encompasses the above requirements in the order mentioned. In keeping with the philosophy of "more Air Force per dollar" and the desirability of obtaining operational weapon systems of this type as early as practicable, it is essential that. weapon systems using the boost-glide concept be developed under a completely integrated program. This program consolidates the DD Form 613's previously submitted on projects. HYWARDS and Brass Bell (see Item 21e); the ARDC Form 111's dated 29 March 1957 and 10 May 1957 on Project 7990, Task 89774 (ROBO); and the Evaluation Report of the Ad Hoc Committee for ARDC System Requirement No. 126 ROBO dated 1 August 1957. This program is identified as Weapon System: 464L and given the nickname Dyna Soar, which stands for Dynamic Soarer. (Confidential)

21. Brief of Project and Objective

a. Brief and Military Characteristics

It is proposed that a development program for advanced weapon systems utilizing the boost-glide concept be initiated to take advantage of the tremendous capability and potential this concept offers in the accomplishment of Air Force missions of the 1967 through 1980 time period and beyond.Briefly, this concept is characterized by a manned, winged vehicle, rocket-boosted to hypersonic speeds and altitudes above 100,000 feet, whereupon the vehicle operates in an unpowered gliding mode, trading kinetic and potential energy for ranges on the order of 5,000 nautical miles to 22,000 nautical miles depending upon the mission and time period.

The hypersonic boost-glide concept offers a major technological breakthrough in performance and mission capability which should be exploited in. future reconnaissance and bombardment aircraft weapon systems.The tremendous improvements in speed, altitude, and range capabilities attainable simultaneously with such a system, warrant immediate initiation of a concerted development program to provide solutions to the technical problems involved in this concept.

Knowledge of the flight characteristics and equipment operation problems for the boost-glide flight regime is very limited.Ground based facilities such as wind tunnels, shock tubes, ballistic ranges and small scale flight models can provide an important portion of the required information.However, the inability of these ground facilities to simulate simultaneously the parameters encountered in actual flight requires design and development decisions to be made in many areas on the basis of unsubstantiated theory, inference, and extrapolation, unless actual flight data are available.The final critical evaluation of systems and components can only be accomplished with a full scale vehicle flying at the proper altitudes and speeds,

The development program, described herein, is designed to introduce boost-glide weapon systems into the USAF inventory in an appropriate time period compatible with weapon systems existing at that time and as a follow-on to the weapon systems becoming obsolete at that time. Considerable care has been taken in laying out the development schedule to avoid the necessity of a crash program in the development of boost-glide weapon systems.

(2) Administrative Approach

It is planned that management responsibility for this program will be assigned to the Directorate of Systems Management, Headquarters ARDC. A supporting team of technical personnel from WADC Laboratories and other appropriate ARDC Centers will be established to provide effective utilization of personnel and facilities available within ARDC. Support by the NACA in the form of over-all technical guidance and participation in the testing phases of this program is considered essential to the successful development of the proposed systems. Arrangements for NACA support and participation already initiated in this area will be expanded and finalized. A single contractor will be selected to accomplish the exploratory research part of the Pre-Phase I investigation program giving due consideration to all capable contractors in the field. This work must be non-proprietary in nature and must be accomplished under paid Air Force contract. The second part of the Pre-Phase I program, that of design studies and systems analysis, will be carried out on a competitive basis under paid and/or voluntary studies and the data generated will be proprietary. Two or more contractors will be selected for competition under this part of the Pre-Phase I program. It will be made clear at the outset that all of the contractors involved in the Pre-Phase I program will have an equal opportunity to compete for the Phase I of the conceptual test vehicle. This philosophy is applied throughout the development schedule for all Dyna Soar vehicles. Proprietary rights of contractors competing in the design study and system analysis phase will be protected as necessary to maintain their competitive position. Technical data from WS 107A has been and will be utilized to the maximum during this program. In addition, studies of the designs and concepts of the Dyna Soar program will show cognizance of the facilities, support equipments, concepts, etc. being developed for the WS 107A.

A more thorough treatment of the Dyna Soar program, including justification for the weapon systems proposed and the test vehicle required, the development philosophy, and a thorough discussion of the development schedule is contained in Attachment 3.

c. Background History

The boost-glide concept is not new. In the early Forties, Dr. Sanger, German rocket scientist, proposed a skip-glide vehicle to bomb New York from a launch site in Germany. Serious consideration was given this proposal by the Germans. A program known to the Germans as the A9/A10 development was designed to use a winged V-2 rocket as the second stage of a two-stage system. This vehicle was under development and test by the Germans when the war ended. At the close of the war Dr. Walter Dornberger, ex-German general and head of the Peenemunde Rocket Research Institute in Germany went to work for Bell Aircraft

Figure E.191: U.S. Air Force Air Research and Development Command. 1957. *Weapon Sys 464L Abbreviated Development Plan.* [Robert Godwin 2003, pp. 38–51].

Boris Chertok. 2005–2012. *Rockets and People.* 4 vols. Washington, DC: U.S. Government Printing Office.
[**https://www.nasa.gov/connect/ebooks/rockets_people_vol1_detail.html**]

[Vol. 1, pp. 262–265:] The collective panel of experts that was set up there on the spot determined that this document was the design for a rocket-powered bomber. [...]

As far as I was able to understand later, this was not the design of theA-9/A-10 missile, which was designed for a range of 800 kilometers. The report discussed the ranges required to strike New York. From today's standpoint, we can say that the layout of the vehicle described in the report—found in the woodpile in Peenemünde in May 1945—anticipated the structure of the American Space Shuttle and our Energiya-Buran system. [...]

The report had been issued in Germany in 1944. Its authors were the Austrian rocket engine researcher E. Sänger, who was already well known before the war, and I. Bredt, who was unknown to us and was later identified as Irene Bredt, a gas aerodynamics specialist.

Eugen Sänger was known for his book *Raketen-flugtechnik* (The Technology of Rockets and Aviation), which he published in 1933. It had been translated and published in the Soviet Union. Back when he was a 25-year-old engineer, Sänger was captivated by the problems of rocket technology. He was one of the first serious researchers of gas dynamic and thermodynamic processes in rocket engines.

You can imagine how Bolkhovitinov and other NII-1 specialists felt as they leafed through the top-secret report, one of 100 printed copies. Judging by the distribution list, it had been sent to the leaders of the *Wehrmacht* main command, the ministry of aviation, to all institutes and organizations working in military aviation, and to all German specialists and leaders who were involved in rocket technology, including General Dornberger in the army department of armaments, who also served as chief of the Peenemünde center.

The title of the report was "Über einen Raketenantrieb für Fernbomber" (On a Rocket Engine for a Long-Range Bomber). This paper analyzed in great detail the technical capabilities for creating a manned winged rocket weighing many tons. The authors convincingly showed by constructing nomograms and graphics that with the proposed liquid-propellant rocket engine with a thrust of 100 metric tons it was possible to fly at altitudes of 50–300 kilometers at speeds of 20,000–30,000 kilometers/hour, with a flight range of 20,000–40,000 kilometers. The physical and chemical processes of high-pressure and high-temperature propellant combustion were studied in great detail, along with the energetic properties of propellants, including emulsions of light metals in hydrocarbons. The work proposed a closed, direct-flow, steam power plant both as a cooling system for the combustion chamber and as a means to activate the turbopump assembly.

The problems of aerodynamics for an aircraft with a speed ten to twenty times greater than the speed of sound were new for our aerodynamics specialists.The report went on to describe the launch, takeoff, and landing dynamics. In an apparent attempt to interest the military, the report included a highly detailed examination of bombing issues, considering the enormous speed of a bomb dropped from such an aircraft before it approached the target.

It is interesting that Sänger had already shown by the early 1940s that launching space aircraft without auxiliary means was unacceptable. He proposed launching space aircraft using a catapult with a horizontal track that would enable the aircraft to reach a speed greater than the speed of sound. [...]

The total takeoff weight of the bomber was 100 metric tons, of which 10 metric tons was the weight of the bombs.The landing weight was assumed to be 10 metric tons. If the flight range were reduced, the weight of the bombs could be increased to 30 metric tons.They proposed that the subsequent work to implement the design of the rocket-propelled bomber be divided into twelve stages, in which the bulk of the time would be devoted to firing rig optimization of the engine, rig testing of the interaction of the engine and aircraft, launcher testing, and finally, all phases of flight tests.

In 1945, the work of Sänger and Bredt was translated, and in 1946 it was published under the title "Survey of Captured Technology" by the Military Publishing House of the USSR Armed Forces Ministry, under the editorship of Major General of the Aviation Engineer Service V. F. Bolkhovitinov; a large number of copies were printed.

Being in Germany at the time, Isayev and I had no idea that this report had caused quite a stir after its delivery to NII-1 in May 1945.We could only imagine the feelings experienced by our patron, who was considered a dreamer in higher aviation circles, but who was respected for his enthusiasm in the face of extremely bold proposals, a quality that was very unusual for a chief designer.Together with the engine specialists from RNII, we had only obtained a reliable liquid-propellant rocket engine with a thrust of 1.5 metric tons in 1943. Isayev dreamed of bringing the engine up to a thrust of 2–3 metric tons in a year or two. But then, in 1944, a V-2 engine with a thrust of almost 30 metric tons was recovered in Poland. Added to this now was Sänger's report, which outlined the design for an aircraft with engine thrust of 100 metric tons!

When Bolkhovitinov's deputy, MAI professor Genrikh Naumovich Abramovich, flew into Berlin from Moscow in June, he was already familiar with Sänger's work. Being a very erudite theoretician, he said that such an abundance of gas-kinetic, aerodynamic, and gas-plasma problems required a profound scientific analysis. He believed it would take ten years—God willing—before it came down to the business of designers."It's easier to make rockets than that airplane."

Yes, that proposal was at least twenty-five years ahead of its time. The first space aircraft in the form of the Space Shuttle flew in 1981. But it launched vertically as the second stage of a rocket. To this day there is no authentic aerospace vehicle with a horizontal launch.

Frank Winter, U.S. National Air and Space Museum Curator [Winter 1990, pp. 42–44, 113–119, 122]

The Space Shuttle concept also originated in the 1920s and 1930s. [...]

Eugen Sänger of Austria, who held a doctorate in aeronautical engineering from Vienna's Technische Hochschule, focused on the rocket-propelled stratospheric plane. [...]

From the start [1920s], Sänger favored the reusable rocket plane over "ballistic" systems[...]

After the war, as leader of the newly formed International Astronautical Federation, Sänger became a tireless advocate of the spaceplane. He died in 1964, before he could see his Silver Bird take flight, greatly modified in the form of the Space Shuttle. [...]

Two early postwar designs based on his work, as well as on the winged V-2s, were by von Braun and Dornberger. Von Braun's idea, the more famous, was introduced in the March 22, 1952, issue of *Collier's* magazine as part of a marvelously illustrated series on manned spaceflight. [...]

At about the same time von Braun was drafting these concepts (1951–1955), Walter Dornberger and Krafft Ehricke were working at Bell Aircraft on the highly classified Bomi (Bomber-Missile) study for the Air Force. [...T]he Bomi owed much to the Antipodal Bomber. [...]

Meanwhile, the Air Force was developing three projects similar to the Bomi. [...] In October 1957 the three were consolidated into the Air Force's X-20, known as the Dyna-Soar (Dynamic Soaring) vehicle, so called because it combined ballistic missile lift with the soaring and precise flight control of an airplane. For the same reasons, it was also called a boost-glider. In its brief, controversial carrier, the Dyna-Soar nearly became the very first Space Shuttle. [...]

The PRIME project (Precision Recovery Including Maneuvering Entry) was the second phase of START. Three PRIME vehicles, flown between 1966 and 1967 and boosted into space by Atlas launchers, were likewise small unmanned gliders but were true lifting bodies. [...]

The X-24B made especially valuable contributions toward the Shuttle, not only by gathering data on aerodynamics and handling but also by test-flying components later incorporated in the Shuttle's orbiter (the manned spaceplane which orbits the Earth). In addition, the X-24B showed that a spaceplane did not need any cumbersome auxiliary turbojet or other powerplant to land, as some designs of the time required. [...]

The years 1969 to 1972 thus represented an intense period of evolution, during which the Shuttle design was refined on the basis of many proposals. [...]

One remarkable feature of the Shuttle is its reusable thermal protection system. This consists of four types of insulation, which are used on various parts of the ship according to the heat protection required. The most critical areas are the underside and the leading edges of the wings and body, which reach a searing 1,200–2,300 degrees Fahrenheit during reentry. Here are glued 30,922 individually contoured tiles made of silicon carbide and carbon cloth.

[High-temperature ceramics for the Space Shuttle trace back to wartime German work on high-temperature ceramic components for turbojet engines.

Suitable shapes for hypersonic reentry and the suggestion to use ceramic tiles both came from Adolf Busemann at Langley–see the obituary for Adolf Busemann below.

In 1965, Walter Dornberger named the newest U.S. space plane program the "Space Shuttle" [Dornberger 1965a, 1965b].

Krafft Ehricke (German, 1917–1984) was deeply involved in space plane projects from Bomi to the Space Shuttle [Freeman 2008].

The X-24 lifting body design came from Hans Multhopp [R. Dale Reed 1997, pp. 129–130, 136]; see pp. 1933 and 5612.

The Space Shuttle Main Engines (SSMEs) were directly derived from engine designs with especially high combustion chamber pressures that were developed during and after the war (such as the MBB P111 engine and the Rocketdyne HG-3 engine) by Klaus von Riedel, Karl Stöckel, Hans Georg Paul, Dieter Huzel, and other German-speaking engineers (see pp. 5613–5617).

The Space Shuttle Solid Rocket Boosters (SRBs) were based on enormous German-speaking contributions to solid propellant rockets (see Sections 9.8 and E.4).]

Adolf Busemann, 85, Dead; Designer of the Swept Wing [NYT 1986-11-05]

Adolf Busemann, whose design of the swept wing for aircraft helped make supersonic flight possible, died Monday at the Fraiser Meadows Manor Health Care Center here. He was 85 years old.

Mr. Busemann, a native of Luebeck, Germany, presented his discovery at the Volta Congress in Rome in 1935. After World War II, he carried on his research in the United States.

The swept-wing design was used in American F-86 and Soviet MIG-15 jet fighters in the Korean War.

He had held a professorship in aerospace engineering at the University of Colorado since 1963. Research in wind tunnels led him to advise the National Aeronautics and Space Administration on the use of ceramic tiles, which could withstand high temperatures better than aluminum, on the space shuttle.

R. Dale Reed, retired NASA engineer who worked on the lifting body reentry tests that paved the way for the U.S. Space Shuttle [R. Dale Reed 1997, pp. 129–130, 136].

A high-volume lifting body, the SV-5 was the brain child of Hans Multhopp, an aerodynamicist at the Martin Aircraft Company. The SV-5 quickly became the centerpiece of a new Air Force program known as START (Spacecraft Technology and Advanced Reentry Tests). Established in January 1964, START consisted of dual programs—the unpiloted PRIME (Precision Recovery Including Maneuvering Entry) and the piloted PILOT (Piloted Lowspeed Tests).

In early 1964, I visited the Martin Aircraft Company to gather information on the SV-5 and possibly gain some support from Martin and the Air Force in convincing NASA management to fund a supersonic lifting-body flight-test program. I met Hans Multhopp, introduced to me as Martin's chief scientist and the designer of the SV-5. A soft-spoken man with a heavy German accent, Multhopp seemed to be highly respected and admired by others in Martin engineering. After a conversation with him about the SV-5, I could understand why he was so highly respected, for his knowledge of aerodynamics and aircraft design was impressive.

A former aeronautical engineer, Multhopp had worked during World War II for the Focke-Wulf Flugzeugbau in Bremen, Germany, first as head of the aerodynamics department and then as chief of the advanced design bureau. One of his projects at Focke-Wulf was designing, in conjunction with Kurt Tank, the Ta-183. Information on the Ta-183 design obtained by the Russians at the end of World War II greatly influenced the design of the Russian MIG-15 jet fighter. The Pulqui-II, a derivation of the Ta-183 design flown in Argentina after World War II, had been built by former Focke-Wulf employees who had fled to Argentina.

Whisked out of Germany at the end of World War II, Multhopp went to work for the British at Farnborough. There, he designed the swept-wing British Lightning fighter, using calculation techniques he had developed. After four years, however, the British found his arrogance intolerable and he was sacked. He then became the chief scientist for the company that eventually became the giant American aviation and space contractor, Martin Marietta.

Multhopp was able to convince Martin management as well as the Air Force that the SV-5 shape was superior to NASA's M2-F3 and HL-10 shapes on the basis of six features. First, the SV-5 was a maneuverable lifting body with no essential surface components that would be destroyed on reentry from orbit. Second, the vehicle had a hypersonic lift-to-drag ratio of 1.2 or better, permitting a lateral range of 1,000 miles. This feature would enable a recall to any preselected site at least once a day as well as emergency recall to a suitable location from every orbit.

Third, the low-speed aerodynamics of the SV-5 were suitable for making a tangential landing without resort to automatic controls. Fourth, volumetric efficiency was as high as possible, the shape giving as much volume forward as possible for center-of-gravity control. The resulting configuration gave more room up front for the pilot and equipment. The center-of-gravity could then be positioned sufficiently forward to provide adequate vehicle control without resorting to an unstable vehicle with a negative static margin. Fifth, positive camber was included in the body, allowing trimmed lift conditions at lower angles of attack as well as a high subsonic lift-to-drag ratio of about 4.0. Sixth, in regards to pilot visibility, the SV-5 cockpit canopy design was superior to that of the M2-F3 and the HL-10.

My first meeting with Hans Multhopp at Martin in early 1964 also turned out to be my last. After that visit, he seemed simply to disappear from public view. Later, when the X-24A was being flown at Edwards Air Force Base as the final stage of the PILOT portion of the SV-5 program, I was surprised to learn that my Air Force colleagues at Edwards had never even heard of Hans Multhopp. At that time, there was still considerable resentment in this country about using German engineers in American aerospace projects. Consequently, it became the usual practice to keep German engineers at low profile. However, this was not always true. A good example of an exception to this practice was Wernher von Braun, who rose to high rank in NASA in full public view and made a significant contribution to our space program. [...]

By combining much larger fuel tanks with a lighter-weight structure in the X-24A, Hans Multhopp and the other Martin designers theoretically achieved the potential for the X-24A to attain much higher speed and altitude than either the M2-F3 or the HL-10.

Dan Sharp. 2016. *Luftwaffe Secret Bombers of the Third Reich.* Horncastle, U.K.: Mortons. pp. 127–129.

KARL STÖCKEL ROCKETS AND RAMMERS

Another DVL employee who dreamed up unusual concepts with advanced features was Karl Stöckel. During 1944, when the effects of Allied bombing were becoming increasingly significant for Germany, he began thinking of specialised aircraft that might be able to tackle the incoming enemy bombers. It was noted in Luftwaffe: Secret Jets of the Third Reich that what was frequently referred to as the Blohm & Voss MGRP 'Manually Guided Rocket Projectile' might well be one of a series of 'rammer', ramjet and rocket concepts drafted by Stöckel—and this can now be conclusively verified.

A drawing showing a 'Manuell gesteuertes Raketenprojektil' has been discovered, signed by Stöckel and dated August 23, 1944. It shows a large missile, similar in size to a V2, with a very small parasite aircraft attached at its base—barely large enough for one man. The missile would weight five tonnes, the aircraft 0.5 tonnes and the remaining 4.5 tonnes of the combination's all-up weight would be rocket fuel. A diagram and notes on the same sheet indicate how the MGRP was intended to operate. [...]

After the war, Stöckel seems to have gone on to work for Bölkow, designing and patenting a series of rocket engine chambers during the 1950s and 1960s.

[Karl Stöckel began his career by designing rocket planes that would be carried aloft by riding piggyback on the side of a larger rocket booster, essentially a miniature version of what the U.S. Space Shuttle was when it finally launched nearly four decades later.

To power such vehicles, Stöckel spent most of the rest of his career designing and building ever more sophisticated rocket engines capable of operating with especially high combustion chamber pressures (in order to maximize the thrust-to-weight ratio of the engines). The best known of Stöckel's own engines was the Bölkow/MBB P111, which caught the eye of other German engineers at Rocketdyne and NASA and directly led first to the Rocketdyne HG-3 engine and ultimately to the Space Shuttle Main Engines (SSMEs).]

Karl Stoeckel. 1985. History of Development of Staged Combustion Rocket Engine in Germany. [https://www.researchgate.net/publication/293622179_History_of_Development_of_Staged_Combustion_Rocket_Engine_in_Germany]

The development history of the staged combustion engine begins with preliminary studies for interceptors at DVL Berlin during the war, continues with the first test runs using small LOX-regeneratively cooled copper combustion chambers at Boelkow KG in Stuttgart in 1957 and culminates in the 50 kN-LOX/Kerosine staged combustion engine P 111 at MBB in Ottobrunn in 1965. This particular high pressure engine was the first of its kind in the history of rocketry and influenced the development of the space shuttle main engine (SSME) with the H 13 combustion chamber. Subsequent development work continued until 1975 at MBB with the planned 200 kN-LH_2/LO_2 high pressure stage engine H 20 for ELDO III, the combustion tests up to a pressure of 200 bar with the N_2O_4/UDMH-copper chamber M 1 in Ottobrunn and finally the development and manufacture of the LH_2/LO_2 combustion chamber HM 7 for the third stage of Ariane. Past work shows that continued development of high-pressure engine for future applications still has potential.

Christophe Rothmund, Helmut Hopmann, and Erich Kirner. 1992. The early days of LOX/LH2 engines at SEP and MBB. IAF, 43rd International Astronautical Congress, Washington, D.C. Aug. 28–Sept. 5, 1992. [https://www.researchgate.net/publication/234528704_The_early_days_of_LOXLH2_engines_at_SEP_and_MBB]

The development of cryogenic LOX and LH2 rocket engines is reviewed for two European manufacturers. Of note are: (1) the HM4 early turbopump LOX/LH2 engine; (2) the P111 engine with a staged combustion cycle and oxygen-rich preburner; (3) a thrust-chamber program; and (4) the development of LOX-cooled bearings, dynamic LOX seals, and LOX inducers. Launchers were developed by these manufacturers that incorporated LOX and H2O technologies, and the Europa is emphasized. These developments led to collaboration on the Ariane series of Vulcain rocket motors which relied heavily on the technologies established for the HM7 engine. The correction of ignition delays and bearing instabilities in these engines led to a class of rocket engines with a wide range of applications.

Frank-E. Rietz. 2006. EADS Expertise on the Space Shuttle: An Idea Catches On. *Planet AeroSpace* 2006:2:76–78.

Which is where EADS technology comes into play, for the space shuttle main engines work on a principle that originated south of Munich. The design of these innovative engines was conceived 50 years ago—in 1956—at Bölkow GmbH, a predecessor of EADS.

The historical roots of this engine design actually go back even further, to an original idea dating from 1942. Karl Stöckel, an aeronautical engineering graduate who later worked for Bölkow, devoted his research to ultra-high velocity aircraft and possible means of propelling them. He was particularly interested in the concept of combined rocket and turbojet propulsion. Stöckel believed it was crucial to raise the pressure in the combustion chamber to a point where it would meet flightworthiness requirements in terms of compact architecture, low weight and low fuel consumption. The pressure in standard combustion chambers could not be raised above the level of 15 bars, which is why conventional rocket engines work on what is known as the bypass flow principle. This means that the gas generator with the turbine driving the fuel pumps is installed parallel to the thrust chamber. Inevitably, this technique results in loss of momentum and a significant drop in efficiency. The new concept involved 'staged combustion', with combustion taking place in two successive stages. In the first stage of this arrangement, a certain amount of the fuel is burnt up at high pressure in a pre-burner to generate the gas that drives the turbines for the fuel pumps. In the second stage, the gas is mixed with fuel and burns up completely in the combustion chamber. At the same time, a means of cooling the combustion chamber was discovered: the liquid oxygen flowing round the combustion chamber through an arrangement of channels, cooling the chamber and being itself heated in readiness for the combustion process.

Practical testing of this type of engine began on 1 September 1956. The following year, the German ministry of defence awarded Bölkow a contract to develop the full-flow engine. Development of the P111 test engine began in 1958 as soon as the company had relocated from Stuttgart to Ottobrunn. In the months and years that followed, the Bölkow engineers learned important lessons on the structure and function of high-pressure engines. They conducted research into ignition and combustion processes, cooling requirements and heat transfer ratios and paved the way for copper combustion chambers with axial cooling channels. This made it possible to increase chamber pressure to 100 bars. In 1963, only five years after the start of development, the full-flow engine underwent its first test run. And finally, the innovative rocket engine was presented to experts at the 1966 Hanover air show.

NASA began to take an interest in the full-flow engine during its preliminary studies for the space shuttle. Working in conjunction with the U.S. company Rocketdyne, specialists at Ottobrunn developed an engine based on the full-flow principle. During their test runs they achieved a chamber pressure of 282 bars—a world record even today. NASA decided to adopt full-flow engine technology for the shuttle, and this in turn brought licence fees for the German company. Ever since the first flight of Columbia 25 years ago, the technology from Ottobrunn has proved its worth in the entire shuttle fleet.

Roland Kindermann, Steffen Beyer, Peter Bichler, Wolfgang Keinath, Torsten Sebald. Advanced Production Technologies for Thrust Chambers of Liquid Rocket Engines. AAAF Paper 16_96_P, 6th International Symposium for Space Propulsion.

The forebear of today's rocket combustion chamber was tested in Berlin under the leadership of Klaus von Riedel. This was the first time that new, good heat-conducting materials such as aluminum and copper, were used for a thin-walled combustion-chamber liner instead of the steel that was commonly used at the time. Technologies for forced cooling under high pressure were also being used, as was fuel injection through jets. The years to follow saw ever-increasing requirements for higher pressures combined with efforts to arrive at a compact construction, low weight and minimized fuel consumption. There was therefore a move towards main flow engines with the aim of achieving the desired cooling for an increase in power. Development of the P111 (Figure 1) commenced at Astrium, the space subsidiary of EADS (European Aeronautic Defense and Space Company) and ushered in a 40-year tradition of liquid engines.

Processes such as cool-channel milling, waxing the channels and electronickeling were used in the manufacture of the support liner. A successful test was carried out in 1963 using a LOX/kerosene fuel mixture, achieving a thrust of 49 kN at a pressure of 85 bar. The first engine powered by LH2/LOX, the RL10, was successfully produced in the USA over the same period. At the close of the 1960s, the experience thus obtained led to a transatlantic joint venture between Astrium and Rocketdyne. A heat test performed during the course of this cooperation produced a world record that is still in place today: chamber pressure of 282 bar. The construction and operation of the P111 was patented by MBB. It later formed the basis for developing the high-energy SSME by NASA. The 1970s saw the commencement of the long period of technological cooperation between France and Germany. The two countries were working on the joint development of their own cryogenic engines. The HM7 engine for the Ariane 4 was the first LOX/LH2 to be developed outside the USA. The fast expanding market for satellites placed increasingly large demands on launcher payloads and it was essential to develop Ariane 5. Requirements of 100 bar or more for chamber pressures and exceptional heat flux entailed a new combustion chamber material with the relevant physical and mechanical properties.

Successful development of the Narloy-Z copper-based alloy for the combustion chamber of the Space Shuttle Main Engine (SSME) constituted the foundation stone for the development and introduction of the European variant CuAgZr as the combustion chamber material used in the Vulcain engine powering Ariane 5. The principle of construction based on HM7 production technology was transferred to the low-energy upper stage rocket of Ariane 5, the Aestus engine. The corrosion fuel combination used with Aestus (MMH/N2O4) and the low thermal load involved selecting an austenitic chromium-nickel steel (1.4546) for the combustion chamber.

Mike Wright. 1995. MSFC Propulsion Center of Excellence is Built on Solid Foundation [https://web.archive.org/web/20150427090253/http://history.msfc.nasa.gov/saturn_apollo/propulsion_center.html].

Space Shuttle Main Engine

The last Saturn F-1's that NASA employed helped lift Skylab into orbit in 1973. By then, NASA engineers were already deep into the design for the space shuttle main engine, a concept that broke with the past, according to shuttle historian Dennis R. Jenkins. The challenge, Jenkins said, was "not to build a larger, more powerful engine, but to build a small, compact engine that could be throttled during ascent to provide some measure of control over the maximum dynamic pressure and speed of the vehicle." MSFC engineers who have traced the technology projects leading to the development of the space shuttle main engine have pointed to an "aggressive technology program in high-pressure tubomachinery initiated in the 1960's." They point out that much of the work was done by Pratt & Whitney under MSFC's sponsorship, with outgrowth known in-house as the concept for the HG-3, a 350,000-pound-thrust engine named after Hans G. Paul, the long-time chief of the Propulsion Division. In essence, the HG-3 concept eventually became the space shuttle main engine. [...]

E.4 Submarine-Launched and Solid Propellant Rockets

[This section concerns submarine-launched missiles that were developed or were under development during the war, including submarine-launched versions of small rockets, V-1, V-2, and other missiles, as well as the postwar influence of such projects and German-speaking scientific experts. This section also presents numerous sources about the wartime and postwar development of solid propellant rockets. Not all submarine-launched missiles used solid propellant, and not all solid propellant rockets were designed to be launched from submarines, but the two histories are so deeply intertwined (because solid propellant is especially desirable for submarine-launched rockets) that they are presented here in the same section.

Official histories claim that the major innovations underlying modern solid propellant rockets and submarine-launched ballistic missiles (SLBMs) were invented primarily in the United States, and primarily after World War II. For example, Vaclav Smil, a prolific science historian at the University of Manitoba, wrote [Smil 2006, p. 84]:

> In 1942 John W. Parsons, an explosives expert at California Institute of Technology, formulated the first castable composite solid propellant by combining asphalt (fuel and binder) with potassium perchlorate (an oxidizer).
>
> Key improvements in the preparation of these propellants were made during the late 1940s and the early 1950s. In 1945 Caltech's Charles Bartley and his coworkers replaced asphalt with Thiokol (synthetic rubber). This polysulfide polymer was synthesized for the first time in 1926 by Joseph C. Patrick, and the eponymous corporation was formed in 1928. In 1947 Thiokol Corporation began the systematic, and still continuing (now as Morton-Thiokol), development of solid propellant rockets. The second key innovation was the replacement of potassium perchlorate by ammonium perchlorate (AP) as an oxidizer. Another critical discovery was made at the Atlantic Research Corporation by Keith Rumbel and Charles B. Henderson, who found that adding large amounts of aluminum (Al) greatly increased the specific impulse of composite propellants: they used 21% Al, 59% AP, and 20% plasticized polyvinyl chloride (PVC).
>
> Solid propellants, configured inside the casings mostly in five- to twelve-pointed stars, were used in America's first SLBMs (*Polaris* in 1960, with AP/Al/polyurethane propellant) and ICBMs.

However, evidence demonstrates that these innovations were imported from earlier German-speaking scientists and engineers:

- During the war, German-speaking scientists developed and demonstrated solid propellant rockets that used ammonium perchlorate oxidizer (pp. 5684, 5690).

- The same German-speaking scientists also developed and demonstrated solid propellant rockets that used polybutadiene "buna" synthetic rubber in the propellant to act as both fuel and binder (pp. 5684, 5690).

- The same German-speaking scientists also added plasticizers to enable the propellant to be molded into any desired shape, to adhere tightly to metal walls, and not to be prone to crumbling or brittleness (pp. 5684, 5690).

- During the war, German-speaking scientists added powdered aluminum to rocket propellants and closely related solid explosives in order to improve performance (pp. 5692–5695).

- During the war, German-speaking scientists used a wide variety of grain designs for the geometrical shape of the combustion surface inside the propellant to give the desired variation of thrust with time (pp. 5668–5669, 5690, 5695).

- The Rochen ammonium perchlorate/polybutadiene short-range missile was first fired in 1944 (p. 1911).

- The Rheintochter two-stage solid-propellant surface-to-air missile was first launched in 1943 (p. 1912).

- The Rheinbote four-stage solid-propellant long-range rocket was first launched in 1943 (p. 1913).

- The V-101, an ammonium perchlorate/polybutadiene propelled, 140-ton, 30-meter-tall, long-range ballistic missile, was under development when the war ended 1914).

- Submarine-launched small ballistic rockets were successfully demonstrated during the war (pp. 5628–5645).

- Submarine-launched V-1 cruise missiles were developed, tested, and possibly even deployed (pp. 5618–5627).

- Methods of firing large ballistic missiles from deeply submerged submarines were perfected by the end of the war (p. 5747).

- Towed submarine carriers for A-4 or V-2 rockets were designed and possibly developed during the war (pp. 5628–5660).

- Rockets with dimensions suitable for submarine launch were developed by wartime laboratories under contract with the German navy (p. 5532).

- An August 1945 U.S. report stated that the Germans had developed a wide variety of guided missiles including “underwater launched to air,” “surface,” and “underwater targets” (p. 5429).

- German-speaking scientists were directly involved in developing Jupiter, a postwar U.S. ballistic missile designed to be launched from submarines (but ultimately only deployed on land; see p. 5501).

- German-speaking scientists were deeply involved in the development of the U.S. Polaris, Pershing, and Minuteman solid propellant ballistic missiles in ways that have never been fully disclosed to the public (pp. 5700–5736).

The wartime and postwar German technologies and the associated scientists were directly responsible for the development of large solid propellant rockets for modern ballistic missiles, strap-on rocket boosters, and some satellite launch vehicles.

The German-derived technologies and scientists led directly to the postwar development of submarine-launched nuclear missiles, the third component of the nuclear triad. (Thus the entire modern nuclear triad was a wartime German creation.) The wartime programs included both submarine-launched ballistic missiles—direct ancestors of postwar SLBMs such as Polaris, Poseidon, and Trident—and submarine-launched V-1 cruise missiles—direct ancestors of modern versions such as the U.S. Tomahawk and Russian Kalibr.]

Neal Stanford. Must Be Last War. *Wilmington Star* (North Carolina), 31 October 1944, p. 4. [**https://chroniclingamerica.loc.gov/lccn/sn78002169/1944-10-31/ed-1/seq-4**]

Five times, one day, this week, Washington correspondents lived through buzz-bomb raids. Vicariously, to be sure, and the raids were only nine minutes each.

But that was more than enough for most. It was more than enough to persuade all that in these robot bombs, these rocket bombs, rumors of atomic bombs, the world had something which, if not controlled, would destroy it. Truly the world has a bear by the tail and can't let go. Its only choice is to tame it.

Buzz-bombs have such tremendous destructive potentialities that despite Britain's suffering from this menace that has killed over 5,000, injured 16,000 more, destroyed 23,000 homes, churches, hospitals, stores, schools in London, and damaged 1,000,000 more, we have only begun to feel its power of devastation.

That lesson was shouted from every foot of the film—with appropriate sound effects—that the British Information Service showed, for the first time either in Britain or the United States, to the Washington press corps. We saw these bombs hurtling through Britain's skies, morning, noon, and night. We heard them zooming overhead as rescue crews dug out hapless victims of V-1. We watched them in fascination plummet to earth and explode in a blast of smoke. And we gloried in Britain's defenses, ack-ack gun crews, Spitfires, barrage balloons that caught over half of the 8,000 mechanical buzzards in flight. But thousands out-sped defenses. We realized only too well why buzz-bombs were not a peculiarly British problem—why they were our problem as well.

This nine-minute capsule of buzz-bomb terror, it is expected, will shortly be shown widespread over the United States. Its purpose is to educate, to awaken, to arouse—not to entertain or cause fear. For while 50,000,000 Britons know that the buzz-bomb, the rocket bomb, the automatic bomb have made this war civilization's last hope, there is no similar assurance that 135,000 Americans are irrevocably committed to working to make this the last war. It may be their aim, but is it their determination?

The V-1, or buzz-bomb, is still hitting England from time to time. Capture of the Calais coast has not ended the danger. Launching platforms with shortened German lines can still speed robots over England. Planes also can launch these robots, and have. So for Britain, the Battle of the Robomb is still not over.

Theoretically, America is not immune from the possibility of robot bombings. German U-boats still prowl up and down the Atlantic coast. If a plane can be launched from a submarine, why not robot bombs? They might have to be modified versions, since submarines aren't long enough for serving as launching platforms for the present buzz-bomb. They could certainly not come over any American seacoast area one a minute as they have over London. They might be able to launch two or three or four.

But they would only be vengeance shots involving all the inaccuracies of such bombings. The whole thing, to use a favorite word of President Roosevelt, is very "iffy." If the Nazis have adapted buzz-bombs to U-boat use, and if they are persuaded even the weakest token bombing of America would have psychological benefits, they might spend valuable manpower and resources that way. But the chances seem slight. Some authoritative sources here believe it impossible.

There is no doubt, though, that Germany is experimenting with new types of rocket bombs of larger and deadlier variety. A Stockholm report that the Nazis have some super-rocket bomb is common gossip here. Sometimes it's a 40-foot robot with "atomic explosive features." Other times it's a 40-ton projectile that can, theoretically at least, be hurled 3,000 miles. It is rumored to be as large as a Sherman tank and the destructive possibilities of having a tank full of high explosives crash in your backyard after a 3,000-mile rocket ride through space is best left to your imagination. If V-2 comes up to certain rumors, it is possible that some day one or two might come hurtling across the Atlantic. Of course, they might fall 500 to 1,000 miles off their objective.

As an Army Air Forces officer commented, "Most things are possible technically, of course, but there do seem to be immense technical difficulties involved." Germany, he explained, was no doubt working to develop rocket bombs with atomic explosive features. They'd be foolish if they didn't, he added.

These buzz-bombs or rocket bombs are the best argument that has come out of this war why, from purely selfish reasons, this country, any country, must consecrate itself to preventing another world war.—Christian Science Monitor.

Clayton Bissell and Hewlett Thebaud to the Joint Chiefs of Staff. 9 December 1944. Subject: Agreed Joint Evaluation of the Possible Existence of the V-3 Rocket and Probability of Attack against the U.S. [Franklin Delano Roosevelt Library, Hyde Park, New York. Map Room Files, Box 164, Folder Naval Aides. Files: A/16—General Correspondence]

1. The cable from Lieutenant Commander Earle, Naval Attaché, Turkey is probably propaganda and represents a plant by the Germans. There is no reliable information available of German development of a long range rocket other than the V-2.

2. The V-3 may possibly be a rocket of smaller dimensions than the V-2 with a shorter range. It would be possible to launch such a missile from specially designed or modified submarines. Attached is a sketch of a German submarine based in a southern Norwegian port showing a pair of rails extending from conning tower to the bow and terminating at a flat, rectangular surface. The purpose of this is unknown.

3. German attack from Europe of United States cities by long range rockets is deemed impossible now. Small rocket or flying bomb attacks from specially constructed submarines are considered possible. Any such action would be made with propaganda effect rather than material damage as the primary objective.

[The sketch mentioned in this document is on p. 5623. The sketch was based on photographs taken on 19 September 1944.]

INTERPRETATION REPORT Nº S 103

Appendix A

German 740 ton U boat with modified deck forward.

Scale 1"-50ft.

Dimensions :-

Length 244'
Beam 21'

Armament :-

Probably 1-37mm gun
" 4-20mm guns

Special features :-

(1) Narrowing of deck forward
(2) "Rails" on deck running from the port side of the Conning Tower forward to the narrow neck of the deck

Drawn from photographs taken by Coastal Command aircraft on 19th Sept '44
(H.Q.C.C. Ref A.2201-MIL-19th Sept 44//Q.224-Nº11)

Neg Nº 42946

Figure E.192: Allied drawing of a German submarine that was apparently modified to launch V-1 cruise missiles, based on photographs taken on 19 September 1944 [FDR Library, Map Room Files, Box 164, Folder Naval Aides. Files: A/16—General Correspondence].

Dwight Eisenhower to AGWAR. 1 November 1944. Outgoing Cable. [TNA WO 219/298; Henshall 2000, p. 165]

Following passed for what it is worth.

Special Force report quoting Danish source states U-boat will be leaving European waters shortly to launch V-1s against NEW YORK.

Date of report 30 October.

Clayton Bissell to Stockholm Military Attaché. 3 November 1944. Outgoing Cable WAR 56799. [Franklin Delano Roosevelt Library, Hyde Park, New York. Map Room Files, Box 49, Folder Rocket Bombs 1944]

Have been advised through OSS that Tykander their representative in Stockholm has received reliable information that German U boats are equipped with bomb launching platforms. Investigate and keep us fully informed.

Dwight Eisenhower to SFHQ, London. 7 November 1944. Outgoing Cable 8-65824. [TNA WO 219/298; Georg and Mehner 2004, p. 209.]

War Department G-2 have requested further evidence and any other confirmation of Special Force report of 30 October quoting Danish source who stated U boat would be leaving European waters shortly to launch V 13 [sic: V-1s] against NEW YORK. Most grateful your assistance including re evaluation source and report if possible.

Dwight Eisenhower to AGWAR. 13 November 1944. Outgoing Cable S-66672. [TNA WO 219/298; Henshall 2000, p. 164]

Special Force Headquarters reports same source reported 7 November that he believed 4 U-Boats were to be used in operation against NEW YORK operating from BERGEN but course and rate unknown. Special Force Headquarters grades source as (usually reliable) but comments that no other confirmation to possibility of such action received from BERGEN or elsewhere.

U-Boat Aimed V-Bomb Here, Army Paper Says. *New York Times.* 15 May 1945 p. 10.

A German submarine tried to V-bomb New York last election day, presumably with a jet-propelled or rocket-propelled weapon, the Army newspaper Stars and Stripes reported tonight, quoting "sources considered reliable."

It was reported that the bomb was launched from the deck of a U-boat lying off the coast and that it fell short or was knocked down by fighter planes patrolling as a screen against any such projectiles. The Stars and Stripes said that "operators" at Mitchel Field were quoted as having said that it was determined that the bomb fell into the sea.

The paper recalled that last Nov. 8, the day after the Presidential election, the Army and Navy in a joint statement said that a V-bomb attack on the United States was entirely possible.

A Navy spokesman in Washington said that the report of the submarine attack was without foundation, The United Press reported.

An official of the bomb squad of New York's Police Department said last night that the squad had no knowledge of an attempted bombing of New York last Nov. 7 by the Germans.

"Undoubtedly, if a robot bomb had been launched at New York from a U-boat, as reported, and had neared its objective, we would have been informed," the spokesman said.

[The original version of this story appeared as: U-Boat Aimed V-Bomb at New York, *Stars and Stripes*, 14 May 1945. Considering that the report came from the U.S. Army's own newspaper and sources that they considered reliable, the subsequent denials by the U.S. Navy spokesman and New York bomb squad do not seem very convincing.

If the incident actually occurred, can it be clarified if the weapon was a sub-launched V-1 cruise missile or something else? If the weapon fell into the sea, was it ever located?

Was the warhead a conventional explosive, or a chemical, biological, or nuclear weapon? A V-1 strike on a U.S. city with only a conventional warhead would have done relatively little damage and would have had no strategic military value. For evidence of modified V-1 missiles that could have delivered weapons of mass destruction, see pp. 1841 and 4896–4897, as well as Henshall 2000, pp. 129–130.

U.S. fears of a submarine-launched missile strike on East Coast cities continued in spring 1945. From April to the end of the war in Europe, the U.S. Navy conducted Operation Teardrop to intercept a number of German submarines approaching the United States. Were any of those submarines armed with something more than has been acknowledged in the official history books? All relevant archival files need to be located and declassified.]

S. McClintic, Headquarters U.S. Strategic Air Forces in Europe, Office of the Director of Intelligence, to George C. McDonald. 6 January 1945. Big Ben (Rockets). [AFHRA A5734 electronic version pp. 1093]

[...] Again we receive reports of ships being constructed for the launching of flying bombs, this one a 6000 ton boat at Hamburg, and another report that the shipyards, DEUTSCHE WERFT BETRIEB FINKENWERDER are putting ramps on the decks. [...]

J. Edgar Hoover to Harry Hopkins. 8 January 1945. [Franklin Delano Roosevelt Library, Hyde Park, New York. Official File 10b. Box 20. Folder OF 10-b, Justice Department, FBI Reports 1944–45. 2597–2618]

During the interrogation of William Curtis Colepaugh, the enemy agent who was landed by German submarine off the coast of Frenchman's Bay, Maine, on the night of November 29, 1944, several interesting features have arisen concerning his submarine trip to the United States. [...]

Upon arrival at Kristianson, Norway, on the U-1230 he learned that the U-1231 and the U-1233, both submarines of the same type as the U-1230, had just completed some sort of test at Kristianson, Norway.

Colepaugh has said that members of the crew of the U-1230 indicated in conversation that they had observed at one of the submarine ports near Danzig some members of other submarine crews practicing in groups with equipment of a rocket or gun type on the deck and these crew members presumed this equipment would be used against the United States. He said the crew members he talked with were pretty definite about this stating that the submarines would proceed to within 100 or 200 miles of the United States and then fire these rockets. Colepaugh pointed out, however, that the crew members on the U-1230 had no knowledge of the use of this rocket and based their presumption only on what they had observed at the submarine port near Danzig.

Robot Bomb Attacks Here Held 'Probable' by Admiral. *New York Times*, 9 January 1945, pp. 1, 6.

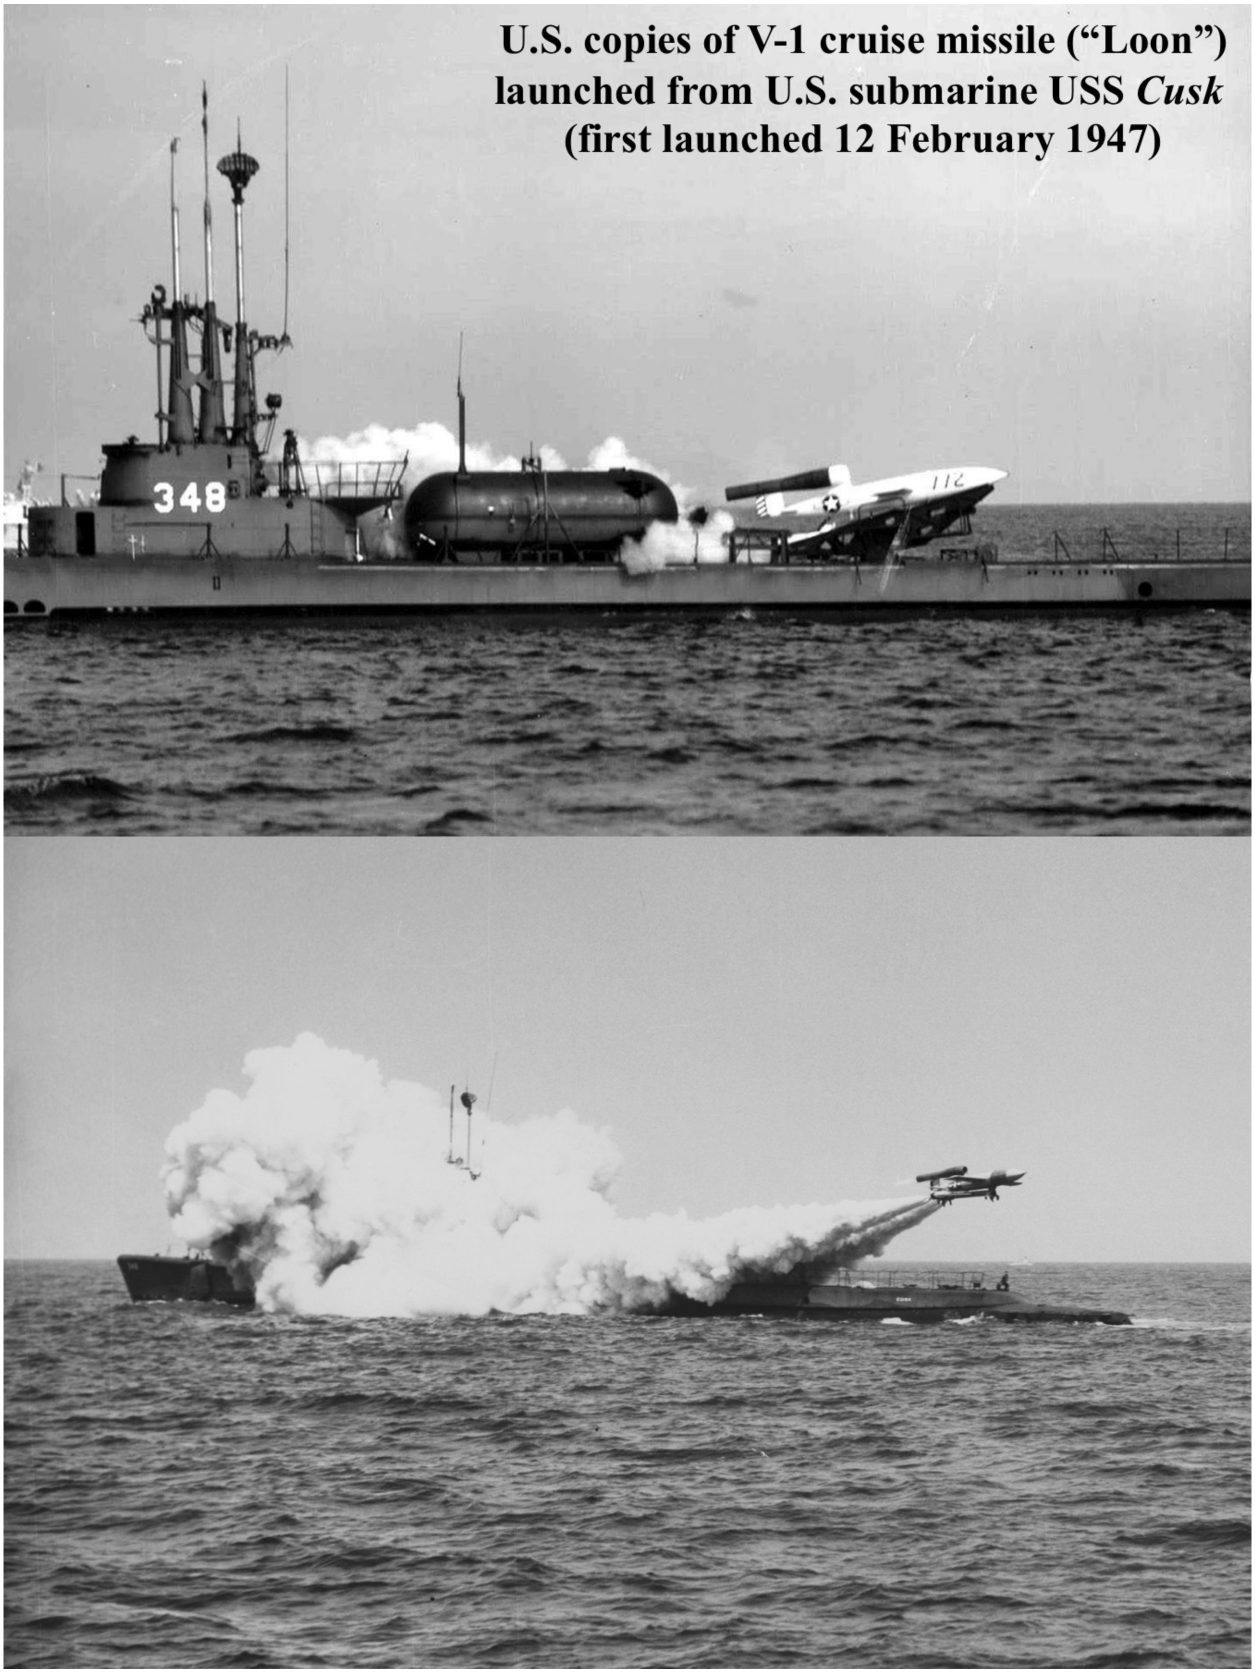
AN EAST COAST PORT, Jan. 8—A strategically futile attack on New York or Washington by robot bombs within thirty to sixty days was described today as not only "possible but probable" by Admiral Jonas H. Ingram, new Commander in Chief of the Atlantic Fleet, whose command stretches from the Arctic to the Falkland Islands. [...]

"And we know very definitely that there are three ways in which he might get robot bombs within range of either city. He might sneak a half dozen submarines off the coast. He might launch robots from the long-range planes we know he has. Or he might sneak a surface ship, disguised as a neutral, within range." [...]

[See also: Officials Silent on Robot Threat/London Paper Predicts Attack. *New York Times*, 10 January 1945, p. 7.]

H. H. Smith, N. W. Dickson, V. P. Kovac, and E. H. Bennett. German Developments in the Guided Missile Field. 10 January 1946. Project 2874. [NARA RG 319, Entry NM3-82, Box 2879, Folder Project 2784]

Two further developments of the V-1 program were an attempt to launch the missile from a ramp on the deck of a submarine and a project for a piloted V-1. In the first case a ramp was constructed though never used; it is believed that this was intended for attacks against coastal towns and defenses on the Eastern seaboard of the U.S.A. In the second instance, several models were constructed though, as far as is known, none were ever used. It was intended that the pilot should fly the missile to within a short range of the target, set the controls and then jump out.



U.S. copies of V-1 cruise missile ("Loon")
launched from U.S. submarine USS *Cusk*
(first launched 12 February 1947)
348
112

Figure E.193: Loon, a U.S. copy of the V-1 cruise missile, was launched from the USS *Cusk* submarine, based on wartime German developments and implemented by German-speaking scientists at Point Mugu Naval Air Missile Test Center.

Walter Dornberger. 1958. *V-2: The Nazi Rocket Weapon.* New York: Viking. pp. 231–237.

In the autumn of 1943 Lafferenz, of the German Labour Front, paid me a visit and told me that he had proved by practical experiment that, contrary to predictions by the Navy, a submarine could take in tow as many as three cigar-shaped, submersible containers 100 feet long. He urged us to examine the possibility of launching our A4 from these floats. It it could be done we should be able to bombard big military objectives overseas across hundreds of miles of water.

The problem interested us. In the summer of 1942 we had already experimented near the Greifswald Oie with launching solid-propellant rockets from a submarine. It had been Steinhoff's idea at the time. He had noticed the heavy projectiles developed by my department, the solid rockets for the *Nebelwerfer*[1] detachments. His brother was a submarine commander and had a long voyage to make very shortly. We were talking about it and suddenly had an idea. Rockets worked under water; how would it be if we could accommodate 20 or 30 of them, with a charge of inflammable oil or high explosive and ready for launching, aboard a submarine? The submarine could then submerge, approach to within 2 miles of the shore and discharge the rockets under water against oil tank installations on the coast. The petrol and oil tanks would certainly be set on fire by the oil which would ignite on impact.

[1] The *Nebelwerfer* was a weapon roughly equivalent to a trench mortar, in which rocket-propelled shells (originally intended to lay smoke-screens, etc.) were fired from a multi-barrelled launcher.

At Swinemünde improvised launching frames were erected on the deck of the submarine by workmen from Peenemünde and a few days later several salvos were launched from a depth of 30–50 feet. Nothing whatever could be felt of the launchings in the submerged submarine. The trajectory was capital, in fact dispersion was reduced and range slightly increased by the improved initial motion of the missiles through the water. A staggering sight it was when those 20 heavy solid rockets suddenly rose, with a rush and roar, from the calm waters of the Baltic. This improvisation could have been put to immediate and successful use against the enemy, but the Naval Weapons Department, the competent authority for all naval weapon development, would not approve it, though it had served its purpose perfectly. The Navy itself insisted on doing the designing. Months, a whole year went by. [...]

Peenemünde made a thorough study of the problem set by Lafferenz. A submarine could tow three floats weighing about 500 tons for 30 days at an average speed of 12 knots. Their submerging and surfacing could be controlled from the submarine. An A4 and the necessary quantities of propellants could be accommodated without difficulty.

On arrival at the launching point the floats could be partially flooded so that they stood upright in the water. The top hatch could then be opened and the A4, erect upon its gyro-stabilized platform, after being fueled, prepared for launching and laterally adjusted, could be discharged.

We did not expect any construction difficulties that could not be overcome, but work on the subject had been temporarily suspended because of the A4 troubles. Now, at the end of 1944, it was resumed. By the middle of December a full memorandum was being prepared on the preliminary experiments, and we were getting to work on the first draft designs. The evacuation of Peenemünde put paid once for all to a not unpromising project.

[Dornberger mentioned several wartime projects that are illustrated on the following pages:

- In May 1942, there was a series of successful tests to launch small Nebelwerfer rockets from a submerged submarine (U-511). Those tests were documented in a June 1942 report [Bundesarchiv Militärarchiv Freiburg RH 8/369]. See pp. 5631–5639.

- Based on those successful initial tests, during 1942–1945, the German Navy sponsored the development of a whole series of increasingly sophisticated short-range rockets that could be launched from a submerged submarine. Those rockets were successfully demonstrated at Toplitz See, Austria. The rockets and testing equipment were all destroyed at the end of the war as American forces approached. After the war, though, U.S. Navy investigators interrogated several of the engineers who were involved in the project and wrote a report about their work [NavTecMisEu 500-45]. See pp. 5640–5645.

- Also based on the 1942 tests and the proposal by Lafferenz, engineers from Peenemünde began working on the "Prüfstand XII" project to transport and launch A-4 (V-2) rockets from specially designed underwater cargo containers that could be towed by submarines. For examples from a large collection of 1944 design drawings [Bundesarchiv Militärarchiv Freiburg RH 8/4067K], see pp. 5646–5654. Although in Dornberger's postwar public statements he said that nothing ever came of the project, it is unclear how far the project may have actually progressed. There were reports that at least one Prüfstand XII unit may have been constructed and tested before the end of the war.

- As described in earlier documents (pp. 5618–5627), there were also wartime programs to launch modified V-1 cruise missiles from German submarines.

These and other wartime German projects were continued in other countries after the war, with the aid of German-speaking scientists and captured German hardware and plans:

- Beginning in February 1947, Loon missiles, U.S. copies of German V-1 cruise missiles [Quigg 2014], were launched from the USS *Cusk* submarine, based on wartime German developments and implemented by German-speaking scientists at Point Mugu Naval Air Missile Test Center. See p. 5627.

- As part of Operation Sandy, the U.S. Navy launched an A-4 (V-2) rocket from the deck of the USS Midway on 6 September 1947, demonstrating that an A-4 rocket could indeed be transported and launched at sea (p. 5661).

- German-speaking scientists and technologies were used to develop a series of more advanced U.S. cruise missiles beginning in the late 1940s (pp. 1850–1854).

- Wernher von Braun's team was directly involved in developing Jupiter, a liquid propellant ballistic missile designed to be launched from submarines (but ultimately only deployed on land; see p. 1897).

- German-speaking scientists were deeply involved in the development of U.S. solid propellant submarine-launched ballistic missiles (SLBMs) in ways that have never been fully disclosed to the public (pp. 1902–1904 and 5700–5736).

- In 1962, Robert Truax at Aerojet proposed to greatly scale up the "Prüfstand XII" approach to create the Sea Dragon, a sea-launched rocket that would have been larger than even a Saturn V (p. 5655).

- The Soviet Union also investigated versions of the "Prüfstand XII" approach as part of its postwar Golem program to develop SLBMs.[7]

- The first deployed Soviet SLBM, the R-11FM Zemlya (SS-1B SCUD-A), was directly based on the German Wasserfall (first launched in 1944). Like the Wasserfall, it used storable liquid propellants. The R-11FM was first launched from a submarine on 16 September 1955. See pp. 1898–1899.

- Later generations of Soviet SLBMs, such as the R-13 (SS-N-4, first launched in 1959) and R-21 (SS-N-5, first launched in 1962) were scaled up from the R-11FM and again were directly based on German-developed technologies and propellants (p. 1900).

- German-speaking scientists and technologies likely also had a great impact on the postwar submarine-launched missile programs of other countries (e.g., p. 5660).]

Im Anschluss an dieses Schiessen wurde zwischen dem 2. Admiral der U-Boote und der HAP abgesprochen, dass die nächsten Schiessversuche von U-Boot U 511 stattfinden sollen, ~~und dieses U-Boot~~ nach Abschluss der praktischen Übung und Erledigung des Abhorchens der Sondereinbauten bei dem U-Bootstützpunkt Stettin, ~~durchgeführt werden sollen~~. Diese Einbauten wurden in der Zeit vom 31.5. - 4.6. in Stettin durchgeführt. Es wurden 4 Abschussgestelle für insgesamt 16 30 cm Wk Spr 42 hinter dem Turm des U- Bootes so angebracht, dass die Schussrichtung der an Backbord auf den Torpedotransportschienen montierten Gestelle nach Steuerbord und die auf den Transportschienen steuerbordseitig angebrachten Abschussgestelle eine unter 90° zur Bootslängsachse ausgerichtete Schussrichtung nach Backbord ergab. Die Zündanlage wurde im Turm des U- Bootes angebracht und durch die vorhandene wasserdichte Durchführung zunächst am Turm herunter und dann unter Deck bis zu den Abschussgestellen geführt. An den Durchführungen am Turm befindet sich jeweils ein Verteilerkasten, ausserdem wurden durch die Oderwerft Stettin jeweils in der Höhe des Geschosses druckwasserdichte doppelpolige Steckdosen verlegt.

Fritz Hahn. 1998. *Waffen und Geheimwaffen des deutschen Heeres 1933-1945.* 3rd ed. Bonn: Bernard & Graefe. p. 172

Das System konnte natürlich nicht für die große A 4-Fernrakete angewendet werden. Aber auch für einen derartigen, zum Beschuß der amerikanischen Küste geplanten Einsatz fand man eine Lösung. U-Boote sollten die Rakete in einem 500 t großen Behälter von 32 170 mm Länge und 5500 mm Durchmesser in die Nähe der gegnerischen Küste schleppen. Dort wollte man das Heck dieses Behälters so weit fluten, daß er, nun senkrecht stehend, etwa 5 m aus dem Wasser herausstand. Mit den im Behälter vorhandenen Treibstoffen wollte man dann die Rakete auftanken. Kreiselstabilisiert hätte das sicherlich eine ausreichende Platform für den vom U-Boot durch Funk ausgelösten Abschuß ergeben. Ein Problem wäre der Verlust an Sauerstoff durch die Verdunstung geworden, denn das U-Boot wäre bei 12 sm etwa 30 Tage unterwegs gewesen.

Der Unterwasserschlepp wurde mit U 1063 erprobt und zeigte kaum Probleme. Für den Einsatz waren die Elektro-Boote vom Typ XXI vorgesehen. Die ersten Besprechungen zur Lösung der technischen Fragen führte Dr. Dickmann von der mit dem Bau beauftragten *Stettiner Vulkan-Werft* am 9. Dezember 1944—die drei begonnen Muster sind aber nicht mehr fertig geworden.

Of course, this system [small sub-launched rockets] could not be used for the large A-4 long-range rocket. But a solution was also found for such an operation planned for the American coast. Submarines were to tow the rocket in a 500 ton container of 32.17 m length and 5.5 m diameter near the enemy coast. There they wanted to flood the stern of this container so far that it, then standing vertically, protruded about 5 m out of the water. They wanted to fuel the rocket with the propellant contained in tanks. Stabilized by gyroscopes, this would surely have provided a sufficient platform for the launch controlled by radio from the submarine. A problem would have been the loss of oxygen by the evaporation, because the submarine would have required 12 sm or about 30 days for the voyage.

The underwater towing was tested with U-1063 and showed hardly any problems. The electric boats of type XXI were intended for use. The first discussions for the solution of the technical questions were held by Dr. Dickmann of the *Stettiner Vulkan-Werft* on 9 December 1944—the three started samples were not finished anymore.

[Fritz Hahn did not cite sources for the information in his books, but he was very closely connected to people who were involved in advanced military projects.

It is true that cryogenic liquid oxygen, the usual oxidizer for A-4 rockets, would have been difficult to keep from evaporating during a long sea voyage. However, wartime Germany developed storable, noncryogenic oxidizers such as nitrogen tetroxide (N_2O_4) and inhibited red fuming nitric acid (IRFNA) that could have been used instead of liquid oxygen in an A-4 rocket.]

Deutsches U-Boot-Museum. U 511 and Missiles: U 511, U 1063 and plans for U-boats armed with seabased missiles. [**https://dubm.de/u-511-and-missiles/?lang=en**]

Also, the vision, born after the US entered the war, to fire at the US an advanced multiple stage version of the V-2 (the project A-9/A-10 with ranges of more than 5,000 km) gained some momentum following a proposal brought forward by a director of the "Deutsch Arbeitsfront" (= German Labor Front, a sort of national socialistic controlled trade union), Otto Lafferenz. After a visit of the facilities at Peenemünde and a meeting with the Military Commander, Major General Walter Dornberger, in the Autumn of 1943, he proposed to develop floating containers to accommodate V-2s and to tow them by U-boats before the US Eastern coast, to fire at New York and other area targets utilizing on their range up to 300 km. This arms project now called "Lafferenz-Project" (somewhat irritating, various authors in historic writing use other project names such as "Schwimmweste" = "Life Vest", "Apparat F", or "Prüfstand XII" = "Test Stand XII") was consequently developed further, and as a first step a floating container was invented able to transport and launch, to be towed by U-boats. The end status of the concept envisaged an operation, where up to three containers were towed simultaneously by U-boats across the Atlantic Ocean, to be erected in some distance before the coasts into a vertical firing position by partial flooding—and to launch the V-2s.

For that the Weapons Test Command No. 10 at Stetting developed a container with a length of about 32 meters, a diameter of about 5.5 meters and a displacement of some 300 tons, to be constructed at the Vulcan shipyard at Stettin. At the turn of 1944 to 1945 successful towing trials were actually executed using the type VII C/41 U-boat U 1063, which went through its basic and combat readiness training with the 5th U-boat (Training) Flotilla at Stetting at that time, after it had been commissioned on 08 July 1944 at the end of its construction by the Germania shipyard at Kiel. Following its training period until the end of February 1945 the U-boats came frontal unit as of 01 May 1945 at Bergen, Norway.

[Most books say that the Prüfstand XII project was only a paper design that was briefly considered and never progressed further. However, from the above and similar reports, it sounds as if at least one Prüfstand XII unit may have actually been constructed and tested. It is unclear how far the project may have actually progressed by the end of the war].

Joseph Mark Scalia. 2000. ***Germany's Last Mission to Japan: The Failed Voyage of U-234.*** **Annapolis, Maryland: Naval Institute Press. p. 84.**

American naval intelligence officials were determined to press Kessler for as much information as possible on the state of Germany's U-boat capability. While the Wehrmacht and the Luftwaffe had been virtually destroyed by the time of Germany's capitulation, Dönitz's submarine corps, rejuvenated by the potential of the revolutionary electric U-boats, remained a considerable threat. As a result, the export of German submarine technology to Japan constituted an immediate threat to the U.S. Navy. A major area of concern was Germany's alleged development of submarine ballistic-missile technology. Reports of the submerged launching of missiles prompted the ONI to question Kessler regarding the rumor of U-boats, stationed in Norway, that were able to launch a V-2 rocket while submerged.

Albert Ducrocq. 1947. *Les Armes Secrètes Allemandes.* Paris: Berger-Levrault. pp. 161–163.

D'ailleurs, outre le bombardement par A-9, les Allemands voulaient entreprendre le bombardement direct des côtes américaines au moyen de V-2 lancées par des sous-marins. C'était leur deuxième arme nouvelle contre l'Amérique. Elle devait entrer en action en même temps que la A-9, c'est-à-dire au début de l'été 1945...

Les V-2 amphibies

L'idée d'utiliser les sous-marins pour transporter des V-2 remonte à 1942. Au moment où la fabrication industrielle des V-2 était entreprise, l'entourage d'Hitler avait porté beaucoup d'attention au projet de V-2 amphibies que venait d'élaborer l'équipe de von Braun. Mais les travaux d'aménagement pratiques furent longs et fastidieux et ne purent être menés à bonne fin qu'en 1944, date à laquelle le premier sous-marin capable de lancer des V-2 fut effectivement construit. [...]

Il apparait que les mises au point devaient être complètement terminées au moment de l'effondrement allemand de mail 1945 et que les Allemands s'apprêtaient à continuer les essais sur l'Amérique elle-même. Quelle aurait été la zone menacée? Il semble que la portée de la V-2 amphibie, du moins dans l'état où les recherches expérimentales du lac Toplitz ont laissé la question, était très nettement inférieure à celle de la V-2 ordinaire, de l'ordre de 150 à 200 kilomètres seulement. Inutile d'ajouter que c'eût quand même été largement suffisant pour le bombardement des port américains: Boston, New-York, Philadelphie, Baltimore, Charleston, etc. Évidemment plus la profondeur à laquelle opéraient les sous-marins était grande, plus la portée était réduite. Nous avons vu que les derniers sous-marins allemands pouvaient voguer à 300 mètres de profondeur; il ne semble toutefois pas qu'un lancer de V-2 amphibies ait pu être envisagé à partir d'une telle profondeur.

What is more, in addition to A-9 bombing, the Germans wanted to undertake direct bombing of the American coastline using submarine-launched V-2s. This was their second new weapon against America. It was to come into action at the same time as the A-9, i.e. in early summer 1945...

Amphibious V-2s

The idea of using submarines to transport V-2s dates back to 1942. At the same time as industrial production of the V-2s was being undertaken, Hitler's entourage had paid close attention to the amphibious V-2 project that von Braun's team had just drawn up. But the practical development work was long and tedious, and was not completed until 1944, when the first submarine capable of launching V-2s was actually built. [...]

It transpires that the tests were to be completed by the time of the German collapse in 1945, and that the Germans were preparing to continue the tests on America itself. What area would have been threatened? It seems that the range of the amphibious V-2, at least in the state left by the experimental research at Lake Toplitz, was considerably less than that of the ordinary V-2, of the order of only 150 to 200 kilometers. Needless to say, this would still have been more than sufficient for bombing American ports such as Boston, New York, Philadelphia, Baltimore, and Charleston. Obviously, the greater the depth at which the submarines operated, the shorter their range. We have seen that the latest German submarines could operate at a depth of 300 meters; however, it doesn't seem that an amphibious V-2 launch could have been envisaged from such a depth.

Quoi qu'il en soit, la menace eût été extrêmement sérieuse pour la côte américaine puisque, d'une part, une fois la V-2 lancée, il a jusqu'ici été impossible de se défendre contre elle, et que, d'autre part, la détection et la lutte contre les nouveaux sous-marins allemands n'eût pas été une petite affaire, indépendamment de l'auto-guidage de la V-2 par détection de rayons infra-rouges ou autres. [...]

C'est vraisemblablement à partir du mois de juin 1945 que l'Allemagne pensait attaquer le territoire américain. Notons-le: alors que la mise en action d'autres armes secrètes, comme les bombes volantes et les nouveaux avions-fusées, était littéralement imminente, cette menace contre les États-Unis doit être située à six semaines ou deux mois après la date qui marqua l'effondrement du Reich. On nous permettra de la trouver pratiquement tout aussi dangereuse, d'autant plus que les V-2 amphibies, elles aussi, auraient très bien pu transporter des bombes atomiques.

In any case, the threat would have been extremely serious for the American coast, since, on the one hand, once the V-2 had been launched, it has so far been impossible to defend against it, and, on the other hand, detecting and combating the new German submarines would have been no small matter, independently of the V-2's self-guidance by infra-red ray detection or other means. [...]

Germany was probably thinking of attacking American territory beginning in June 1945. It should be noted that while the use of other secret weapons, such as flying bombs and new rocket planes, was literally imminent, this threat to the United States must be located six weeks or two months after the date of the collapse of the Reich. We are allowed to consider it almost as dangerous, especially since the amphibious V-2s, too, could very well have carried atomic bombs.

[Albert Ducrocq (1921–2001) was a French scientist and science writer who was involved in the French investigations of German science and German scientists near the end of the war and after the war. He would have had enormous insight into German scientific plans and capabilities.

Based on his personal experience and his sources, Ducrocq stated that Germany possessed atomic bombs and planned to deliver them via submarine-launched missiles and other means, with a massive, nearly simultaneous attack on many Allied targets to be carried out within a matter of weeks if the war in Europe had not ended when it did. For independent confirmation, see pp. 4549–4550, 4587, 4621, 4627–4665, 4679–4681, 4766, 5038, 5454–5466.

For more information from Ducrocq, see pp. 5218, 5380, 5666.]

Raketen aus dem Ozean: Roboterhände helfen starten: Neue U-Boot-Kampfmittel. *Abendpost* (Frankfurt) 14 April 1950 p. 2.

In der für die Zivilluftschifffahrt gesperrten Morecambe-Bucht an der Westküste Englands arbeiten englische und deutsche Fachleute an der Entwicklung der Waffen des zukünftigen Seekrieges. Ihr Ziel: schnelle, weitreichende, fast unbegrenzt tauchfähige U-Kreuzer, die zur Abwehr feindlicher U-Boote, vor allem aber als Abschluß-Basen für ferngelenkte Raketen eingesetzt werden können.

Was es für die Techniker schon eine schwierige Aufgabe, auf den fischförmigen schmalen Rumpf eines U-Bootes die breite Plattform für den Abschuß einer V 2 zu montieren, so schien es zunächst fast unmöglich, das Problem des Abschusses von Raketen unter Wasser zu lösen. Deutsche Pläne, die nach der Kapitulation von englischen Truppen gefunden wurden, gaben der britischen Admiralität die entscheidenden Anregungen für die nun in der Morecambe-Bucht erprobten Geschosse.

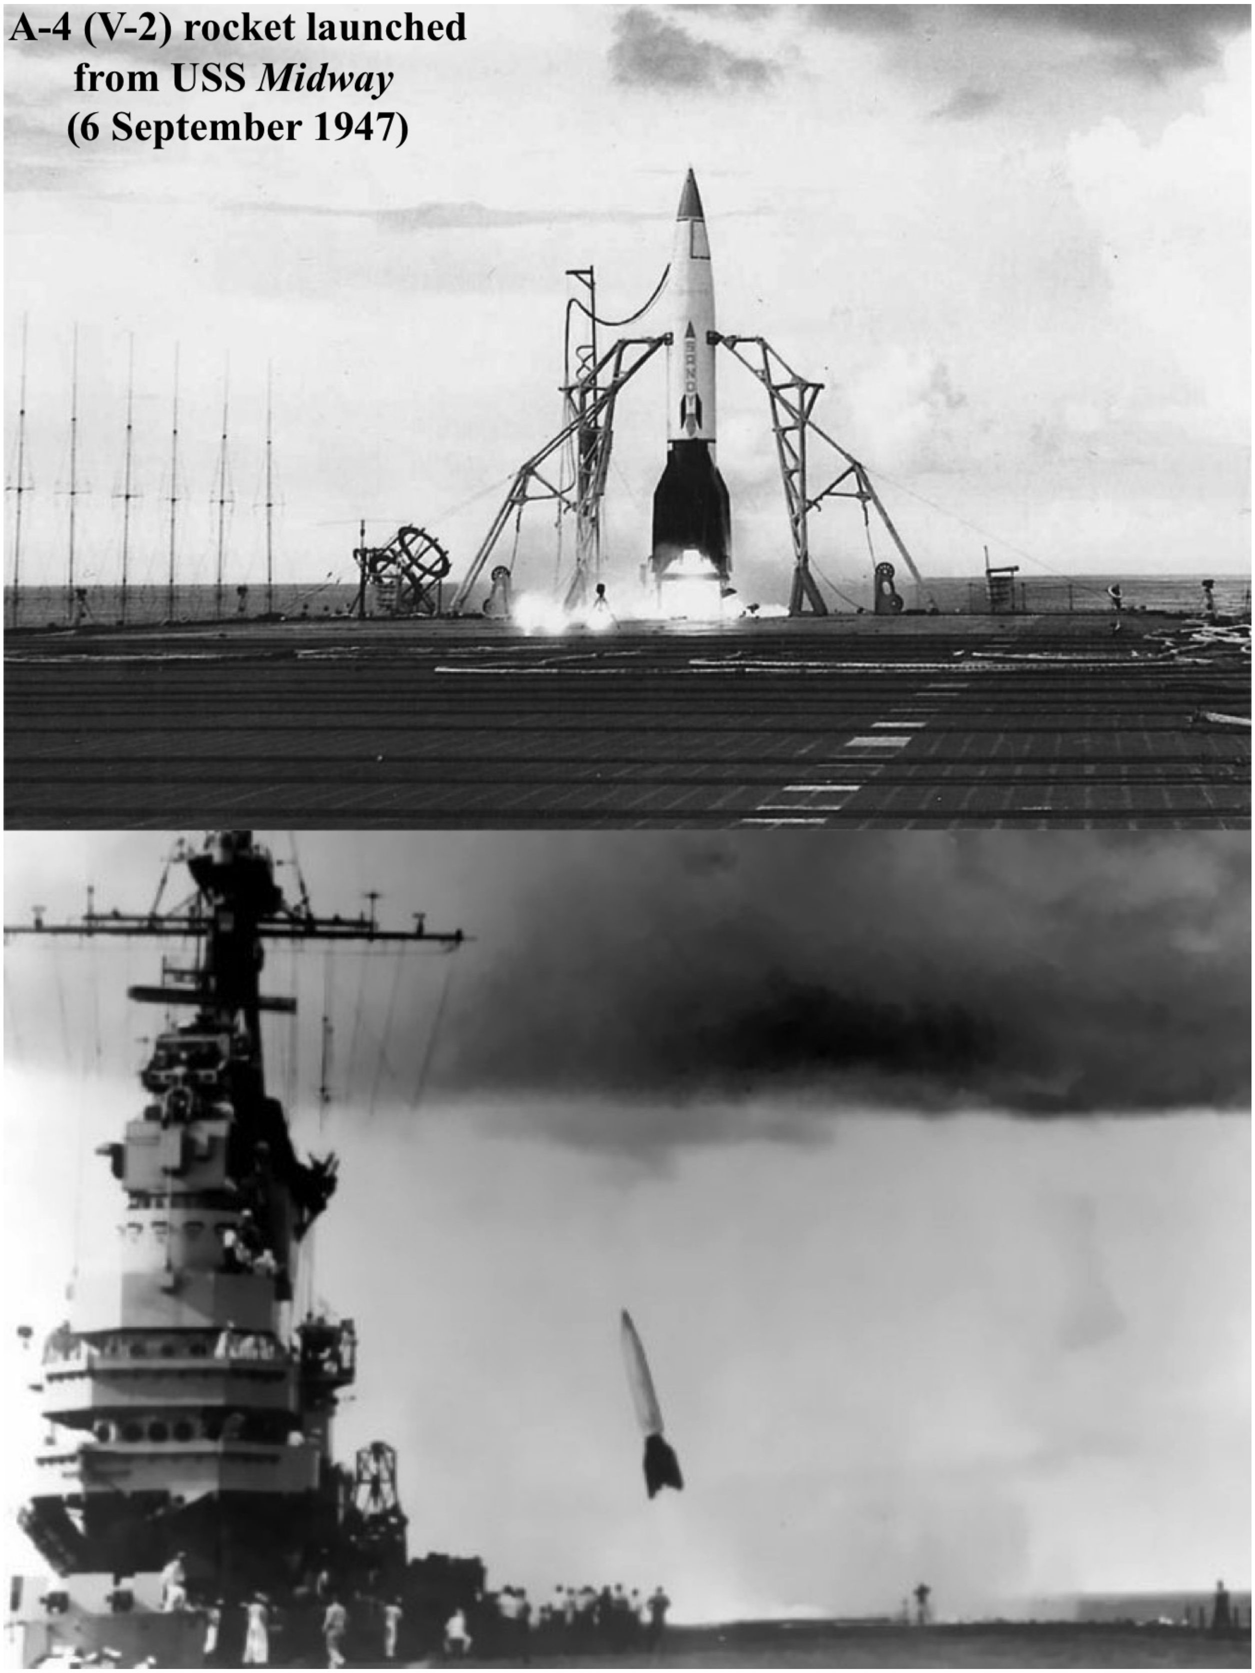
Die neuen Raketen werden in zwei Phasen abgeschossen. Wie ein Torpedo gelangt das riesige Geschoß von der Plattform des beliebig tief getauchten U-Bootes mit Hilfe von Preßluft an die Wasseroberfläche. Hier geschieht das Wunder: im Augenblick des Auftauchens treten von Präzisions-Uhrwerken angetriebene Roboterhände in Tätigkeit. Sie bauen aus einem Gitterwerk von Leichtmetallplatten, die aus dem Schwanzteil der Rakete herausgeschleudert werden, eine Art schwimmende Abschußbasis. Auf die Sekunde genau mit der Fertigstellung der Plattform beginnen die Rückstoßkammern der Rakete zu arbeiten. Mit einem feurigen Schweif steigt der unheimliche, wassergeborene Komet in die Höhe. Zugleich mit der Rakete wird eine Tele-Boje mit kompletter Radareinrichtung an die Oberfläche geschickt, die nun als Zwischenstation die Richtungsbefehle des getauchten U-Bootes an die Rakete weitergibt. [...]

In Morecambe Bay on the west coast of England, which is closed to civil aviation, English and German experts are working on the development of weapons for the future naval war. Their goal: fast, long-range, almost unlimited submersible U-cruisers, which can be used to defend against enemy submarines, but above all as bases for remote-controlled missiles.

What was already a difficult task for the technicians to mount the wide platform for launching a V-2 on the fish-shaped narrow hull of a submarine, at first it seemed almost impossible to solve the problem of launching rockets under water. German plans, which were found after the surrender of English troops, gave the British admiralty the decisive suggestions for the projectiles now tested in Morecambe Bay.

The new missiles will be launched in two phases. Like a torpedo, the huge projectile is launched from the platform of the submarine submerged to any depth with the aid of compressed air to the surface of the water. This is where the miracle happens: at the moment of emergence, robotic hands driven by precision clockworks start working. They build a kind of floating launch base from a lattice of light metal plates which are ejected from the tail of the rocket. The recoil chambers of the rocket start to work exactly to the second when the platform is completed. With a fiery tail, the eerie, water-born comet rises. At the same time as the rocket, a tele-buoy with complete radar equipment is sent to the surface, which now transmits the directional commands of the submerged submarine to the rocket as an intermediate station. [...]

[This article describes a wartime alternative to the Prüfstand XII approach, and also serves as an example of how German plans and German-speaking scientists played critical roles in other countries' postwar programs to develop submarine-launched missiles.]



A-4 (V-2) rocket launched
from USS *Midway*
(6 September 1947)

Figure E.219: As part of Operation Sandy, the U.S. Navy launched an A-4 (V-2) rocket from the deck of the USS Midway on 6 September 1947 [http://www.cv41.org/photos/gallery/main.php?g2_itemId=17451].

[Although solid propellant rockets have lower exhaust velocities than liquid propellant rockets, they can generally be stored for years without degradation. Therefore, they are primarily used for military rockets and "off-the-shelf" boosters that can be strapped to the side of the first stage of a spacecraft launch vehicle. For submarine-launched rockets, where it is necessary to be able to store the rockets stably and safely for years and yet fire them on very short notice, solid propellants are highly preferable to liquid propellants.

In a solid propellant rocket, the propellant burns along its exposed surfaces, releasing hot exhaust gases through the nozzle unless the thrust termination port is opened (see p. 1905). Different solid propellant grain designs have different cross-sectional patterns of exposed surfaces such that the exposed surface area and hence the thrust changes in some desired way (increasing, remaining constant, or decreasing) as the rocket burns.

During World War II, a number of nearly forgotten German-speaking chemists and engineers (such as those shown on pp. 1906–1910), successfully developed and demonstrated advanced solid propellant rockets, including for example:

- The Rochen ammonium perchlorate/polybutadiene short-range missile, first fired in 1944 (p. 1911).
- The Rheintochter two-stage surface-to-air missile, first launched in 1943 (pp. 1912 and 5663).
- The Rheinbote four-stage long-range rocket, first launched in 1943 (pp. 1913 and 5663).
- The V-101, an ammonium perchlorate/polybutadiene propelled, 140-ton, 30-meter-tall, long-range ballistic missile that was under development when the war ended (p. 1914).

Key German innovations of that solid propellant rocket technology included:

1. Ammonium perchlorate oxidizer [BIOS 31; BIOS 571].
2. Polybutadiene "buna" synthetic rubber in the propellant to act as both fuel and binder [BIOS 31; BIOS 571].
3. Plasticizers to enable the propellant to be molded into any desired shape, to adhere tightly to metal walls, and not to be prone to crumbling or brittleness [BIOS 31; BIOS 571].
4. Powdered aluminum as a fuel additive to improve performance [BIOS 27; BIOS 31; BIOS 100; BIOS 477; BIOS 1261; FIAT 1035; HEC 2434; HEC 2485; HEC 2487; NavTecMisEu 327-45].
5. Various grain designs for the combustion surface inside the propellant to give the desired variation of thrust with time [Benecke and Quick 1957, pp. 253–255; Klein 1977; BIOS 31; BIOS 1110; NavTecMisEu 327-45].

This wartime German technology became the basis for large postwar solid propellant rockets, including satellite launch vehicles such as the U.S. Scout; strap-on solid rocket boosters such as those used with the U.S. Space Shuttle, Titan, and Delta rockets; submarine-launched ballistic missiles such as the U.S. Polaris, Poseidon, and Trident; and solid propellant land-based ballistic missiles such as the U.S. Minuteman and MX.]

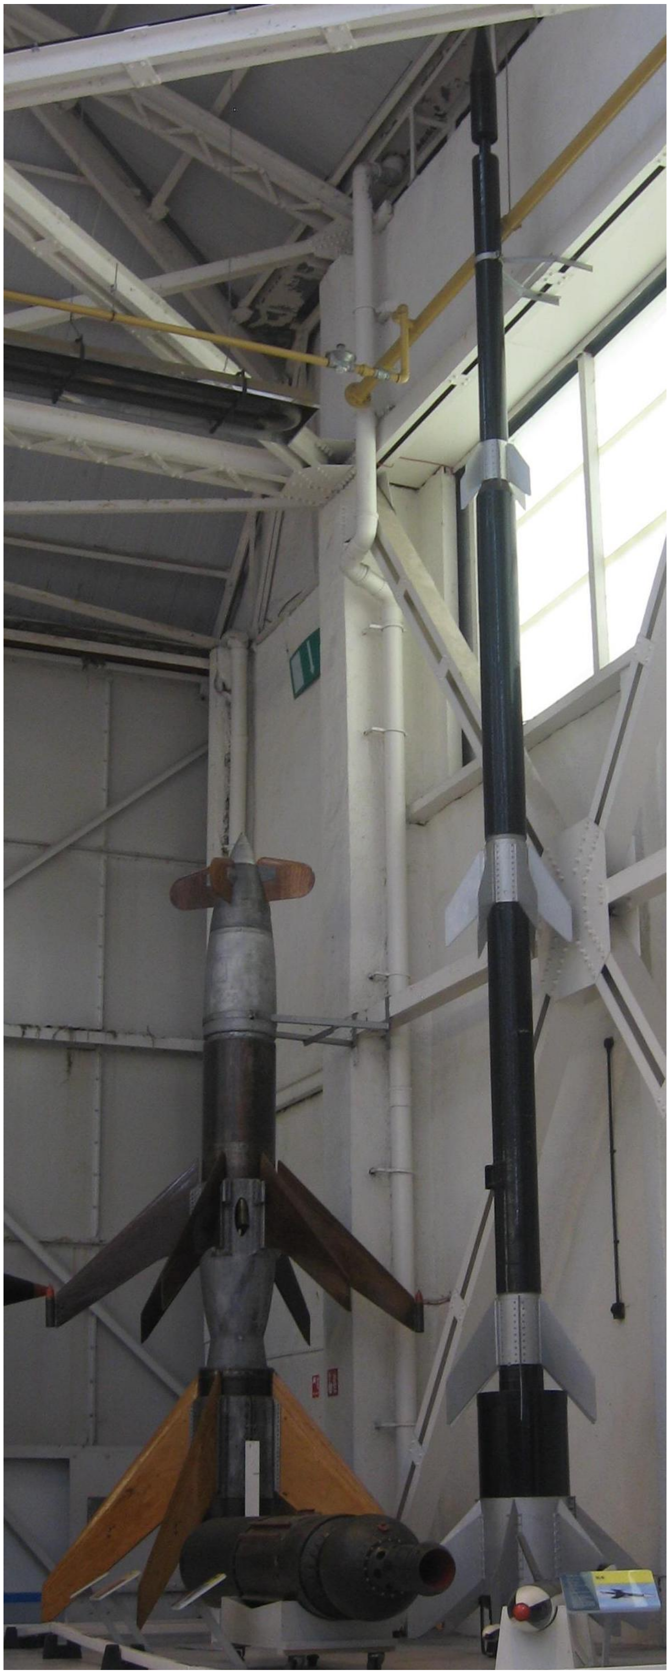


Figure E.220: Rheintochter R1 two-stage solid propellant rocket (left), partial Rheintochter R3 strap-on solid propellant booster (horizontal, center), and Rheinbote four-stage solid propellant rocket (right).

Nazis Use ‘AA’ Rockets in Italy. *New York Times*, 16 January 1945, p. 12.

ROME, Jan. 15 (Reuter)—The Germans are using anti-aircraft rockets for the first time in northern Italy, it was reported today. Havoc pilots of the Mediterranean Allied Air Force said on returning to bases that two volleys of twenty-five rockets each were fired at them when they were attacking enemy motor transport and communications in the Genoa area.

NavTecMisEu 373-45. ***German War Research vs Air Superiority.***

In the Me 262 the Germans had years of development behind both the turbo-jet engine and the high speed airplane. The latter was achieved through their supersonic wind tunnel research. Their experience with this airplane was rapidly leading them toward the supersonic airplane speed we hope to achieve in the future. In our own development, the advent of our jet engines has created a situation in which we do not have airplane designs capable of efficiently utilizing the high speeds they make possible.

Guided missels were not in the original research and development program of 1933. They did not receive important consideration until after the German research reorganization. However, the strong foundation of basic research and development laid for other aeronautical purposes was immediately available. The magnitude of this work was such as to provide the rapid expansion and development of some two hundred different designs and studies of guided missels. One of the best developed at war's end was a ground-to-air rocket projected by a ground director into the rear of its target. There, an infra red homing device picked up the heat from the engines and directed it into the rear of its target. It was claimed that 70 four-engine bombers were brought down with 75 of these guided missels.

Various naval devices were being used in their accelerated science to expedite aeronautical developments. In Hamburg the high speed towing basin was being used for the underwater towing of airplane components to determine their air load carrying capacity at very high air speeds. A complete airplane, the Heinkel He 162 was towed underwater in the experiment. In Goettingen, a water tunnel was being used to determine airfoil cavitation, translatable into air cavitation at high speeds.

Completely synthesized aircraft engine oils and other lubricants were in use. Precise control had been developed for each individual hydrocarbon molecule. Thus, there was achieved in war reality, a dream of our organic chemists for many years.

[By 1945, German-speaking scientists and engineers had been developing approximately 200 different types of missiles, many of which were actually fielded, ranging from the A-4 (V-2) to heat-seeking anti-aircraft missiles that were successfully demonstrated according to this report.

The Allied investigators did not even know how to spell the word "missile."

But the Allied investigators were very excited to take the German-developed missiles and other technologies.]

Albert Ducrocq. 1947. *Les Armes Secrètes Allemandes.* Paris: Berger-Levrault. pp. 96–98.

La Rheintochter était la R-1; la R-2 ne fut jamais construite industriellement, et an mai 1945, les usines allemandes auraient sorti la R-3.

Ces bombes volantes, série “R”, étaient toutes destinées à la lutte contre l’aviation alliée et elles devaient littéralement révolutionner la D. C. A. [Défense Contre Avions] [...]

Quant à la fusée auxiliaire pour le départ, elle possédait sa propre voilure cruciforme, les quatre ailes étant reliées par un système de haubans. A l’extrémité, se trouvaient cinq réacteurs. En général, cette fusée auxiliaire était abandonnée au bout de 2 kilomètres de vol et alors la R-1 prenait presque instantanément une vitesse de l’ordre de 1.500 kilomètres/heure. C’était donc bien un appareil supersonique!

La précision, déjà bonne dans la R-1, s’annonçait excellente avec les R-3, car les Allemands mettaient au point leur fameux dispositif de radar interconnecté. Il s’agissait en somme d’une carte du ciel, en l’occurrence l’écran d’un oscillographe, où apparaissait la zone balayée par l’aviation anglo-américaine; on y voyait la trajectoire des avions alliés, et la trajectoire des bombes R lancées sur eux; les servants de R-1 et de R-3 auraient ainsi pu suivre le chemin de leur engin, et, au fur et à mesure, corriger les trajectoires par radio-guidage en regardant sur le *Reichshimmel* les déplacements relatifs des avions et des bombes, cette opération, bien entendu, s’effectuant à plusieurs mètres sous terre dans un confortable abri.

C’est en se penchant sur ces réalisations que l’on peut seulement comprendre l’immense espoir de gagner la guerre qui, jusqu’à la dernière seconde, put animer certains Allemands...

The Rheintochter was the R-1; the R-2 was never built industrially, and by May 1945, German factories would have produced the R-3.

These flying bombs, the “R” series, were all intended for use against Allied aircraft, and were literally to revolutionize anti-aircraft defenses. [...].

As for the auxiliary rocket for departure, it had its own cruciform canopy, with the four wings connected by a system of stays. At the end were five jet engines. This auxiliary rocket was usually abandoned after 2 kilometers of flight, at which point the R-1 reached speeds of around 1,500 km/h almost instantaneously. A supersonic aircraft indeed!

Accuracy, already good in the R-1, was to become excellent with the R-3, as the Germans developed their famous interconnected radar system. This was basically a map of the sky, in this case the screen of an oscillograph, showing the area swept by Anglo-American aircraft; it showed the trajectory of Allied planes, and the trajectory of the R-rockets fired at them; R-1 and R-3 servicemen could thus follow the path of their vehicles, and, as they went along, correct trajectories by radio guidance, watching the relative movements of the planes and rockets on the *Reichshimmel*, this operation, of course, being carried out several meters underground in a comfortable shelter.

It is only by looking at these achievements that one can understand the immense hope of winning the war that, right up to the last second, could animate certain Germans...

[For more information from Ducrocq, see pp. 5218, 5380, 5658–5659.]

John Christopher. 2013. *The Race for Hitler's X-Planes: Britain's 1945 Mission to Capture Secret Luftwaffe Technology.* The Mill, Gloucestershire: History Press. pp. 131–132, 136–137.

Rheintochter, named after Richard Wagner's Rhine Maidens, was a multi-stage solid-fuel surface-to-air missile developed by Rheinmetall-Borsig for the German Army. [...] It was 20ft 8in (6.3m) long overall including the booster stage, and the body had a diameter of 1ft 9.25in (54cm). [...]

After eighty-two test launches, further development of the *Rheintochter* R-I, and the proposed operational version R-II, was abandoned in December 1944 because it was only attaining the same altitude as the other missile systems. A third version of the *Rheintochter*, the R-III, was to have been a far sleeker affair with a liquid-propellant rocket motor for the main stage, and it did away with the second stage in favour of solid-fuelled boosters mounted to the side of the missile. Only six test firings were made. [...]

Rheinbote ('Rhine messenger') was developed by the Rheinmetall-Borsig company in 1943. Strictly speaking this slender four-stage rocket cannot be classified as a smart bomb as it was aimed solely by the positioning of the launcher and possessed no internal or external guidance systems. Apart from the V-2 (A4) this was the only other long-range ballistic missile to enter service during the Second World War. [...]

In appearance *Rheinbote* was a slender spike 37ft (11.4m) long, with stabilising fins at the rear and three sets of smaller fins arranged at the end of each of the four stages. The rockets were fuelled by diglycol-dinitrate solid-fuel propellant and in tests achieved a blistering Mach 5.5, or 4,224mph (6,800km/h), the fastest speed of any missile at the time. *Rheinbote* was transported and launched from a modified V-2 (A4) rocket trailer which had an elevating launch gantry. The missile was aimed by orientating the trailer itself and elevating the gantry, although the accuracy of this method of aiming is highly questionable.

In tests the *Rheinbote* carried an 88lb (40kg) warhead, only 6.5 per cent of the missile's total mass, up to 48 miles (78km) into the atmosphere to a range of up to 135 miles (220km), but for shorter ranges some of the stages could be removed. Over 200 were produced and they were used in the bombardment of Antwerp from November 1944 into early 1945. After the war ended the Soviets helped themselves to the designs at Rheinmetall-Borsig's Berlin-Marienfelde headquarters, but in general the *Rheinbote* was considered to be lacking accuracy, thanks partly to the effect of the stage separations, and lacking punch as the payload was too small and the almost vertical high-speed delivery tended to bury it deep into the ground.

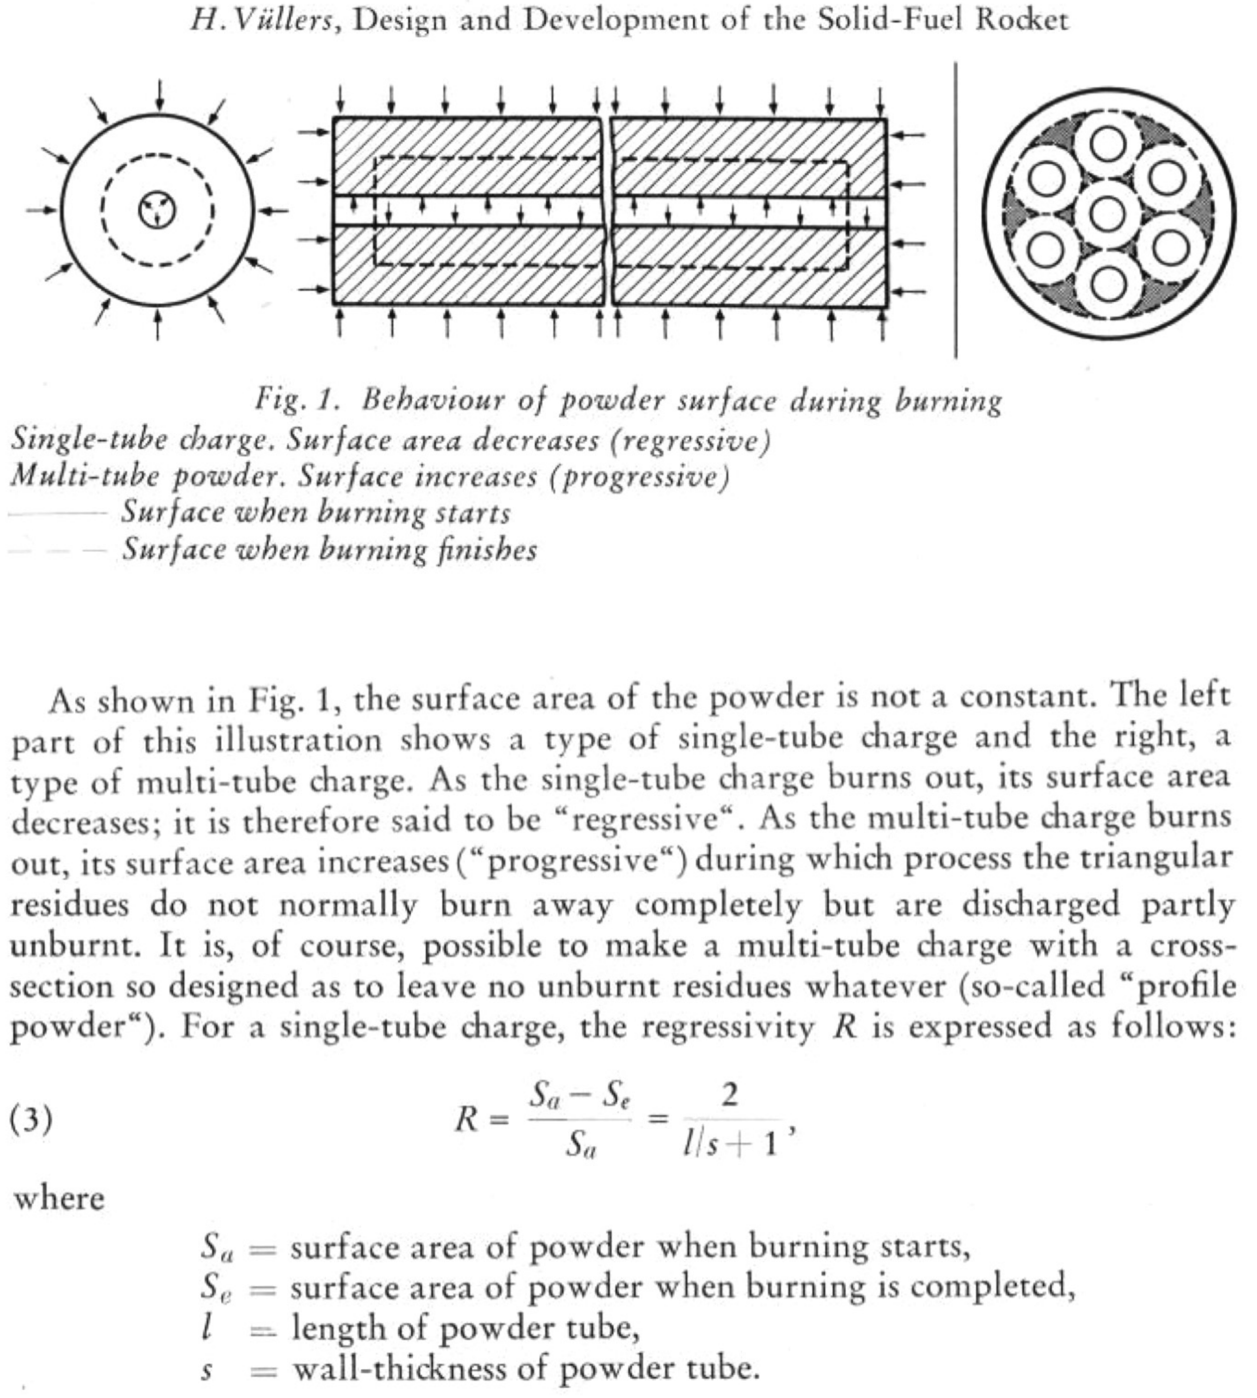
RHEINTOCHTER – ARR^CT OF SOLID PROPELLANT CHARGE

Figure E.221: Rod-and-tube grain design for constant thrust in the large Rheintochter solid propellant rocket engine [BIOS 1110, p. 10].



H. Vüllers, Design and Development of the Solid-Fuel Rocket

Fig. 1. Behaviour of powder surface during burning
Single-tube charge. Surface area decreases (regressive)
Multi-tube powder. Surface increases (progressive)
——— *Surface when burning starts*
– – – *Surface when burning finishes*

As shown in Fig. 1, the surface area of the powder is not a constant. The left part of this illustration shows a type of single-tube charge and the right, a type of multi-tube charge. As the single-tube charge burns out, its surface area decreases; it is therefore said to be "regressive". As the multi-tube charge burns out, its surface area increases ("progressive") during which process the triangular residues do not normally burn away completely but are discharged partly unburnt. It is, of course, possible to make a multi-tube charge with a cross-section so designed as to leave no unburnt residues whatever (so-called "profile powder"). For a single-tube charge, the regressivity R is expressed as follows:

$$R = \frac{S_a - S_e}{S_a} = \frac{2}{l/s + 1}, \tag{3}$$

where

S_a = surface area of powder when burning starts,
S_e = surface area of powder when burning is completed,
l = length of powder tube,
s = wall-thickness of powder tube.

Figure E.222: Hermann Vüllers's description of wartime practices for designing, calculating, and fabricating various regressive grain designs for steadily decreasing thrust (upper left) and progressive grain designs for steadily increasing thrust (upper right) [Benecke and Quick 1957, pp. 254–255].

[One of the main sources of information on solid propellant rocket development in Germany, Nils Werner Larsson, would be worthy of a complete book in his own right. He was a young engineer working on explosives in Sweden, and then in 1943 he defected to Germany and began working his way through its rocket research centers. In 1945 he provided everything he had learned about the German rocket programs to U.K. and U.S. intelligence, yet was officially condemned as a traitor by the Swedish government. Then he defected to the Soviet Union, worked his way through its rocket research centers, and came back to the West in 1960 with everything he had learned there. Currently there is not enough publicly available information to conclusively judge the true motivation behind Larsson's many moves. The most likely explanation is that he had been recruited by Western intelligence agencies to be an undercover agent first in the wartime German rocket programs, then in the postwar Soviet rocket programs. Alternatively, perhaps he just wanted to keep his life exciting by completely switching sides every few years. I would highly recommend that someone research Larsson's life more thoroughly and then make him the subject of a book and/or film.

In addition to large amounts of information about German solid propellant rockets, Larsson also provided U.K. and U.S. officials with large amounts of information about German liquid propellant rockets, including the intercontinental "V-10" (apparently another designation for the A-9/A-10). See pp. 5458–5459. Some brief reports are presented on the following pages, but where are the detailed Allied technical reports that must have been written about all of the liquid and solid rocket information that Larsson conveyed?]

Report Swedish Deserter Took Army Data to Nazis. *New York Times* 15 October 1943.

An engineer who until recently was in the service of the Swedish Army as an expert on explosives and shells has deserted to Germany with many army secrets, it is feared, according to an announcement here today. It concerns one Nils Werner Larsson, age 25, whose flight was only discovered by his failure to answer a lower court summons on charges of an expense account swindle after he had been discharged from army employment.

It now appears that Larsson fled to Germany some time this summer via Norway. He is now employed at a Berlin office of the Wehrmacht. Prior to his flight Larsson participated in a tour of Sweden's more important fortifications, among them being those at Borden and Karlsborg. His mission on this tour was to check grenade throwers, on which he was considered to be an expert. Prior to this he had also been engaged on many secret and highly confidential missions in connection with Swedish defense.

Nils Werner Larsson. 8 June 1945 interrogation at Augsburg [AFHRA C5094, frames 0874–0890].

[This is a lengthy written account by Larsson that described his personal history from the 1930s to 1945. While it did not provide many technical details of German projects, it did include his claim that in 1943, he was recruited and trained by U.S. and U.K. intelligence to work undercover on German military research programs.]

Engineer Arrested as Swedish Traitor. *Toronto Daily Star* 1 November 1945 p. 20. [http://news.google.com/newspapers?id=29QXAAAAIBAJ&sjid=pSMDAAAAIBAJ&pg=7981,5176166&dq=nils+werner+larsson]

Nils Werner Larsson, a Swedish Engineer, has been arrested by Swedish police at Charlottenburg on his way home from Norway.

It is reported that four years ago he wanted to go to Germany to do intelligence work for Britain. The Germans didn't trust him and he had to find some way to show them that he was apparently a friend of Germany, so he stole drawings of a new Swedish gun.

When the war ended Larsson went over to the British lines.

Ein Mann namens Larsson [A Man Named Larsson]. *Die Zeit* 11 March 1960 p. 4. [https://www.zeit.de/1960/11/Ein-Mann-namens-Larsson]

[...] Jenes andere Beispiel aber, von dem es hier zu erzählen gilt, ist die Geschichte des schwedischen Ingenieurs Nils Werner Larsson. Der Schwede hat mehrere Jahre als westlicher Agent hinter dem Eisernen Vorhang gelebt, ist ins Zentrum der östlichen Raketenforschung vorgedrungen, hat fünf Monate vor dem ersten Sputnik den Start einer roten Großrakete miterlebt und behauptet, er kenne das Geheimnis der atomgetriebenen sowjetischen Super-Rakete. Mit diesem Wissen meldete er sich jüngst wieder im Westen, bei den Dienststellen der US-Army. [...]

[...] But the other example we have to talk about here is the story of the Swedish engineer Nils Werner Larsson. The Swede lived behind the Iron Curtain as a Western agent for several years, penetrated the centre of Eastern missile research, witnessed the launch of a large communist rocket five months before the first Sputnik and claims to know the secret of the nuclear-powered Soviet super-rocket. With this knowledge he recently contacted the US Army again in the West. [...]

LARSSON, Nils, a Swedish engineer who has worked for two years in Germany on rocket research. He appears to have a well-rounded picture of German rocket production and plans, and although he admits that he is only a "small man in this field", he knows the more important men and where they can be found. [...]

Seventh Army Interrogation Center. 3 June 1945. Notes on German Weapons Developments. SAIC/38. [https://www.scribd.com/document/431240796/File-Datastream http://hydrastg.library.cornell.edu/fedora/objects/nur:01298/datastreams/pdf/content]

I. PREAMBLE

The following information was obtained from Dr Edgar RUPPELT, Dr Alfred NORDT, Dr Ernst KNUST, and Nils LARSSON, all of the PIBRANS, Czechoslovakia, SKODA Works Rocket Experimental Station. While all of them gave a certain amount of information, LARSSON, the head of the group, can be considered the main source.

LARSSON, Nils, is a 27-year-old Swedish engineer whose special field was the development of new weapons, especially in the rocket category. In summer 40 a proposed A/T weapon of his design was accepted by the Swedish military authorities. He attended a military technical school for some time and in winter 42/43 met the Norwegian Military attaché, Lt Col SMITH-KIELLAND, and through him, the American and British Military Attachés in STOCKHOLM. He attempted to leave Sweden to work for the United Nations, he claims, and when this proved impossible due to difficulties in transportation, he got in touch with an American intelligence official, a "Col ANDREWS", and a representative of the British Secret Service, a "Mr GREEN", who instructed him to go to Germany and keep in close touch with the latest developments in rockets and other weapons. Source claims to have obtained definite instructions as to his proposed mission in Germany.

Through a representative of the German Military Attaché, a 1st Lt "MÜLLER-LIEBENAU", source obtained permission to enter Germany as specialist in rocket development.

Source worked at first, starting on 1 Jul 43, for the firm MAGET in BERLIN/TEGEL. In order to avoid troubles with the German Police, his case was cleared by the German authorities through the at the time unimportant SS HPTSTUF (Capt) SKORZENY. Due to SKORZENY's subsequent rise in power and importance, it was possible for source to gain access to the top German agencies involved in the development of new weapons.

After short periods of work in various smaller agencies involved in rocket experiments, source was sent to the VERSUCHS-ANSTALT (Research Center) GROSSENDORF, on the HELA Peninsula, about May 44. Here source had occasion to acquaint himself with the latest developments in the rocket field, as well as to get to know the names of the leading scientists involved in the experiments and research work. From here, source claims, he sent reports through a contact-man in BERLIN as well as through his wife in STOCKHOLM. Furthermore, source made contact with the leading scientists of the Torpedo Research Center GOTENHAFEN (GDYNIA), which was a sub-post of the MARINE REICHSVERSUCHSANSTALT (REICH Naval Experimental Station), KIEL.

In winter 44/45 the GROSSENDORF Center was evacuated to PIBRANS, Czechoslovakia, where, together with the Research Post of the PIBRANS SKODA Plant, it formed a new elaborate Research Center under Eng Rolf ENGEL, former head of the GROSSENDORF Center. In Apr 45, when Germany's collapse was near, this Center was dissolved and the personnel were given permission to leave Czechoslovakia. Source left for Southern Germany, securing on his way important scientific data as well as some secret Police documents applying to the plant.

Source appears to have had occasion to form an overall picture not only of the latest developments in the rocket field, but in the general line of research on other new secret weapons as well. Due to his travels and his access to data in the top German research centers, he knows a remarkable number of names connected with latest German scientific developments. He wants, with the help of American and British influence, [to] re-instate his "good name" in Sweden where, it seems, he is regarded as a traitor because of his departure for Germany. Whatever his reasons, he is cooperative and helpful. He has an excellent memory, and his information is considered reliable.

Rating: B-2 Date of Information: Beg. May 45 Interrogator: M.N.

NOTE: The following report should be regarded as basis for further specialized interrogation. It is believed that sources would be able to furnish detailed technical data on many of the instruments described as well as on the experiments carried out. It should be noted that source LARSSON was Specialist in Charge (SACHBEARBEITER) of some of the developments.

[...]

II. GERMAN AGENCIES SUPERVISING RESEARCH AND DEVELOPMENT OF NEW WEAPONS [...]

ii) TORPEDO VERSUCHSANSTALT (Torpedo Research Center), GOTENHAFEN. KAP Z SEE (Navy Captain) PRALL was the head of the Center. In charge of the development of special torpedos was Dr SCHMIDT, and in charge of development of the "ROCHEN" ("Roe"—see III, A, 5, a, below) was Dipl Ing WONDRAK. [...]

Under the FORSCHUNGSFUEHRUNG source recalls the following departments:

i) RHEINTOCHTERENTWICKLUNG ("RHINE Daughter" Development - see III, A, 5, b, below). The man in charge of these experiments (REFERENT) was Prof Dr ORTHMANN.

ii) R-ENTWICKLUNG (Rocket Development), headed by Maj HARRAS. Specialists in Charge (SACHBEARBEITER) were HPTM (Capt) TILLING and FL STABSING (GAF Maj) HESSE.

iii) PULVERENTWICKLUNG (Powder Development); REFERENT in FoFü for this dept was Dr BUNDE. [...]

f) RUESTUNGSKOMMISSIONEN MIT FUEHRERVOLLMACHT (Armament Commissions with FUEHRER Authority) [...]

iii) PULVERKOMMISSION (Powder Commission), headed by the General Director of DYNAMIT AG Dr Paul MUELLER. Specialist in interior ballistics and powders in this dept was REGIERUNGSBAURAT Dr POEPL, who also was in Wa Prüf 1. HPTM (Capt) Dr HIMMELHEBER, specialist of small assemblies for V-1, was head of the section for research in wood.

iv) SONDERKOMMISSION FUER R-ENTWICKLUNG BEIM RfRuK (Special Commission for Rocket Development in the SPEER Ministry) was headed by FL STABSING (GAF Maj) ZEYSS.

v) SONDERAUSSCHUSS FUER PULVER BEIM RfRuk (Special Section for Powder in SPEER Ministry) was headed by Director Dr WUNDER. [...]

III. GERMAN RESEARCH ON NEW WEAPONS

[...]

1. Projectors [...]

a) M 8 Projector

This projector, research on which was supervised by the SS WAFFENAMT (Ordnance Office) through SS HPTSTUF (Capt) HANNEBERG, was developed in the WAFFENWERKE BRUENN AG and in the GROSSENDORF, Pomerania, Research Center under Ing Rolf ENGEL. The specialists in charge of the research and experiments were Dr KALSCHEUER, Prof Dr BOEDENWADT, and Ing PROKOP. The projector has 48 barrels on a SP chassis. The rockets are 8 cm in diameter, have flight stabilizers and percussion fuzes. The maximum range of the rockets is 7 km. [...]

2. Rocket AA Weapons [...]

a) ORKAN FLA

This weapon, ordered by the OKL, ARBEITSSTAB (Staff) DORNBERGER and supervised by FL STABSING (GAF Maj) ZEYSS, was being developed in the Research Center of the WAFFEN-UNION in PIBRANS, Czechoslovakia. OBLT (1st Lt) FISCHER and Dr TEICHMANN were the specialists in charge of the experiments and research. The projector, consisting of 24 rails on a rotating chassis, was to be used against low-flying planes. The rockets have a cal of 55 mm, percussion fuzes, and flight stabilizers. They attain a distance of 5 km in 3 sec. The powder charge is placed in a single tube 48 x 15 x 1,100 mm and weighs 1.7 kg; the weight of the explosive charge carried by the rocket is 500 g. The experiments on the weapon were concluded, and it was planned to manufacture the first 50,000 rockets for combat employment. [...]

5. Controlled Rocket Weapons

a) ROCHEN ("Roe")

This is a rocket projectile which is controlled by means of impulses transmitted through a wire unwinding during its flight (see F, 2, below). The OKM (Navy High Command) was the agency interested in the development of this weapon, and Director SCHMIDT of the TVA (Torpedo Research Center), GOTESHAFEN was supervising the experiments. The research and experiments were carried out in the TVA GOTESHAFEN and in the GROSSENDORF Research Center under the supervision of KAP Z SEE (Navy Captain) VON PRALL. SACHBEARBEITER (specialists in charge) were Ing WONDRAK and Dr KALSCHEUER. The ROCHEN was to be used against naval and land targets. The projectile is 2 m long and approx 1 m wide. It has both a rocket starting mechanism (the DOV 21 is used for this purpose) and a rocket propelling device. The weight of the projectile before it is fired is 320 kg, of which 100 kg are the "Useful weight". Its flight can be controlled to a distance of 4–7 km, through a polarisation relay. The weight of the powder is 16[0] kg, the combustion time 3 tons-sec. The device was ready for experiments when hostilities ceased.

b) RHEINTOCHTER ("RHINE Daughter") (Source: Dr NORDT)

This is a controlled heavy AA missile, developed by RHEINMETAL-BORSIG, BERLIN/MARIENFELDE, under the management of Dr KLEIN, for the OKL. Supervisor of the project on the part of the OKL was Prof Dr ORTHMANN, and specialist in charge during the experiments and research work was OBERING MUELLER. The shell, containing an explosive charge of approx 100 kg, was to be used against bomber formations. It is controlled by means of an infra-red device, and has an acoustically controlled fuel ignition cut-out. The device consists of two parts, a starting device and a propelling device, each with a thrust of 25–30 tons and a fuel combustion time of approx 2 sec. After the ignition of the propelling device, the empty starting device is automatically dropped. It was planned to substitute the propelling device by a long-burning powder device, with a fuel combustion time of 30 sec, or by using a liquid propellant (SCHMETTERLING and WASSERFALL). Sources state that the steering problems of the "RHINE Daughter" had not been solved, as of beg May 45. Research was carried on up to the last minute.

7. Long Range Rocket Missiles

The V-series weapons are the representatives of this class. Also, future developments for communication purposes can be expected in rockets of this category.

a) V-l.

b) A-4, which was the prototype of V-2.

c) V-2.

d) TL (TURBOLADER)—for jet-propelled planes.

e) V-101.

This weapon, in the planning stages only, was being developed in the PIBRANS Experimental Center by Dr BOEDENWADT, Dr TEICHMANN, Dr KALSCHEUER, and Ing THOMAS. It is a giant rocket of a total weight of 140 tons, of which 100 tons were to be taken up by the fuel. It was to have a length of 30 m and a diameter of 2.8 m. It was to attain a velocity of 2,000 km per hour at an altitude of 200 km. Its maximum range was calculated to be 1,800 km. It was to be fired by a catapult mechanism, also rocket-operated. Source LARSSON claims that he would be able to prepare a complete report, with drawings, of this weapon. [...]

3. Heterogen Powders [...]

b) PER Powder

This powder was developed in the PIBRANS Experimental Station, under Dr TEICHMANN. Its developments were supervised by FL STABSING (GAF Maj) ZEYSS, of the OKL. The powder was synthesized from a plastic material and an inorganic oxygen carrier. Depending on this plastic material, the powder could be molded or poured into shape. The burning proceeds uniformly at atmospheric pressure and up. The linear burning velocity at one atm is 1 mm/sec. The burning velocity increases proportionately to the increase of pressure.

F. MEASURING AND AUXILIARY DEVICES

1. Radar Devices

Sources mention the DARMSTADT Device and Y-Device as the latest developments in this field.

2. Wire Control Device

This is the spinner used in the ROCHEN and wire controlled torpedo. It was developed in the TVA (Torpedo Experimental Station) GOTENHAFEN (GDYNIA) the head of which was KAP Z SEE (Navy Captain) VON PRALL, by Dir SCHMIDT and Dipl Ing WONDRAK, and several series of the device were already manufactured. The missile is controlled through polarization relays over a wire which unrolls during its traveling. The range of the device (and thus of the missile) is said to be from 7 to 12 km.

3. Remote-Control Devices

Generally, the devices send out high frequency signals, modulated light signals, infra-red, or acoustic signals. Sources know of a modulated-light device which was being developed at the PIBRANS Experimental Station by Dr SIMON and Dr TRENKA, under the supervision of OBLT (1st Lt) FISCHER, of OKL/GL FLAK. The device is said to have passed the experimental stage, as of beg May 45.

[This solid propellant mixture was probably dubbed "per powder" because its dominant ingredient was ammonium perchlorate. Was the Zeyss mentioned here the same as Wilhelm Zeyss (p. 1910), who played a role in other solid propellant rocket programs?]

[p. 190:]

V-101 LONG RANGE ROCKET

A. General

1. Introduction.

(a) The V-101 is a long range rocket missile which was in the planning stages at the Pibrans Rocket Experimental Station, a subsidiary of the SKODA Munitions Work at Pibrans, Czechoslovakia. The only information presently available is from a brief interrogation of Dr. Edgar Ruppelt, Dr. Alfred Nordt, Dr. Ernst Knust and Nils Larsson, in the 7th Army Interrogation Center. (Report Ref. No. SAIC/38 of June 1945).

(b) No drawings or illustrations are available.

(c) As in the case of the Rochen, reference to the V-101 has been made simply as an illustration of the extent of the German effort being utilized in the development of long range rockets and missiles.

B. Details

2. Description.

(a) It is believed that the projected purpose of the weapon was for use in long range area bombing. The type of explosive, fuel, and exact utilization had not been fully determined. The missile was to operate in the stratosphere.

(b) The rocket was to be about 30 meter long; the diameter was estimated to be 2.8 meters. The total weight was to be approximately 140 tons, with the fuel weight of approximately 100 tons.

(c) The speed of the rocket was estimated to be in the vicinity of 2000 km/hr when operating at an altitude of 200 kilometers. The proposed range was to be 1800 kilometers.

(d) The rocket was to be launched from a catapult mechanism.

[In the table of rockets on p. 46 of this report, the numbers from p. 190 of the report are repeated, but the thrust is indicated as 100 tons, and all other details are listed as “not known.” In order to lift off, the rocket’s thrust must be larger than the rocket’s weight, so the actual thrust must have been greater than 140 tons.

This report stated that its only information on the V-101 came from the SAIC/38 interrogation report, which did not indicate the thrust of the rocket. The most likely explanation is that whoever typed the table in this NavTechMisEu 237-45 report misread the reported fuel weight of 100 tons as being a thrust of 100 tons.

A less likely explanation is that whoever typed this table was thinking of a thrust of 200 tons but mistyped it as 100 tons. 200 tons of thrust would give a very plausible thrust-to-weight ratio for a rocket weighing 140 tons when launched.

Note that the name given as “Dr BOEDENWADT” in SAIC/38 has been mangled to “BUEDENWADT” in this NavTechMisEu 237-45 report.]

HEC 5787. Headquarters, U.S. Forces, European Theater, Alsos Mission. 15 September 1945. Subject: Survey of Facilities in Germany for Development of Guided Missiles. [NARA RG 319, Entry NM3-82, Box 1582]

Part V

Development and Fabrication of Complete Missiles

[...] K. Skoda "V-101"

The large munitions work Skoda in Pilsen, Czechoslovakia, operated a rocket experimental station at Pribrans, Czechoslovakia. Here work was being done towards the development of a stratosphere rocket 100' long and weighing 140 tons.

L. "Rochen" ("Roe")

This was a rocket projectile for wire control under development by the Torpedo Research Station Gotenhaven. Tests were conducted there and at a research station Grossendorf. This project was under the cognizance of the Navy High Command.

[The Alsos Mission traveled around Europe independently investigating a wide range of scientific innovations and collecting vast numbers of German documents. Was this statement in HEC 5787 based on their own investigations, or was it simply rephrased from the earlier U.S. and U.K. reports?

As an example of at least one relevant German document collected by Alsos, please see the following pages. Was Alsos's statement that "work was being done towards the development of a stratosphere rocket 100' long and weighing 140 tons" based on other documents that they collected? If so, where are those documents now?

From this statement in HEC 5787, the V-101 sounds like more than a paper design study. The Alsos Mission reported the V-101 under the heading of "Development and Fabrication of Complete Missiles," alongside fully built (if not perfected) projects such as the Rochen wire-guided missile and Natter vertical take-off rocket plane, and with the wording that there was "work" toward its "development." It would have been very difficult to fully build such a large rocket, but what development work was actually done?]

Figure E.225: Excerpts from a 49-page book from Rolf Engel and Wilhelm Zeyss listing definitions of mathematical variables used for calculating the performance of solid propellant rockets, collected by the U.S. Alsos Mission. [NARA RG 319, Entry NM3-82A, Box 14, Folder OB-3]

Fritz Hahn. 1998. *Waffen und Geheimwaffen des deutschen Heeres 1933-1945.* 3rd ed. Bonn: Bernard & Graefe. Vol. 2, pp. 180, 182.

V 101

Unter dieser Bezeichnung hatten 1944 Dr. Büdewald und Dr. Teichmann im *Zweigwerk Pibrans* der Firma *Skoda* mit der Entwicklung einer großen Feststoff-Rakete begonnen.

Bei 30,000 mm Länge und 2800 mm Durchmesser sollte diese dreistufige Rakete 140 t wiegen. Das Pulvertriebwerk der ersten Stufe war für einen Schub von 100 t ausgelegt, die rechnerische Flugbahn zeigte bei einer Reichweite von 1800 km eine Gipfelhöhe von 200 km. Der Entwurf war nur in groben Zügen festgelegt, über Einzelheiten existieren keine Unterlagen mehr. Dieses Projekt wäre, wie andere auch am Treibmittel, dem immer knapper werdenden Pulver gescheitert.

V 101

Under this designation Dr. Büdewald and Dr. Teichmann started the development of a large solid propellant rocket in the Pibrans branch of the Skoda company in 1944.

At 30 m in length and 2.8 m in diameter, this three-stage rocket was supposed to weigh 140 tons. The powder [solid propellant] engine of the first stage was designed for a thrust of 100 tons; the calculated trajectory showed a peak altitude of 200 km with a range of 1800 km. The design was only laid out in general outline; documents about details no longer exist. This project, like others on the propellant, failed because of the increasingly scarce powder.

[Almost all of Fritz Hahn's information appears to have come from the NavTechMisEu 237-45 report, including the erroneous thrust of 100 tons.

Dr. "Bödenwadt" (from SAIC/38) or "Büdenwadt" (from NavTechMisEu 237-45) has been further altered to "Büdewald." The scientist's actual name was Uwe Bödewadt (German, 1911–2003).

The only major new technical detail added by Hahn is that the rocket had three stages. That does not appear to be stated anywhere in the available U.S. or U.K. reports. Was that simply a guess by Hahn, or did sources with knowledge of the project give that additional information to Hahn? For the projected performance characteristics of the V-101, it seems probable that it would have had 2–4 stages, so three stages is highly plausible.]

BIOS 571. ***German Rocket Propellants (Interrogation of Mr. N. W. Larsson).***

I. Introduction

Mr. N. W. Larsson is an engineer with great faculties of memorising technical data. He is a Swedish subject, talks German fluently, and claims that he went to Germany as an allied spy, working for the British Secret Service.

Mr. Larsson has been employed in German Armament Research from May 1943 to V.E. day. He first spent some months at the Rheinmetall-Borsig factories where he worked on the "Gehrlich" recoilless gun.

He was then transferred to Peenemünde, where he assisted in the development of various rocket weapons.

In December 1944 he went with the Peenemünde staff to a research station of the Skoda Works at Pibrans, Czechoslovakia, when he carried on his work until the cessation of hostilities.

During the interrogation Mr. Larsson gave some information upon the German 'alternative' rocket propellants Per-pulver and Giessling-pulver, as well as some indication upon the technique employed in making "cigarette-burning" charges.

II. Per-pulver

Mr. Larsson worked with the applications of this propellant to various rocket weapons, at the Skoda Works Rocket Research Station at Pibrans, Czechoslovakia, for about 6 months. Here he met the inventor of Per-pulver, Dr. Teichmann, and his two collaborators, Dr. Knust and Dr. Nord.

Per-pulver is also called Nider-druck-pulver, Super-pulver and Dauerbrand.

Composition:

Ammonium perchlorate	25–40%
Buna S3	25%
Vinapas	50–35%
Stabiliser	3–5%

Later interrogations of Dr. Teichmann, however, show that these figures are not exact. The composition contains about 80% of ammonium perchlorate.

Ingredients:

Buna S3. It appears that this synthetic rubber corresponds to Buna SG. Delivered in sheets, vulcanised, 2–3 mm. thick, the sheets being in rolls of about 100 Kg. weight.

The sheets were disintegrated in special machines, down to dimensions of the order of 3–5 mm. (The synthetic rubber industry was later asked to deliver the rubber in a more favourable state, such as an intermediate product consisting of small grains).

Vinapas. Produced by Wacker Chemie, Burghausen near Salzburg. This is a synthetic plastic, which also appears under other commercial names. It is used as a binder, conferring to the propellant a consistency somewhat like a plastic. The yellow colour of the propellant is due to the Vinapas. It is used as small flakes or a fine powder.

Ammonium perchlorate. It is added as fine crystals (particle size roughly as ordinary table salt). Also other perchlorates have been used, such as sodium perchlorate.

Preparation of the propellant.

The ingredients are mixed at room temperature (plus 15^{o}C) in a usual rotating incorporator. The mixture is then rolled on a roller-mill of the usual type employed for Digl. pulver.

The initial temperature is 60^{o}C, which is increased during milling to 90–95^{o}C. The milling time is dependent on the consistency of the dough, which in turn varies with the proportions of the constituents. The time appears to be 25–30 mins. for a batch of 25 Kg.

Mr. Larsson's notes do not make quite clear at which state of the process the perchlorate is introduced. On one occasion he said that it was added on the rolls, when a sheet was formed, and this appears to be most likely, as this procedure would be the safest.

The resulting dough is extruded or molded. The extrusion press is worked very much in the same way as for Digl. pulver. The extrusion pressure is, of course, dependent of the temperature.

The molding is, however, the most important method of preparing propellant charges, as it makes possible the production of charges of almost any size and shape. The propellant is molded at 110–120^{o}C, in jacketed moulds preferably warmed to a somewhat lower temperature. This temperature is maintained for 5–10 min. to allow air bubbles to mount and assemble in the upper part of the mould. The jacket is then cooled rapidly with cold water. After solidification of the propellant the mould is taken to pieces. 4–6 inches is cut off the top of the charge, to take away any air bubbles that may be included owing to the more rapid cooling of the surface of the charge during molding. The surface is then polished.

Ballistic properties.

The rate of burning exponent is "somewhat lower than 1". The propellant burns regularly under low pressure. It appears that the highest specific impulse was obtained when the propellant is burning at 25 atm. (350 p.s.i.) The flame temperature also gives a maximum at this pressure (1600^o–1800^{o}C.).

The rate of burning at 25 atm. is claimed to be 25 mm/sec. Striction ratio K=50–80.

There is danger of detonation when the pressure rises to 1100 atm. at which pressure the rate of burning is 1000 mm/sec. The pressure limit for which detonation occurs is increased by introducing more Vinapas in the propellant.

Physical properties.

Consistency somewhat like a plastic.
d- 1.85 to 1.90
Colour yellow to brown.
Smooth, hard surface.
Can be worked with cutting tools.

Applications.

Per-pulver was used in the A.T.O. unit of "Rochen", where it was burning at a pressure of 25 atm. with a rate of burning of 25 mm./sec.

"Rochen" is a heavy rocket missile, guided by wires. It was intended for use from light vehicles and MTBs against shipping and ground targets.
Weight about 300 Kg., 150 Kg. of explosives.
Guided by the "Spinner" system.

[This solid propellant mixture was probably dubbed Per-pulver or "per powder" because its dominant ingredient was ammonium perchlorate. It is mentioned in several of the documents in this section, and this appears to have been the origin and first use of truly modern solid propellant rocket propellant.

Where are the "later interrogations of Dr. Teichmann" that gave complete details about the solid rocket propellant, as mentioned in this report? An early interrogation of Teichmann appeared in the following report, BIOS 31, but in that early interrogation Teichmann was unwilling to reveal many of the details of his work on solid rocket propellant. Somewhere there must be much more detailed written reports on later interrogations of Teichmann, or even wartime or postwar reports written by Teichmann or others from his research group. Can those reports be located in archives?]

Hermann Teichmann. 7 June 1945. Survey of research work of Dr. Teichmann group [AFHRA C5094, frames 0770–0772]

[After the war, Hermann Teichmann and several other members of his solid propellant rocket group were interned at Camp Föhrenwald-Wolfratshausen in Bavaria by U.S. forces. They wrote this three-page letter to the American military occupying government in Munich offering their services to work for the United States. Without going into technical details, they explained that they had made important new inventions and discoveries with regard to solid rocket propellants.

While they were never hired by the United States or United Kingdom, they were apparently interrogated extensively by U.S. and U.K. scientific investigators. After they were released, they went to work in France.]

Z. Hd. Herrn Hauptstf. Ing. Engel und Herrn Dr. Teichmann.

Betr.: Versuche mit der neuen Masse für R-Geschosse.

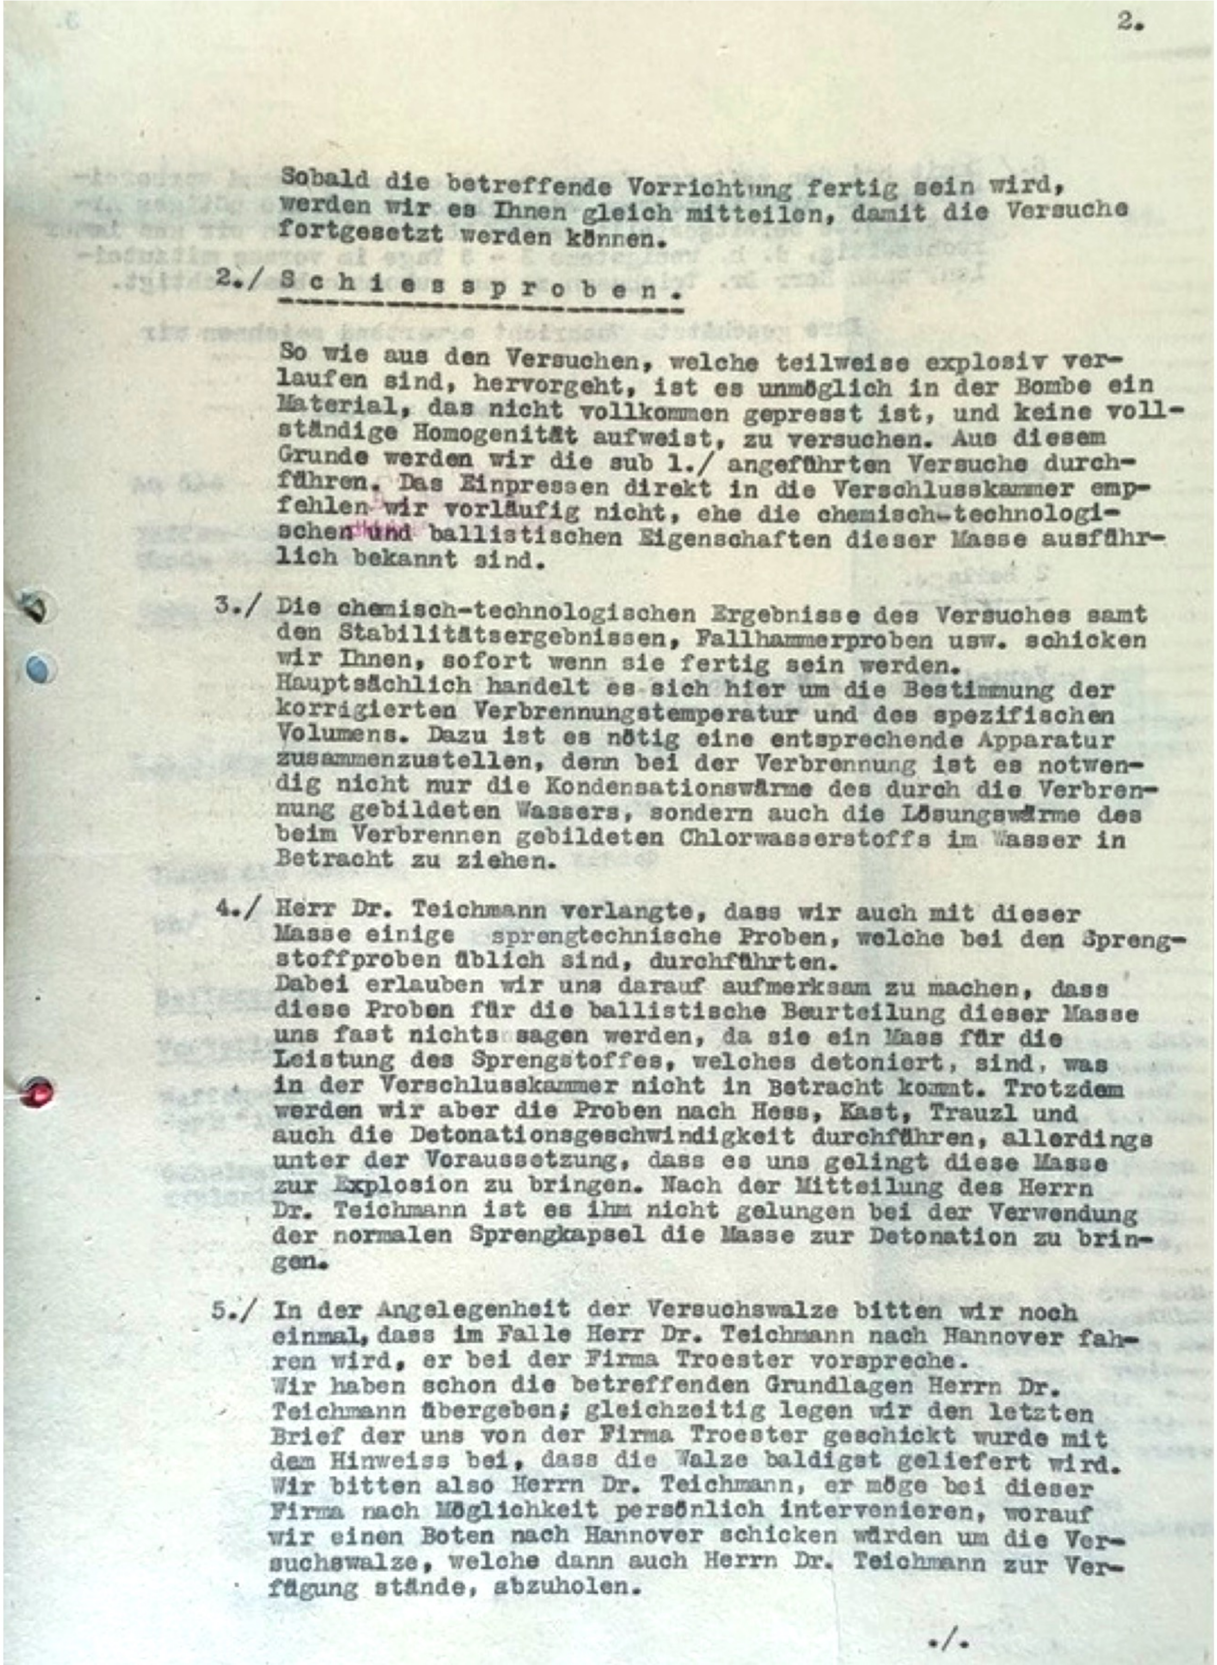
Zur ganzen Angelegenheit und zu den in Gemeinschaft mit Herrn Dr. Teichmann durchgeführten Versuchen, erlauben wir uns folgendes mitzuteilen:

1./ Pressen:

Wie aus den Versuchen hervorgeht, ist es unmöglich die Presslinge auf statische Weise anzufertigen und daher nötig das Röhren- oder Stangen - Pressen entweder auf der Schneckenpresse oder so wie bei rauchlosem Pulver durchzuführen.
Wie wir schon Herrn Dr. Teichmann mitgeteilt haben, steht die Schneckenpresse bei uns nicht zur Verfügung, die Versuche auf der grossen Betriebspresse können aber aus Sicherheitsgründen nicht eher durchgeführt werden als uns sämtliche Eigenschaften dieser Masse genau bekannt sein werden. Um aber die Versuche fortsetzen zu können, meinen wir, dass es am besten wäre, die Normalladungen für die 8 cm R-Granate, d. h. die Röhrengrösse 23/6 cm, auszupressen.
Da wir die Arbeiten aus den obenangeführten Gründen auf der Betriebspresse nicht durchführen können, werden wir eine Adaptation auf der kleinen Versuchspresse durchführen und so die Masse auf die verlangten Dimensionen auszupressen versuchen.
Herr Dr. Teichmann hinterlies uns eine Zeichnung, welche wir in der Beilage schicken, die uns aber nicht klar ist. Wir bitten also um eine genauere Zeichnung, respektive um eine genauere Stylisierung der Erfordernisse.
Im Falle, dass es sich um eine Matrize für die Dimensionen 23/6 handelt, erlauben wir uns mitzuteilen, dass die Konstruktion auf Grund der bisherigen Erfahrungen unserer technischen Gruppe ausgearbeitet sein wird.

./.

Figure E.226: 20 November 1944 letter demonstrating the involvement of Hermann Teichmann and Rolf Engel in tests of a solid rocket propellant that produced hydrochloric acid in the exhaust (a key characteristic of Per-pulver, due its ammonium perchlorate—see p. 5691).



2.

Sobald die betreffende Vorrichtung fertig sein wird, werden wir es Ihnen gleich mitteilen, damit die Versuche fortgesetzt werden können.

2./ Schiessproben.

So wie aus den Versuchen, welche teilweise explosiv verlaufen sind, hervorgeht, ist es unmöglich in der Bombe ein Material, das nicht vollkommen gepresst ist, und keine vollständige Homogenität aufweist, zu versuchen. Aus diesem Grunde werden wir die sub 1./ angeführten Versuche durchführen. Das Einpressen direkt in die Verschlusskammer empfehlen wir vorläufig nicht, ehe die chemisch-technologischen und ballistischen Eigenschaften dieser Masse ausführlich bekannt sind.

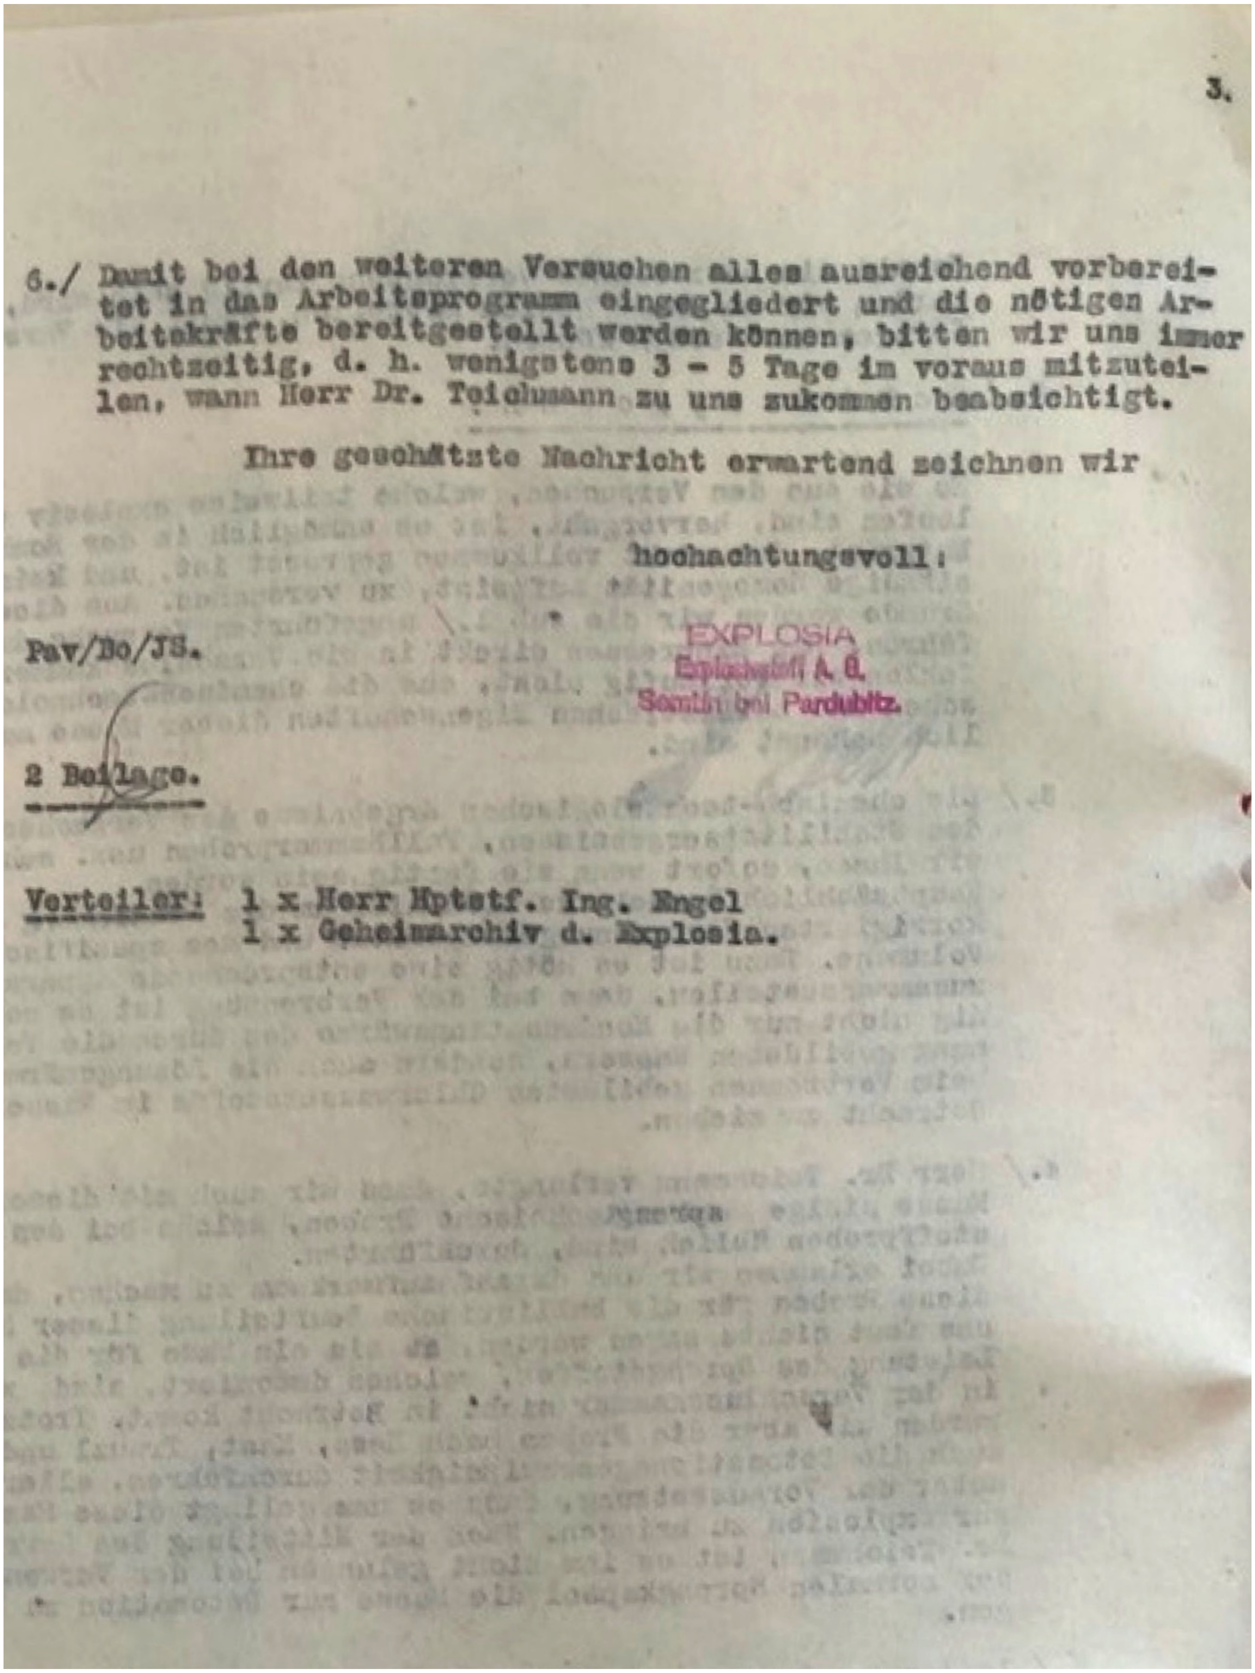
3./ Die chemisch-technologischen Ergebnisse des Versuches samt den Stabilitätsergebnissen, Fallhammerproben usw. schicken wir Ihnen, sofort wenn sie fertig sein werden.
Hauptsächlich handelt es sich hier um die Bestimmung der korrigierten Verbrennungstemperatur und des spezifischen Volumens. Dazu ist es nötig eine entsprechende Apparatur zusammenzustellen, denn bei der Verbrennung ist es notwendig nicht nur die Kondensationswärme des durch die Verbrennung gebildeten Wassers, sondern auch die Lösungswärme des beim Verbrennen gebildeten Chlorwasserstoffs im Wasser in Betracht zu ziehen.

4./ Herr Dr. Teichmann verlangte, dass wir auch mit dieser Masse einige sprengtechnische Proben, welche bei den Sprengstoffproben üblich sind, durchführten.
Dabei erlauben wir uns darauf aufmerksam zu machen, dass diese Proben für die ballistische Beurteilung dieser Masse uns fast nichts sagen werden, da sie ein Mass für die Leistung des Sprengstoffes, welches detoniert, sind, was in der Verschlusskammer nicht in Betracht kommt. Trotzdem werden wir aber die Proben nach Hess, Kast, Trauzl und auch die Detonationsgeschwindigkeit durchführen, allerdings unter der Voraussetzung, dass es uns gelingt diese Masse zur Explosion zu bringen. Nach der Mitteilung des Herrn Dr. Teichmann ist es ihm nicht gelungen bei der Verwendung der normalen Sprengkapsel die Masse zur Detonation zu bringen.

5./ In der Angelegenheit der Versuchswalze bitten wir noch einmal, dass im Falle Herr Dr. Teichmann nach Hannover fahren wird, er bei der Firma Troester vorspreche.
Wir haben schon die betreffenden Grundlagen Herrn Dr. Teichmann übergeben; gleichzeitig legen wir den letzten Brief der uns von der Firma Troester geschickt wurde mit dem Hinweiss bei, dass die Walze baldigst geliefert wird. Wir bitten also Herrn Dr. Teichmann, er möge bei dieser Firma nach Möglichkeit persönlich intervenieren, worauf wir einen Boten nach Hannover schicken würden um die Versuchswalze, welche dann auch Herrn Dr. Teichmann zur Verfügung stände, abzuholen.

./.

Figure E.227: 20 November 1944 letter demonstrating the involvement of Hermann Teichmann and Rolf Engel in tests of a solid rocket propellant that produced hydrochloric acid in the exhaust (a key characteristic of Per-pulver, due its ammonium perchlorate—see p. 5691).



3.

6./ Damit bei den weiteren Versuchen alles ausreichend vorbereitet in das Arbeitsprogramm eingegliedert und die nötigen Arbeitskräfte bereitgestellt werden können, bitten wir uns immer rechtzeitig, d. h. wenigstens 3 - 5 Tage im voraus mitzuteilen, wann Herr Dr. Teichmann zu uns zukommen beabsichtigt.

Ihre geschätzte Nachricht erwartend zeichnen wir

hochachtungsvoll:

Figure E.228: 20 November 1944 letter demonstrating the involvement of Hermann Teichmann and Rolf Engel in tests of a solid rocket propellant that produced hydrochloric acid in the exhaust (a key characteristic of Per-pulver, due its ammonium perchlorate—see p. 5691).

BIOS 31. ***Rocket Developments in South Germany and Austria.***

[pp. 8–11:]

Target	Dr. Hermann Teichmann.	(E)
Location	Lager Föhrenwald (D.P. camp) Wolfratshausen. M.48 WY. 778 (U.S. zone)	
Nature of Target	Research chemist.	
Date visited	2.8.45.	

Dr. Teichmann graduated at Hanover in 1937 and then worked as an assistant to Prof. Jost at Hanover and at Leipzig.

He worked for various organisations including the German Air Ministry in Berlin and Strassbourg, leaving the latter city in August 1944 to continue work in the explosives (H.E.) factory at Wolfratshausen. There he was in charge of a group developing solid propellants for rockets. He is still in touch with other members of his group and is desirous of continuing his work.

He was to a large extent co-operative, but frankly admitted that he did not intend to reveal all the results of his work to everybody who questioned him, without some assurances regarding his future.

From 1937 until quite recently he was engaged on an academic study of gaseous combustion. [...]

He stressed the importance of the gaseous reactions as the factor controlling the rate of burning of solid propellants, and claimed to have based his design of a propellant on the results of his study of gaseous combustion.

According to his theories, any solid propellant, the burning of which involves a "liquid" layer between the solid unburnt propellant and the gaseous phase, will not burn reliably at low pressures, because the rate of the slowest reaction in the gaseous phase is slower than the rate of thermal decomposition of the solid. The result is "chuffing" and incomplete combustion. At higher pressures the gaseous reaction rate is enormously increased, whereas the rate of thermal decomposition is practically unaffected. The gaseous reactions, therefore, take control and burning proceeds smoothly and continuously.

He said that in Germany there was a complete mathematical theory of the burning of solid propellants in rockets, based on the reactions occurring in the gaseous phase.

He discoursed on the properties of propellants consisting of ammonium perchlorate bound with various plastic materials, either thermoplastic or heat irreversible materials. These, he claimed, gave no "liquid" layer on thermal composition.

A few small samples, which he possessed, were examined. They had not the appearance of colloidal propellants, but rather that of a consolidated material. Although they were hard, they were not brittle as would be expected, on striking with a hammer.

In replies to questions Dr. Teichmann claimed the following properties for these propellants.

A. Burning Characteristics

1. Stable burning at pressures from 20 to 700 atms.
2. Rate of burning could be varied over a wide range, by altering the composition, and could be made many times greater than that of normal colloidal propellants, even at low pressures.
3. Erosion effect was small at low pressures.
4. Smokeless.
5. Almost flashless, since combustion was practically complete, the products being N_2, H_2O, CO_2, HCl and a little CO.
6. Calorimetric value about 1000 cals./grm.
7. Performance index, 250.
8. Ignition presented no difficulties, owing to the reliability of burning at low pressures.
9. No erosion of the venturi had been observed after firing. It was his practice to use venturis of comparatively large throat diameter.

B. Physical Properties

1. Mechanical properties could be varied over a wide range from soft thermo plastic materials to hard infusible solids, depending, presumably, on the nature of the binder. (Teichmann would not say what plastics were used as binders).
2. S.G. about 1.8.

C. Charge Design

1. The thermoplastic propellants could be extruded at 120^{o}C. and used as sticks, or the more plastic varieties could be pressed into star centred charges adhering to the walls of the tube.
2. The rigid types could be cast and hardened either by warming or in the cold. He claimed good adhesion to steel even for these, and preferred the cast, cold hardening materials for large charges and the extruded thermoplastic varieties for small charges.

D. Storage and Safety

1. No deterioration either chemically or physically on long storage. Gassing did not occur below 180^{o}C.
2. Spontaneous ignition temperature, 270^{o}C.
3. Could be detonated by powerful initiation.

Dr. Teichmann said that development had not proceeded beyond the stage of static firings in vented vessels. His idea was to burn the propellant at lower pressures (300 lb./sq. in.) and thus increase the performance of the rocket by saving weight on the metallic components.

This team was not impressed by the mechanical properties of the samples of propellant examined, and doubted Teichmann's claim of good, permanent adhesion to steel. He appears, however, to have done a considerable amount of fundamental work on gaseous combustion, but this team was not sufficiently well acquainted with this field to be able to assess its value. [...]

[p. 30:]

Work on liquid fuel rockets had been confined principally to fundamental research, rather than to specific projects, although some routine work connected with development had been done. Dr. Sänger had not worked with solid propellants.

The object of the research was to increase the efflux velocity of the gases. Two methods had been investigated using the hydrocarbon/liquid oxygen system.

1. Increasing the heat content of the products of combustion (H_2O and CO_2) of the fuel by the dispersion in the fuel of certain light elements, e.g. Be, B, Li, Mg or Al.
2. The use of liquid ozone mixed with liquid oxygen.

[...] Sedimentation of dispersions of the aluminium in the hydrocarbon fuel (diesel oil) presented some difficulty, which was finally solved by stabilisation with oppanol (a hydrocarbon polymer). Sedimentation was then very slight after standing for one month.

The hydrocarbon/aluminium fuel gave rise to a large amount of white smoke from the rocket motor, as would be expected.

[Polybutadiene synthetic rubber was invented by German scientists in 1929–1930 (see pp. 656–657). Teichmann appears to have been working in this field of rocket propulsion since 1937.

This report also stated that aluminum powder was being used to increase the performance of large liquid propellant rockets, and even that highly novel chemical methods had been developed and demonstrated in order to keep the aluminum powder suspended in the liquid propellant for over a month during storage. While this report does not specifically mention the use of aluminum powder in large solid propellant rockets, it seems likely that that was done as well. For examples of other reports on the use of aluminum powder to improve the performance of small solid propellant rockets or closely related solid explosives in wartime Germany, please see the following reports.]

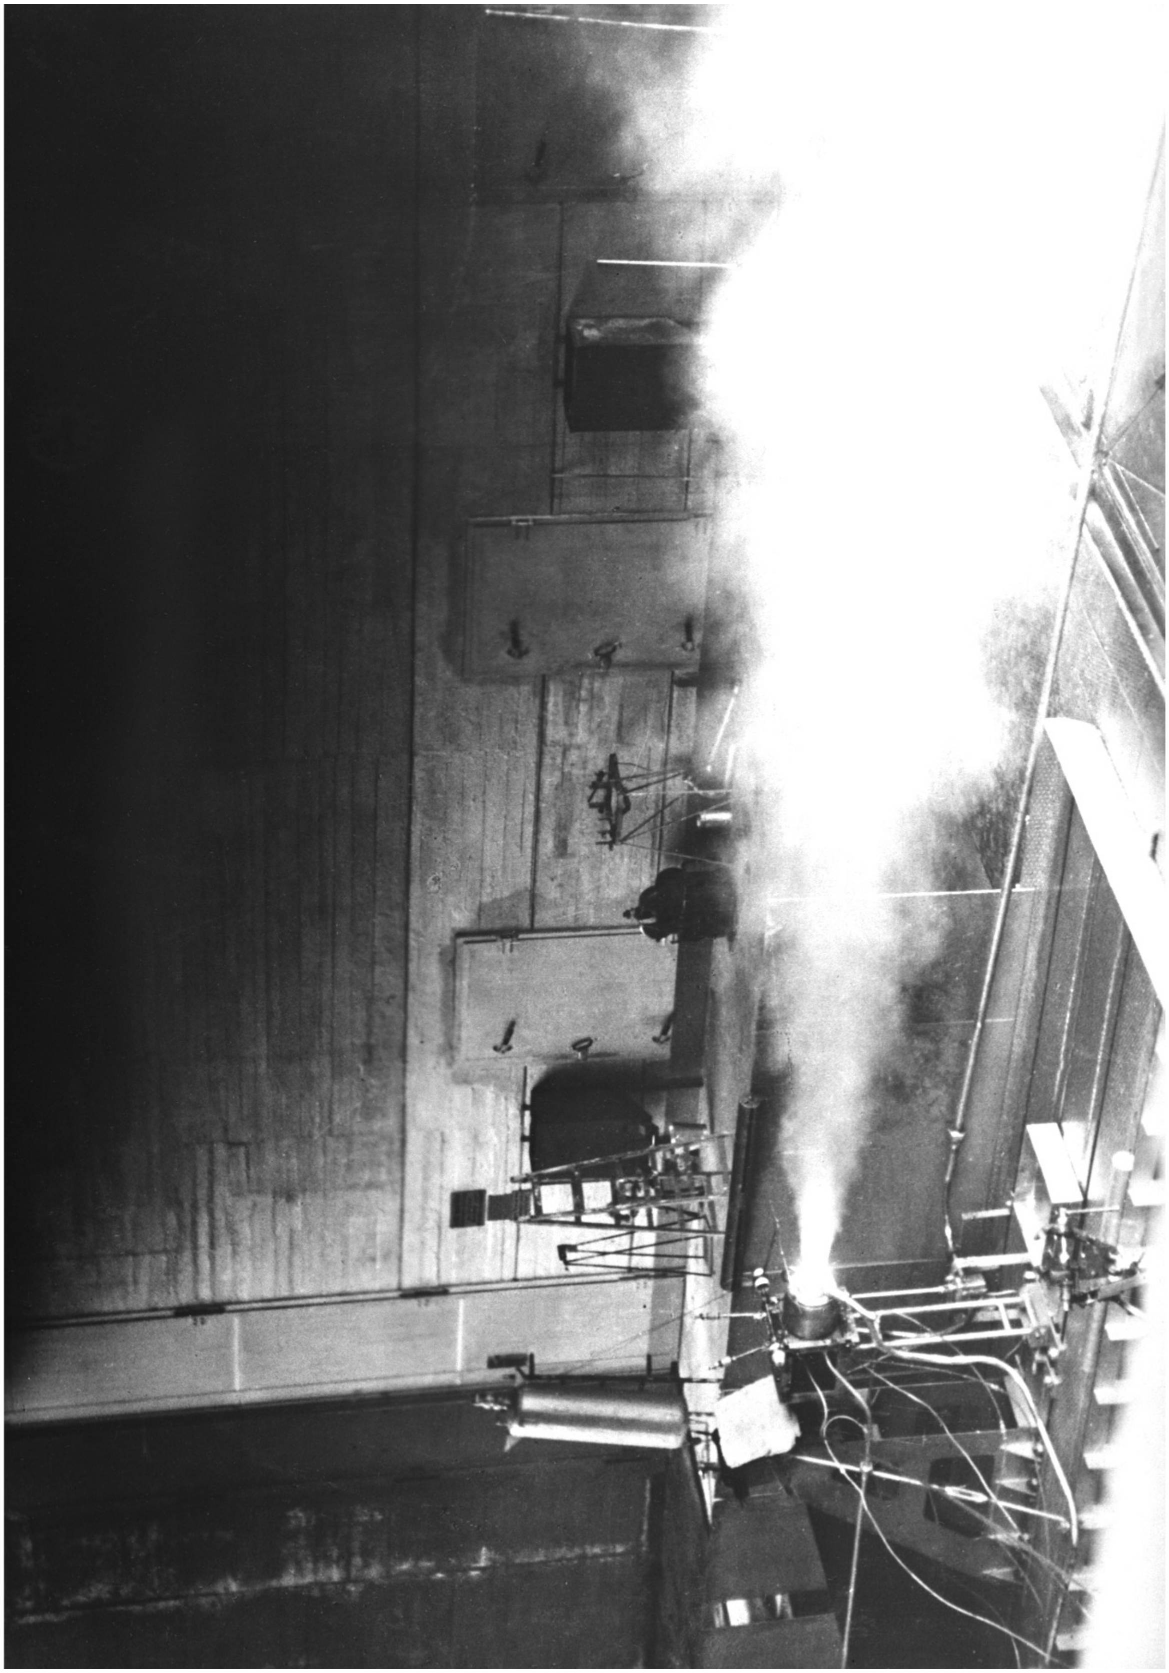

Figure E.229: 1941 test firing of one of Eugen Sänger's rocket engines using aluminum powder in the propellant mixture [Deutsches Museum Archive, photo 30389]

BIOS 27. ***Modern High Explosive Developments at Deutsche Waffen und Munitions Fabriken, A.G., Schlutup near Lübeck.***

The factory normally received its explosives already mixed in the form of lumps but Dr. Weidle had carried out a certain amount of research in order to determine the optimum proportions of the various ingredients. He found that 20 per cent aluminium mixed with 80 per cent of the hexogen/wax mixture gave the best blast effect in small light cased munitions. [...] Aluminium in flake form was used in the early days of development but had been abandoned in favour of granulated owing to difficulties in handling the former. [...] The size of the granulated aluminium used was stated to be all through a 0.15 mm aperture sieve. [...]

Production of the mixture was said to be carried out in the following way. The T.N.T. was melted in a steam kettle, dry hexogen added with stirring and finally the aluminium. 50 litre kettles were used and the mixture stirred by a conventional propeller stirrer.

(iii) and (iv) were used as poured fillings for hollow charge ammunition[...]

BIOS 1261. ***Visit to German High Explosive and Filling Factories.*** **pp. 9–10.**

The W.A.S.A.G., Allendorf, Kreis Marburg, Hesse was visited on 16.10.45. [...]

Dr. Walther Naumann, formerly a director of the factory, was available for interrogation and demonstration of sections of the plant required. [...]

When preparing hexanite/aluminium the T.N.T. was first melted and run into a jacketed stainless steel mixer. The aluminium was added next and the hexanitrodiphenylamine last. Similarly when preparing trialen 105 or 106 the T.N.T. was charged first, the aluminium next and then the hexogen. [...]

Dr. Naumann stated that larger mixing units than the type seen had been installed more recently, these having a capacity of 1000 Kg. as compared with the 400 Kg. units of the original plant.

With regard to the aluminium powder it was stated that two types were used viz. Pyro-schliff and Griess. The first of these was prepared by grinding and the second was a fine blown aluminium. Pyro-schliff was very dusty but was less inclined to sedimentation than the coarser blown powder. All the aluminium was specified to pass a sieve of 6400 meshes per sq. cm., approximately 200-mesh. A chemical specification was in existence but not available for inspection. The management were conscious of the risk of ignition of airborne fine aluminium powder through electrical agency and had in fact experienced two ignitions attributable to this cause. Owing to the provision of a simple drenching apparatus fitted to the mixing unit there were no serious consequences to these ignitions. The aluminium was fed to the pan through a stainless steel funnel attached to the pan-cover and fitted with a wide skirt which directed the aluminium against the wall of the pan, the object being to remove as much as possible of any accumulated static charge on the powder.

BIOS 100. *Development of Panzerfaust.* pp. 10–11.

Langweiler appeared to attach more importance to the flame effect behind the target than the remaining power of the jet itself. The enhancing of this flame effect was in his opinion the most likely method of increasing the efficiency of hollow charges. This effect could be increased very greatly by incorporating into the H.E. charge up to 30% of powdered aluminium. This proportion could be used without impairing performance. Had it not been for the great shortage of aluminium in Germany this type of filling would have been used in Panzerfaust.

NavTecMisEu 327-45. *Solid Rocket Propellant. Translation of a Report by Dipl. Ing. Hans Grosse.* p. 14. [NARA RG 38, Entry P5, Box 46]

In general black powder was used as an auxiliary charge. Black powder causes a relatively slight ignition delay, however, is sensitive to moisture and as far as transportation is concerned, and increases the creation of smoke. In cold temperatures, furthermore, it does not always give a sufficiently intensive ignition, especially in the case of long charges. Therefore, besides black powder, boosters were also used. These consist of mixtures of a composition similar to that of flash light powder for photographic purposes, i.e., light metal dust, Al., Mg., together with salts giving off oxygen, such as potassium nitrate, barium nitrate, etc. These mixtures are firmly pressed in capsules of aluminum, lately also of cardboard. They produce, especially at low temperatures, a very hot flame and thus avoid ignition failure in this temperature range. At high temperature they do not effect such a great increase in gas pressure as does a black powder auxiliary charge of an equally strong ignition effect, because they develop relatively little gas.

HEC 2434. German patent D70226. Use of black powder for rocket propulsion, containing metal sulfides and/or metal alloys which give off oxygen on heating.

HEC 2485. Propellant for rockets which discharges vapours of metals or their salts.

HEC 2487 = HEC 2468. Powdered metals as ingredients of rocket propellants.

[...] The following persons were interviewed at the Czech War Office:

[...] Dr. W. Voss	[...] Head of Waffen Union
[...] Ing. K. Staller	[...] Deputy to Dr. Voss
Ing. Musel	Managing Director, Zbrojovka
Ing. S̆idlék	Czechomoravian Engineering Works
Dr. Frey	Jawa

[pp. 29–32:]

EXPERIMENTAL STATION AT PRIBRAM

[...] The preliminary work for the formation of the station was started late in 1943 and it was not until the early summer of 1944 that the staff commenced serious work. [...]

There is a fact which should be noted. When the buildings were visited in late November, they were completely stripped and only one engineer and a woman secretary left in charge. In answer to the query as to what had happened to the library, equipment and staff it was stated that the Mining Institute had been removed to Moravaka Ostrava and the scientific staff had returned to Charles University, the technical schools and firms from whom they had come originally. It is remarkable that a move of some magnitude involving a journey from the west side of Bohemia to the Eastern frontier should have been carried out with such completeness within six months of the end of the war in Europe considering the difficulties of road and rail transport during this period.

[...] Staff. The strength of the Institute was 350. This figure includes workmen as well as the higher staff. Skoda and Zbrojovka contributed engineers and designers, whilst the scientific staff was recruited from the Universities and technical schools.

The card index covering the whole of the staff was produced for inspection at Pribram. A cursory examination of the cards revealed a fair percentage of German staff[...]

The following details of some of the personnel were compiled from the card index and other sources. [...]

Engel, Rolf. Born in 1912. Came from the research institute at Grossendorf and arrived at Pribram on 23.7.44 to take charge of a section. A Diploma Engineer and a physicist. Later he took charge of the whole Institute. Stated to be a most able engineer and mathematician. Was Hauptsturmführer in the S.S. Escaped to Germany and was last heard of south of Munich. [...]

Bödewadt. Dr. Born 1911 at Essen. Came from the research institute at Grossendorf and was chief of ballistics. He escaped. [...]

Teichmann, Hermann. Dr. Born 1913. A doctor of engineering who worked on explosives and also did administration. Escaped.

Schmidt, Kurt. Dr. Born 1912. Also an engineer. Worked on chemical research.

Schmidt, Walter. Dr. Head of the Chemical Department and came from the Waffen-Union. Held in prison at Pribram.

Bock, Helmuth. Born 1923. A machine designer in the technical section.

Nordt, Dr. Worked on explosives. Escaped. [...]

Seifert, Hugo. Ing. In charge of the workshops. Imprisoned at Pribram.

Kucera. Leader of Werkschutz. Imprisoned at Pribram.

Larsson. A Swede engaged on the study of rockets.

Votruba, Karel. Dr. Ing. Was chief of the high frequency group. A Czech and now with VTR research.

Simon, Inval. Dr. Czech. Chief of the low frequency group. Now back at Charles University, Prague.

Truha, Zdenek. Dr. Ing. Czech. Chief of the section dealing with long distance control and measuring. Now working in a technical school in Prague.

Broz, Jaroslav, Dr. Czech. Head of the magnetic section. Now with VTR research.

Jahoda, Dr. Czech. Manager of range laboratories at Drahelcice.

Zbozinek, Arnost, Ing. A Skoda man and head of the general design. Now working in the national administration at Klastenec Nad Ohri.

Stelsovsky, Jan. Ing. Czech. Head of the rocket design section. Is now in the Czech Army.

Sternad, Dr. Czech. Born 1912. A Skoda man who worked in the physics section at Pribram. Considered one of the more outstanding technical men.

Kalendovsky, Dr. Czech. Born 1911. Worked as an engineer.

Buresova, Florentine, Ing. (Woman). Born 1922. A German chemical research worker.

Behounek, Dr. Ing. No other information other than that he is under interrogation as as doubtful Czech.

Knust, Dr. Born 1915. A chemist and belonged to the S.S. A German.

Odstracil, Ing. Czech. An engineer and scientist employed by Zbrojovka.

The above particulars are in many cases very sketchy, indeed some are just the bare facts taken from the card index. In others this information has been supplemented. [...]

[p. 42:]

The purpose of the institute was to prepare the documentation for production and to make prototypes of new products included into the manufacturing programme of the company Waffen Union. It was engaged in the study of rockets, especially from the theoretical point of view and therefore preparatory tests were carried out. As an example of the research work we are stating the high frequency transmission for transmitting the shooting elements at a distance of 10 km., stabilization device for shooting from tanks by means of a telescope on a gyroscope, simultaneous aiming and directing of a number of machine-guns, study of directing the rockets by means of infra red rays.

[p. 68:]

Baubin. Was permanent secretary of Skoda. A member of the S.D. [...]

Staller, Karel Ing. Acted as deputy to Voss but worked in the resistance movement and has been cleared of suspicion of collaboration. He has been given a certificate from Czech General Headquarters to this effect. One of the most able engineers in Czechoslovakia. Sent over 120 engineers and designers to Allies, as well as machine tools. [...]

Voss, Wilhelm, Dr. Born 1896. A jurist and accountant. Came from Rostock Mecklenberg and was educated at the Universities of Berlin and Leipzig. Trained as an accountant and worked in an agricultural organisation and the legal branch of an insurance company. Visited England in 1926 and read paper to an international congress of accountants. Joined the Nazi party in 1937. Was appointed in 1938 as General Director of Administration and Commerce in the Hermann Goering Trust in Berlin and in 1939 came to Prague.

Differences with Pleiger caused Goering to form the Skoda Brünn Waffen Union and Voss put in charge. He was dismissed in January 1945 as unsatisfactory. Now in prison in Prague.

[Despite the deep involvement of Hans Kammler and Erich Purucker with these facilities and programs, all mention of them has been carefully omitted from this BIOS report (compare with the information on p. 4914). Likewise all mention of nuclear-related work has been carefully omitted (compare with pp. 3751–3754).]

Tom Bower. 1987. *The Paperclip Conspiracy: The Hunt for the Nazi Scientists.* Boston: Little, Brown. p. 151.

Rolf Engel, an SS officer who during the war had supervised the production of solid-fuel rockets at a Skoda plant in Czechoslovakia, was recruited by French agents while hiding in the American zone, fearing arrest for his wartime activities.

[Rolf Engel, Uwe Bödewadt, and Hermann Teichmann all went to work for France after the war (p. 1883). Information on their postwar contributions is not publicly available, but presumably they were instrumental in developing modern solid propellant missiles and rockets in France, and they may have made important contributions in other areas—such as nuclear weapons—as well.]

Jan Kotůlek. František Čuřík (†June 7, 1944): The First Professor of Mathematics and Descriptive Geometry at Mining University (VŠB).
[http://homel.vsb.cz/~kot31/Veda/23-3mi-s71-76Kotulek.pdf]

[...] Some of his colleagues from VŠB promoted the story that František Čuřík was forced by the Nazis to collaborate in their company Waffen-Union research institute in Příbram (contemporary German name of the town was Pibrans) on the ballistic computations of missiles V-2. He resolutely refused it as treason and, because he could not see any other way out of this situation, he took his own life, cf. [7].

However, the story is probably only partially based on the truth. The holding company Waffen-Union Skoda-Brünn worked in weapon industry within the concern Reichswerke Hermann Göring. The top management was exclusively German, but research divisions were under Czech governance, mathematical research division was led by Miloslav Hampl (1897–1974) and physics division by Professor Václav Dolejšek (1895–1945), who handed his responsibilities to dr. Miloslav Tayerle during 1940. Tayerle should have set up the research institute of Waffen-Union in Příbram. He brought his collaborators from Skoda, hired some researchers from Zbrojovka Brno (Brünn) and counted also with some professors from the closed VŠB in Příbram. Their names are listed in the report about the visit of the Mining University from October 9 1943: Jirkovský, Šebesta, Čechura, Glazunov and Mitinský. František Čuřík, then already pensioned for three years, was not considered. However, in this period, there was also no rocket research.

The situation changed rapidly in August 1944, when SS-Hauptsturmführer Rolf Engel, head of the Versuchsanstalt für Strahltriebwerke in Grossendorf, evacuated his institute from West Prussia to the Protectorate of Bohemia and Moravia and overtook the governance of the research facilities in Příbram. He had already worked intensively in the rocket research for SS and he strictly opposed the German army project of V-2, cf. [6]. When Engel came to Příbram, Čuřík was already dead. But even if Engel had looked for collaborators in the spring 1944, he would not have chosen Čuřík. Ballistics was a key discipline, controlled entirely by the Germans, and Engel had his own mathematicians with expertise in ballistics, namely Dr. Uwe Tim Bödewadt (1911–2003), Dr. Franz Kalscheuer (1913–2002), Niels W. Larsson or H. Teichmann, see [3].

MEMORANDUM FOR DIRECTOR OF INTELLIGENCE, WDGS:
(Attn: Special Exploitation Branch)

SUBJECT: Assembling Certain German Scientific Personnel for Interrogation

1. This Headquarters has been advised by Dr. F. Zwicky, Director of Research, Aerojet Engineering Corporation, and Colonel R. L. Wassell, Power Plant Laboratory, Engineering Division, through Air Materiel Command, of the necessity of obtaining information and reliable data in the fields of thermochemistry and kinetics of chemical reactions to round out information obtained by them in Germany in 1945. Basic knowledge in these fields is considered of prime importance for future progress in jet propulsion. It is felt that much of this data may be obtained from interrogating German scientific personnel now in Germany. Since Dr. Zwicky was going to Paris to attend the conference on applied mechanics in September, and Col. Wassell is scheduled to go to Germany about the same time, it was suggested by Wright Field that they plan on going over in August to accomplish the mission of obtaining this information for T-2. Dr. Zwicky assented to this proposition and has furnished the names of the scientists he thinks should be contacted. This list is enclosed herewith.

2. It is requested that the necessary action be taken to locate the scientists listed and that arrangements be made to assemble them in two or three locations so that they may be conveniently interrogated. The actual date of assembly will be furnished by this Headquarters as soon as the proposed date of departure of Dr. Zwicky and Col. Wassell is known. It will be necessary, however, that this matter be given expeditious handling in order that this may be accomplished the first part of August.

FOR THE COMMANDING GENERAL:

Figure E.234: 16 July 1946 list of German scientists to be interrogated by Fritz Zwicky. [NARA RG 319, Entry NM3-47B, Box 991, Folder 400. 112 Research/009. 14 May 1945]

[Fritz Zwicky (Swiss, 1898–1974) moved to the United States in 1925, part of the wave of German-speaking scientific immigrants who came before the Third Reich. He recruited additional German-speaking scientific immigrants during and after the Third Reich and directly assisted the U.S. government in transferring as much scientific knowledge as possible out of the German-speaking world. While Zwicky is best remembered as an astrophysicist, he was keenly interested in all forms of aerospace propulsion and greatly aided the United States in that area. He was a professor at Caltech but also a research director/scientific advisor at Aerojet 1943–1961. Zwicky was deeply involved in scientific interrogations after the war in 1945, and this memo shows that in 1946 he was still interrogating large numbers of German-speaking scientists. He made the interrogations listed in this memo on behalf of Aerojet.

Although the memo said the list was aimed at "thermochemistry" or "jet propulsion," the listed scientists (and the interrogations that they were probably subjected to) covered a far broader range of fields. For example, many scientists on this list were primarily nuclear experts—Klaus Clusius, Max Volmer, Paul Harteck, Wilhelm Groth, etc. A few names on the list were underlined, and the memo noted: "Those whose names are underlined, have been working recently in the fields of our special interest." One of the underlined names was Paul Harteck. Was that unnamed "special interest" simply thermochemistry, or some other topic, such as heavy water production or uranium isotope separation? Was this "thermochemistry" memo an umbrella for a much broader and multipurpose series of scientific interrogations by the United States?

This memo demonstrates just how dependent the United States was on German-derived scientific knowledge. It emphasized how much important information was obtained "in Germany in 1945." Then it stated that it was "considered of prime importance for future progress" to obtain even more information, and that "this data may be obtained from interrogating German scientific personnel now in Germany" during 1946. The United States needed to transfer large amounts of scientific information and scientific personnel from the German-speaking world, and even that transfer process itself was directed by U.S. representatives such as Fritz Zwicky and Theodore von Kármán who were themselves German-speaking scientists.

Hermann Teichmann, who invented and demonstrated ammonium perchlorate/polybutadiene solid rocket propellant, was especially singled out on this list. The document gave more information about him than any other scientist on the list, and he was the only scientist for which it was specifically stated, "It is important to find" him. Apparently either Fritz Zwicky had been directly involved in interrogating Teichmann in 1945, or else Zwicky had read detailed reports on those interrogations (such as the other documents quoted in this section). Teichmann eventually ended up working for France. It is unclear from this and other available documents if Zwicky actually did interrogate Teichmann in 1946, but it seems evident that Zwicky and his employer Aerojet were keenly interested in and highly knowledgeable about Teichmann's revolutionary work on solid propellant rockets.

Presumably based on such information, in 1948 Aerojet began producing ammonium perchlorate/polymer propellants, and it even hired German-speaking scientists such as Karl Klager to perfect those propellants, along with the continuing guidance of Zwicky. Please see the following documents for more information.]

Donald L. Putt to Curtis B. LeMay. 23 January 1946. SUBJECT: Research and Development of Solid Fuel Rockets. [AFHRA folder 201-56 Vol. 1 Pt. 2 May 1945–Mar 1947; AFHRA A2055 Frames 1109–1110]

SUBJECT: Research and Development of Solid Fuel Rockets

TO: Commanding General
Army Air Forces
Washington 23, D.C.

Attn: Major General Curtis B. LeMay
Deputy Chief of Air Staff for
Research and Development

1. It is understood that your office has recently received a communication setting forth the need for reviving research on solid fuel rockets.

2. For such use as can be made of the information, it is desired to present the following:

a. German aeronautical research establishments and industry have spent years working on subject development. It is believed that the Germans were considerably advanced beyond our own efforts in this field. Most of the documentary information covering this past research is available in the Air Document Division, Wright Field.

b. Every effort should be made to take advantage of this work which has already been done so as to profit from the mistakes made by the Germans and to prevent costly duplication of effort in repeating work already done.

c. There are presently stationed at Wright Field several German scientists who have worked in the rocket field. One scientist in particular has done research work on solid rocket fuels and motors for the past ten years. Another was instrumental in the development of the motor and liquid fuels for the ME-163. Both have plans and ideas for further research which would lead to improved fuels and increased efficiencies of rocket motors. Every effort should be made to provide means and facilities to acquire the projected thinking and plans of these scientists to assist and expedite our own research and development to the greatest possible extent.

d. These scientists are not now and can not be effectively and efficiently utilized at Wright Field, due to the current restrictive regulations governing the exploitation of German scientists, which, in the opinion of this office, have no sound or logical basis. Nearly all of the rocket motor and fuel research work has been done by agencies outside of Wright Field, such as N.A.C.A., California Institute of Technology and Monsanto Chemical Company. The regulations prohibit any contact between German scientists and those institutions, to whom they could be of great benefit. Certainly there can be no sound basis for prohibiting companies having contracts with the Army Air Forces or other Government agencies to interview German scientists at Wright Field to obtain their advice and assistance in furtherance of their Government contracts. This procedure would likewise bolster the morale of the German scientists and eliminate their complaint of having to live in a “scientific desert", which is occasioned by a complete lack of contact with people on the same scientific level.

3. Any assistance which your office might render to obtain a revision of regulations which would permit a full and complete utilization of the German scientists now in the United States would materially aid and benefit our own research and development program, not only in the field of rockets but in those of guided missiles, supersonics, jet engines and jet aircraft.

FOR THE COMMANDING GENERAL,

D. L. Putt
Colonel, Air Corps
Deputy Commanding General
Intelligence (T-2)

[At this point, by the year after the war, Donald Putt arguably had the best understanding in the world of all the rocket-related accomplishments up to that time both in Germany and in the United States. From that well-informed vantage point, Putt clearly stated that "the Germans were considerably advanced beyond our own efforts" on "solid fuel rockets." To back up that assertion, he explicitly said that he had "documentary information covering this past research" stored at the Wright Field Air Document Division, and that he also had under his direct supervision scientists with up to ten years of previous experience on solid propellant rockets in Germany. From his wartime and postwar jobs, Putt would also have been intimately familiar with other relevant evidence, scientists, and projects throughout Germany and the United States.

At the time of Putt's memo, Wolfgang Noeggerath was at Wright Field [e.g., AFHRA A2055 Frame 1165]. During the war, he had worked on hypergolic liquid propellants for the Me 163 rocket plane and other vehicles [John Clark 1972, pp. 13–17], so he appears to have been the second scientist that Putt referenced. Putt's memo succeeded in getting the German scientists to the U.S. programs that needed them, and Noeggerath became the lead scientist for the first U.S. solid propellant, submarine-launched ballistic missile, Polaris (p. 5722).

The first scientist that Putt referenced, someone who already had a decade of experience developing solid rocket fuels and motors, may have been Gerhard Braun, Rudolf Edse, or another German or Austrian expert who was at Wright Field at that time [e.g., compare p. 1906 and AFHRA A2055 Frame 1165]. Future scholars should delve much further into the wartime and postwar work of these and other German-speaking scientists.

Note that in addition to direct work credited to the German scientists, Putt also specifically mentioned the quiet transfer of their knowledge and ideas to U.S. scientists and organizations. Therefore the actual contributions and true impact of the German-speaking creators were probably far larger than what the preserved documents show.]

Figure E.235: Donald L. Putt to Curtis B. LeMay. 23 January 1946. SUBJECT: Research and Development of Solid Fuel Rockets. [AFHRA folder 201-56 Vol. 1 Pt. 2 May 1945–Mar 1947; AFHRA A2055 Frames 1109–1110]

J. D. Hunley. 1999. The History of Solid-Propellant Rocketry: What We Do and Do Not Know. AIAA paper 99-2925. [Hunley 1999; https://doi.org/10.2514/6.1999-2925]

Integral to the stories of the propellants used on large rockets and missiles, smaller tactical missiles, and a host of smaller rockets for a variety of rockets and spacecraft were the various binders, fuels, and oxidizers that went into the propellants. For example, the motors for the Polaris A1 missile designed by Aerojet featured a cast, case-bonded polyether-polyester-polyurethane composition with 15 percent aluminum and ammonium perchlorate. Karl Klager at Aerojet has been credited with being largely responsible for developing both the grain and the propellant for these motors, but the story of their development is evidently quite complex. Klager received the U. S. Navy Distinguished Public Services Award in 1958 for his work on the Polaris missile, but the development of some of the propellant ingredients predates when Klager joined Aerojet in 1950. [...]

Karl Klager, who is credited with the development of HTPB [hydroxyl-terminated polybutadiene], was asked how he came to develop this low-cost, low-viscosity propellant that has become an industry standard. He said only that he started development in 1961 but waited until 1969 to propose the propellant to NASA for the Astrobee D and Astrobee F sounding rockets on which it flew successfully. Perhaps, however, Klager's response regarding how he came to discover unsymmetrical dimethylhydrazine (UDMH) (which is a liquid propellant used on the Bomarc missile, Titan 2 missile, Titan 3 and Titan 4 rockets, and other missiles and rockets) applies equally to HTPB. Klager said that he simply brought his knowledge of the science of chemistry to bear on the need for a propellant. He had earned a Ph.D. in chemistry from the University of Vienna in 1934 and had worked for several chemical firms in Europe from 1931 to 1948 before moving to the United States and starting work for Aerojet in 1950.

[Although aerospace historian J. D. Hunley focused mainly on the work of American engineers in the above paper and in the following book, he could not avoid mentioning the important contributions of Karl Klager (Austrian, 1908–2002) to the development of large solid-propellant rockets in the United States after the war.]

J. D. Hunley. *Preludes to U.S. Space-Launch Vehicle Technology: Goddard Rockets to Minuteman III.* [Hunley 2008a]

[pp. 154–156:]

Meanwhile, the first known castable solid propellant was the composite developed by John Parsons at the Guggenheim Aeronautical Laboratory at Caltech back in 1942 for use in JATO motors. Containing asphalt as a binder and potassium perchlorate as an oxidizer, this propellant—known as GALCIT 53 after the lab's acronym—did not have a particularly impressive performance compared, for example, with the double-base composition called ballistite. But it retained its performance at temperatures down to 40^oF far better than the compressed black powder Parsons had been using in JPL's JATO motors. At lower temperatures, however, GALCIT 53 cracked. It also melted in the tropical sun and was very smoky when burning. This last characteristic limited the takeoff of follow-on aircraft using JATO units on a single runway because the smoke restricted visibility. These shortcomings led researchers at GALCIT and its successor, JPL, to search for an elastic binder with storage limits beyond GALCIT 53's extremes of -9°F and 120°F. In particular, a young engineer named Charles Bartley, who was employed at JPL from June 1944 to August 1951, began examining synthetic rubbers and polymers, eventually hitting upon a liquid polysulfide compound designated LP-2, which worked as as solid-propellant binder. It was made by the Thiokol Chemical Corporation for sealing aircraft tanks and other applications. [...]

Before learning of LP-2, Bartley and his associates at JPL had tried a variety of moldable synthetic rubbers to use as binders and fuels, including Buna-S, Buna-N, and Neoprene. Neoprene worked best, both as a binder and as a fuel, but molding it required high pressures, like the extrusion process used with double-base propellants, which made the production of large propellant grains impractical. [...]

With encouragement from Army Ordnance and the Navy, Bartley—joined by John I. Shafer, a JPL design engineer, and H. Lawrence Thackwell Jr., whose expertise lay in aircraft structures—began in 1947 to develop a small rocket designated Thunderbird, which had a 6-inch diameter. The three researchers used it for testing whether polysulfide propellants could withstand the forces of high acceleration that a large launch vehicle might also encounter. [...]

Combining a polysulfide propellant with the star design and casting it in the case so that a bond formed, the team under Bartley produced the successful Thunderbird rocket that passed its flight tests in 1947–48.

While this rocket was being tested, another significant development for composite propellants was occurring—the replacement of potassium perchlorate by ammonium perchlorate, which offered higher performance and less smoke. [...] Already in 1947, however, JPL had developed a propellant designated JPL118 that used only ammonium perchlorate as an oxidizer together with polysulfide as the binder and couple of curing agents. Although this propellant had yet to be fully investigated in 1947, by mid-1948 it provided a specific impulse of 198 lbf-sec/lbm at sea level using an expansion ratio of 10 for the rocket nozzle. [...]

Aerojet likewise began using ammonium perchlorate in its Aeroplex (polyester polymer) propellants in 1948 in order to increase specific impulse and reduce smoke. Funded by the Navy Bureau of Aeronautics to develop a basic understanding of the production and employment of solid propellants, Aerojet increased the specific impulse of its ammonium perchlorate propellants to 235 lbf-sec/lbm, but its Aeroplex binder was not case bondable, leading the firm to switch in 1954 to a polyurethane propellant that was.

In the interim, Thiokol sought to sell its polymer to Aerojet and another manufacturer of rockets, the Hercules Powder Company, but both rejected Thiokol's product because its 32 percent sulfur content made it a poor fuel. [...]

[p. 295–296:]

It was not ARC's polyvinyl chloride, however, that served as the binder for Polaris. Rather it was a polyurethane developed by Aerojet. This development began under a small Navy nitropolymer program funded by the Office of Naval Research about 1947 to seek high-energy binders for solid propellants. A few Aerojet chemists synthesized a number of high-energy compounds, but the process required levels of heating that went beyond what was safe for potentially explosive compounds. Then one of the chemists, Rodney Fischer, found "an obscure reference in a German patent" suggesting that "iron chelate compounds would catalyze the reaction of alcohols and isocyanates to make urethanes at essentially room temperature." This discovery started the development of polyurethane propellants in many places besides Aerojet.

Meanwhile, in 1949 Dr. Karl Klager, then working for the Office of Naval Research in Pasadena, suggested to Aerojet's parent firm, General Tire, that it begin work on foamed polyurethane, leading to two patents held by Klager with Dick Geckler and R. Parette of Aerojet. In 1950 Klager, who had earned a Ph.D. in chemistry from the University of Vienna in 1934 and had come to this country as part of Project Paperclip, began working for Aerojet. By 1954 he headed the rocket firm's solid-propellant development group. Once the Polaris program began in December 1956, Klager's group decided to reduce the percentage of solid oxidizer as one component of the propellant by including oxidizing capacity in the binder itself, using a nitromonomer as a reagent to produce the polyurethane plus some inert polynitro compounds as plasticizers, or softening agents. [...T]hey came up with successful propellants for both stages of Polaris A1.

These consisted of a cast, case-bonded polyurethane composition including different percentages of ammonium perchlorate and aluminum for stages 1 and 2, both of them featuring an internal-burning six-point star configuration.

[p. 396:]

10. [...] According to Fuhrman, "Polaris to Trident," 12, "Tests at the Naval Ordnance Test Station in 1955, which were confirmed by the Atlantic Research Corporation in 1956, demonstrated a significant increase in specific impulse obtained by the addition of finely divided aluminum to the propellant."

11. [...] For his work in developing both the grain and the propellant, Klager received the Navy's Distinguished Public Service Award in 1958[...]

[p. 319:]

The Minuteman team delivered the first Minuteman I to the Strategic Air Command in October 1962, almost exactly four years after the first development contracts were signed. [...]

The first stage, developed and produced by Thiokol, included a new propellant binder developed by the company's chemists between 1952 and 1954.

[...] Thiokol added 10 percent acrylonitrile to the PBAA, creating polybutadiene-acrylic acid-acrylonitrile (PBAN). The binder and curing agent constituted only 14 percent of the propellant, with ammonium perchlorate (the oxidizer) and aluminum (the major fuel) being the two other main ingredients.

[A] Teflon-coated mandrel created the tapered six-point star that formed the internal-burning cavity. [...]

[...] V. POLYMERIC BINDERS [...]

C. POLYSULFIDES

In the latter stages of World War II, SRM binder work for JATOs led to the use of a styrene-butadiene rubber, Buna-S, developed by IG Farben in Germany before the war. Although Buna-S performed well over a broad temperature range, dewetting of the motor grain from the case proved an insurmountable problem. Adhesion at the motor's bond line is critical because the debonded surface of the grain will burn prematurely, causing motor failure. [...]

D. PLASTISOLS

[...] Plastisol nitrocellulose (PNC), sometimes called "spheroidal" or "pelletized" nitrocellulose, was developed at ARC and also featured a long pot life, although not as long as PVC's. PNC used NC nitrated at 12.6%, dissolved in nitromethane and ethyl centralite, and emulsified in water. The nitromethane was then leached out and 5–50 micron spheres collected by centrifugation. While used sparingly in SRM, PNC was employed in warheads and gun propellants. The U.S. Navy deemed PNC important enough that it manufactured the material itself at the Naval Propellant Plant in Indian Head, Maryland, starting in 1958. Production ended when accidents forced closure of the facility in the 1990s.

E. POLY(BUTADIENE-ACRYLIC ACID)

In the mid-1950s, butadiene-containing copolymers reappeared with poly(butadiene-acrylic acid; PBAA), a random copolymer developed as a binder by Thiokol at Redstone Arsenal. PBAA had a molecular weight of about 3000 Da, but being made by free radical emulsion polymerization, it was a mixture of various polyfunctional chains, including some nonfunctional, resulting in poor reproducibility. Crosslinking was carried out by ring opening of difunctional epoxides and aziridines by the acrylic acid groups. Although the prepolymer had a sufficiently low viscosity to allow high solids loading, the resulting crosslinked polymer had poor mechanical properties because of the irregular network structure and for this reason was abandoned. However, PBAA was used by Thiokol as the binder for the first stage of the Minuteman I ICBM. [...]

H. HTPB

Hydroxyl-functionalized prepolymers had been combined with multifunctional isocyanates in the early 1950s, even before the introduction of PBAN and CTPB. General Tire & Rubber experimented with urethane crosslinked polyethers and polyesters for propulsion formulations as early as 1947. However, it was Aerojet that had the initial successes with these materials under the leadership of Karl Klager, an Austrian chemist who had worked for IG Farben during the Second World War and was brought to the United States by the U.S. Office of Naval Research under Operation Paperclip in 1949. Klager's polyurethanes were used in both stages of the Polaris A1 and in the second stage of the Minuteman I. These materials were a combination of poly(1,2-propylene oxide) (PPG) and poly(1,4-tetramethylene oxide) (PTMEG), cured with toluene diisocyanate and crosslinked with triethanolamine. Other examples of such binders included poly(ethylene oxide) (PEG), poly(neopentylglycol azelate), and poly(butylene oxide); commonly referred to as B-2000.

These types of binders had excellent stability, mechanical properties, and reliability for their era but nevertheless were passed over in favor of CTPB-based formulations.

So dominant was CTPB throughout the 1960s that although HTPB was first synthesized for use in binders in 1961, it did not see actual use in a rocket motor until 1968, when Aerojet used it in a dual-thrust radial-burning motor grain formulation for the Astrobee D, a NASA-sponsored meteorological sounding rocket. Gradually, HTPB gained widespread use as a replacement binder in older systems employing CTPB, for example, in the Maverick, Stinger, and Sidewinder missiles. After 50 years of use, HTPB remains the standard binder for nearly all U.S.-made SRM. HTPB-based polyurethane binders are relatively inexpensive, have low viscosity prepolymers, and exhibit good mechanical and aging properties. The binary system enables a high solids content, providing one of the highest specific impulses among solid propellants. [...]

VI. ENERGETIC POLYMERS [...]

A. POLY(GLYCIDYL NITRATE)

In 1953, formulators at the U.S. Naval Ordnance Test Station in China Lake, California, synthesized 800 to 3400 Da poly(glycidyl nitrate; PGN) using stannic chloride as a catalyst[...]

[Karl Klager had a huge number of patents on solid and liquid rocket propellants—see for example Figs. E.236–E.242.

The above article specifically credits some of the contributions of Karl Klager, but likely there were many other contributions from the German-speaking world to postwar solid propellant rockets. After the war, U.S. aerospace laboratories in places such as Redstone Arsenal, China Lake, and Indian Head were filled with German-speaking scientists, German-produced hardware, and German-derived documents and technical information. If many of these solid propellant innovations were not derived from German work, why were they not developed by the United States during World War II, before the German-speaking scientists and information arrived, when the United States had great need for such technologies in the war? It would be useful for future historians to search for specific people, paper trails, and other links connecting wartime German work on solid rocket propellants and postwar U.S. work on such propellants.]

3,214,474
PREPARATION OF UNSYMMETRICAL HYDRAZINES
Karl Klager, Monrovia, Calif., assignor to Aerojet-General Corporation, Azusa, Calif., a corporation of Ohio
No Drawing. Filed Sept. 28, 1953, Ser. No. 382,828
6 Claims. (Cl. 260—583)

This invention relates to an improved process for preparing unsymmetrical alkyl hydrazines.

Unsymmetrical alkyl hydrazines have been known for many years and their properties as fuels have been well recognized in the art. However all of the known processes for their production produce poor yields of low purity. Accordingly, the use of alkyl hydrazines as fuels, in particular as propellant fuels, has been somewhat restricted for economic as well as for safety reasons, since a high degree of purity is required for this use in order to lessen the possibility of explosive reactions.

It is an object of this invention to provide an improved method for the preparation of unsymmetrical alkyl hydrazines which will provide increased yields of greater purity.

Classically unsymmetrical alkyl hydrazines are prepared by the reduction of nitroso dialkylamines. This reaction proceeds in accordance with the reaction scheme set forth below:

$$\overset{R}{\underset{R'}{>}}N{-}NO \xrightarrow{[H]} \overset{R}{\underset{R'}{>}}N{-}NH_2$$

wherein R and R′ are the same or different alkyl radicals. However, it is known that the hydrazine bond may be dissolved under reductive conditions, this reaction taking place according to the following reaction scheme:

$$\overset{R}{\underset{R'}{>}}N{-}NH_2 \xrightarrow{[H]} \overset{R}{\underset{R'}{>}}NH + NH_3$$

where R and R′ are the same as above.

Hence it becomes apparent that a catalyst or set of reaction conditions which favors the former reaction and disfavors the latter will result in a successful method for the preparation of such substituted hydrazines.

Alkyl hydrazines have been prepared by reducing the nitroso group in the classical manner with zinc and acetic acid, however these conditions usually result in a complicated work up, a yield of approximately 65%, and in a product of relatively low purity.

In recent years it has been found that lithium aluminum hydride may also be employed to effect this reaction. However the lithium aluminum hydride method is very expensive, ordinarily yields a product of low purity and generally provides a theoretical yield of only about 75%.

We have discovered that by using palladium catalysts to effect the reduction, a yield of approximately 85% of the theoretical may be obtained and that the product thus obtained possesses a high degree of purity. Suitable palladium catalysts are: palladium charcoal, palladium-calcium carbonate and palladium-barium sulfate. Colloidal palladium may also be used as well as finely divided palladium on carriers such as silica gel, infusorial earth, alumina and other commonly used catalyst carriers. Because of these improved results, this method is applicable to large scale production with considerable decrease in the overall cost of production. Moreover my reaction catalyst has been found to be useful for the preparation of any of the unsymmetrical alkyl hydrazines. The following examples are provided to more clearly illustrate the invention:

Example I.—Preparation of palladium charcoal catalyst

1 part of 10% palladium charcoal and 10 parts of water was stirred in a hydrogen atmosphere until the catalyst was activated, that is, until no additional hydrogen was absolved.

Example II.—Preparation of dimethyl hydrazine

5 parts of nitroso dimethyl amine in 90 parts of water were added to the catalyst as prepared above and subjected to hydrogen atmosphere with rapid stirring. After a quantity equivalent to 2 moles of hydrogen had been absorbed the reaction was stopped, the catalyst filtered, and the water solution neutralized with hydrochloric acid. After evaporation of the water a yield equivalent to 81% of the theoretical of dimethyl hydrazine hydrochloride was isolated.

Example III.—Preparation of ethyl methyl hydrazine

5 parts of nitroso ethyl methyl amine in 90 parts of water were added to the catalyst as prepared in Example I and subjected to hydrogen atmosphere with rapid stirring. After an amount of hydrogen gas equivalent to 2 moles of hydrogen had been absorbed the reaction was stopped. The catalyst was filtered off and the water solution neutralized with hydrochloric acid. The water was distilled off and a theoretical yield of 79.2% ethyl methyl hydrazine hydrochloride was isolated.

In the same fashion simply by selecting the appropriate alkyl substituted nitroso amine and reducing it in accordance with the examples set forth above, any of the alkyl substituted hydrazines may be prepared.

The concentration of the catalyst has not been found to be critical, however, we have found that optimum results are obtained when the palladium-charcoal catalyst is present in an amount below 2.0% by weight. No appreciable differences where observed when amounts in excess of 2.0% were used, however, when amounts below 0.2% were used, a slight decrease in the rate of reaction was observed.

Any of the aforementioned catalysts may be used successfully in the performance of my invention. The palladium metal, itself, being the catalytic substance, is substantially unaffected by the particular carrier or means of introduction employed.

My process, as is evident, lends itself equally well to continuous or batch processes, hence is well adapted to commercial production of unsymmetrical hydrazine compounds.

I claim:

1. The method of preparing unsymmetrical lower alkyl hydrazines which comprises reducing a nitroso amine having the general formula:

$$\overset{R}{\underset{R'}{>}}N{-}NO$$

wherein R and R′ are lower alkyl radicals, with hydrogen in aqueous solution in the presence of a hydrogen activated palladium metal catalyst.

2. The method of claim **1** wherein the hydrogen activated palladium catalyst used is a catalyst selected from the group consisting of palladium on charcoal, palladium on calcium carbonate, palladium on barium sulfate, colloidal palladium metal, and finely divided palladium metal a catalyst carrier.

3. The method of claim **1** wherein the catalyst used is hydrogen activated palladium on charcoal.

4. The method of claim **1** wherein the hydrogen activated palladium catalyst is present in an amount of from about 0.2% to 2.0% by weight.

5. The method of preparing unsymmetrical dimethyl

3,000,968
METHOD OF PREPARING NITRO COMPOUNDS
Karl Klager, Monrovia, Calif., assignor to Aerojet-General Corporation, Azusa, Calif., a corporation of Ohio
No Drawing. Filed Mar. 5, 1956, Ser. No. 570,204
13 Claims. (Cl. 260—644)

This invention relates to new high explosive compositions of matter and to a method of preparing them. This invention also relates to a new process for introducing nitroalkyl groups into organic compounds.

This application is a continuation-in-part of my copending application Serial No. 337,212, filed February 16, 1952, now abandoned.

The new compositions of matter of this invention are trinitroalkane compositions, having the general formula:

$$R-\underset{NO_2}{\overset{NO_2}{C}}-CH_2-\underset{NO_2}{CH}-R''$$

wherein R and R'' are hydrogen or lower alkyl radicals.

The new process of this invention is useful in preparing the compounds having the general formula:

$$R-\underset{R'}{\overset{NO_2}{C}}-CH_2-\underset{NO_2}{CH}-R''$$

wherein R is a nitro, halogen, hydrogen or lower alkyl radical and R' and R'' are hydrogen or lower alkyl radicals.

This process can be used to prepare the new compounds of this invention, as well as a variety of other known compounds having different utilities and properties. The conventional method for introducing nitroalkyl groups into organic compounds has been to react the compound with a nitro-olefin. This process generally leads to relatively poor yields due to the tendency of nitro-olefins to polymerize, thereby preventing the occurrence of the reaction and at the same time rendering separation of the desired product, if any, difficult.

The new process of this invention permits the introduction of nitroalkyl groups into organic compounds without employing any nitro-olefin. The reaction proceeds smoothly and produces the desired product in high yield. The new process of this invention proceeds according to the general reaction scheme set forth below:

$$R-\underset{R'}{\overset{NO_2}{C}}-H+MOH\longrightarrow R-\underset{R'}{\overset{NO_2}{C}}-M+H_2O \qquad (1)$$

$$R-\underset{R'}{\overset{NO_2}{C}}-M+X-\overset{O}{\overset{\|}{C}}-O-CH_2-\underset{NO_2}{CH}-R''\longrightarrow$$
$$R-\underset{R'}{\overset{NO_2}{C}}-CH_2-\underset{NO_2}{CH}-R''+X-\overset{O}{\overset{\|}{C}}-OM \qquad (2)$$

wherein R is a nitro, halogen, hydrogen or lower alkyl radical, R' is a hydrogen or lower alkyl radical, R'' is a hydrogen or lower alkyl radical, X is a lower alkyl, phenyl or lower arylalkyl radical, such as benzyl, and M is a monovalent radical of an alkali or alkaline earth metal. The reaction is preferably conducted at a temperature of about 40° C., however, the reaction temperature can be varied over an extremely wide range of temperatures if desired. Methanol is the preferred solvent, however, any inert organic solvent can be used if desired. While any of the alkali or alkaline earth metal hydroxides can be used in the preparation of the aci-salt, it is preferred to use sodium hydroxide for reasons of economy, and because

2

the sodium aci-salts are generally more soluble than other alkali and alkaline earth metal salts. The lithium salts are about as soluble as the sodium salts, however, the relatively high cost of lithium hydroxide makes it more economical to use sodium hydroxide in the practice of this invention.

X, the acid portion of the ester reactant in the general reaction scheme set forth above, can be any organic radical including phenyl, alkyl, benzyl, etc., since the acid portion of the ester does not enter into the reaction. For reasons of economy, X is preferably a methyl radical.

The alkali or alkaline earth metal aci-salt can be prepared in situ in the presence of the ester reactant or can be prepared separately in advance.

The following examples are presented to more clearly define my invention. It should be understood, however, that the examples are presented purely for purposes of illustration and that the invention is to be limited only by the scope of the appended claims.

EXAMPLE I

Preparation of 1,3,3-trinitrobutane

A solution of 120 g. of 2,2-dinitroethane was placed in 1000 ml. of 4% aqueous sodium hydroxide and the mixture heated to 40° C. With constant stirring, 133 g. of nitroethyl acetate in 150 ml. of methanol was added slowly over a period of 30 minutes. After additional stirring for two hours at 40–45° C., two phases were observed to form. The mixture was then diluted with 2000 ml. methylene chloride and twice washed with water. The solvent was then removed by evaporation and the residue distilled at a pressure of 10 microns. The product boiled between 102 and 102.5° C. The yield of 1,3,3-trinitrobutane was 87 g.

The calculated composition for the empirical formula is: $C_4H_3N_3O_6$: Percent C, 24.88; percent H, 3.65; percent N, 21.76.

The ultimate analysis of the above compound showed: percent C, 25.27; percent H, 3.74; percent N, 21.65.

The index of refraction at 25° was 1.4760.

EXAMPLE II

Preparation of 1,3-dinitro-3-chlorobutane

This compound was prepared by placing in a three-necked flask, having a stirrer, dropping funnel and a reflux condenser, 750 ml. of water containing 44 g. of sodium hydroxide and cooling the solution to between 10 and 15° C. 110 g. of 1-chloro-1-nitroethane was added slowly to form the sodium salt thereof. The mixture was heated to between 30–35° C. and to the solution was added slowly 133 g. of nitroethyl acetate. The temperature was raised to 40–45° C. and was maintained at that point for one hour. At this stage, two phases were seen to form.

2500 ml. of methylene chloride was added to the mixture and the mixture washed twice with water. After drying the methylene chloride solution over sodium sulfate, the solvent was evaporated and the residue distilled at one micron at a temperature of between 80 and 90° C. in an air bath. 60 g. of 1,3-dinitro-3-chlorobutane was produced. The index of refraction for this compound n_D^{25} was 1.4723.

EXAMPLE III

Preparation of 1,3-dinitro-3-methylbutane

44 g. of sodium hydroxide was dissolved in 750 ml. of water. To this solution, 89 g. of 2-nitropropane was added after cooling the solution to 10 to 15° C. When the aci-sodium salt formation was complete, a solution of 13.3 of nitroethyl acetate and 250 ml. of methanol was added slowly at a temperature between 40–45° C.

SOLID PROPELLANT COMPOSITIONS CONTAINING POLYURETHANE RESINS
Karl Klager, Richard D. Geckler, and Richard L. Parrette, Sacramento, Calif., assignors to Aerojet-General Corporation, Azusa, Calif., a corporation of Ohio
No Drawing. Filed July 20, 1959, Ser. No. 829,182
17 Claims. (Cl. 149—19)

This invention relates to novel solid propellant compositions and in particular to novel propellant compositions comprising a polyurethane binder with a finely divided oxidizing agent dispersed therein.

Solid propellant compositions are ordinarily composed of a resin fuel and an oxidizing material, the oxidizing material being intimately dispersed in the fuel. The ignition and burning properties of such propellant compositions, as well as their physical properties, are dependent to a large extent upon the particular resins employed as fuels.

In the novel propellant compositions of this invention polyurethanes are used as the resin fuel component to produce propellants of unexpectedly superior physical properties and performance characteristics. Our novel polyurethane propellants have substantially no internal strains due to the fact that there is little shrinkage and low heat of reaction during polymerization of the polyurethane fuel component. This lack of internal strain is important in that it assures substantial freedom of the propellant grain from cracking during burning. As those skilled in the art realize, propellant cracking is highly undesirable and dangerous and can result in erratic burning or even explosion of the propellant grain.

In addition to their freedom from cracking, the polyurethane propellants of this invention are superior in other ways. For example, they are possessed of sufficiently tenacious adhesive properties to enable them to be bonded directly to the rocket chamber lining, thus permitting optimum utilization of the available space in the rocket motor and simplifying manufacturing techniques. The novel polyurethane propellants of our invention are also possessed of many other desirable physical properties for example: rubbery mechanical qualities, low brittle point, excellent resilience and superior aging properties.

Our novel solid propellants can be used as the primary propulsion source in rocket-propelled vehicles or as a propellant for artillery missiles. When used as the primary propulsion source for rocket vehicles, they can be conveniently ignited by a conventional igniter, as for example, the igniter disclosed in assignee's copending application Serial No. 306,030, filed August 23, 1952 now, Patent No. 3,000,312. The propellant is preferably cast directly in the rocket chamber in which it is to be fired and restricted on one or both ends in the conventional manner with a relatively slow burning inert resin, such as a polyurethane or a polyester resin. The restriction is preferably accomplished by applying a relatively thin coating of the inert resin to the inner surfaces of the rocket chamber lining prior to casting the propellant therein. Rocket chambers such as those in which our novel solid propellants are employed are ordinarily of the conventional type having one end open and leading into a venturi rocket nozzle. Upon ignition, large quantities of gases are produced and exhausted through the nozzle creating propulsive force.

The polyurethane binders of our invention are prepared by reacting a compound having two active hydrogen groups capable of reacting with an isocyanate with an organic compound having as the sole reacting groups, two isocyanate or isothiocyanate groups. The compound having the active hydrogen groups is preferably an organic compound having as the sole reacting groups, hydroxyl or thiol groups.

2

It will be appreciated that in any given batch of propellant the individual polyurethane molecules may vary in length from several to tens of thousands of repeating units, hence molecular weight figures on polyurethanes represent statistical averages. The exact nature of the terminal groupings is not known and will vary depending upon whether plasticizers, polymerization catalysts, etc., are present. Moreover a given molecule may even form a ring and thus leave no dangling radicals.

It is evident from the above that a wide variety of polyurethane binders for the propellants of this invention can be prepared simply by varying the particular isocyanate and hydroxy starting materials.

The isocyanate starting materials for our polyurethane binders are diisocyanate compounds which can be saturated or unsaturated; aliphatic or aromatic; open or closed chain; and, if the latter, monocyclic or polycyclic; and substituted or not by groups substantially unreactive with isocyanate or hydroxyl groups, such as, for example, ketone, halogen, ester, sulfide or ether groups. The following diisocyanate compounds are particularly suitable as reactant for the preparation of binders for our novel polyurethane propellants.

(*a*) Alkane diisocyanates such as:
  Ethylene diisocyanate;
  Trimethylene diisocyanate;
  Propylene-1,2-diisocyanate;
  Tetramethylene diisocyanate;
  Butylene-1,3-diisocyanate;
  Decamethylene diisocyanate;
  Octadecamethylene diisocyanate;
  etc.
(*b*) Alkene diisocyanates such as:
  1-propylene-1,2-diisocyanate;
  2-propylene-1,2-diisocyanate;
  1-butylene-1,2-diisocyanate;
  3-butylene-1,2-diisocyanate;
  1-butylene-1,3-diisocyanate;
  1-butylene-2,3-diisocyanate;
  etc.
(*c*) Alkylidene diisocyanates such as:
  Ethylidene diisocyanate;
  Propylidene-1,1-diisocyanate;
  Propylidene-2,2-diisocyanate;
  etc.
(*d*) Cycloalkylene diisocyanates such as:
  Cyclopentylene-1,3-diisocyanate;
  Cyclohexylene-1,2-diisocyanate;
  Cyclohexylene-1,3-diisocyanate;
  Cyclohexylene-1,4-diisocyanate;
  etc.
(*e*) Cycloalkylidene diisocyanates such as:
  Cyclopentylidene diisocyanates;
  Cyclohexylidene diisocyanate;
  etc.
(*f*) Aromatic diisocyanates such as:
  m-Phenylene diisocyanate;
  o-Phenylene diisocyanate;
  p-Phenylene diisocyanate;
  1-methyl-2,4-phenylene diisocyanate;
  Naphthylene-1,4-diisocyanate;
  Diphenylene-4,4'-diisocyanate;
  2,4-tolylene diisocyanate;
  2,6-tolylene diisocyanate;
  4,4'-diphenylmethane diisocyanate;
  1,5-naphthalene diisocyanate;
  Methylene-bis-(4-phenylisocyanate);
  2,2-propylene-bis-(4-phenylisocyanate);
  Xylene-1,4-diisocyanate;

SOLID PROPELLANT COMPOSITIONS CONTAINING POLYURETHANE RESINS OF LOW CURE TEMPERATURE

Karl Klager, Richard D. Geckler, and Richard L. Parrette, Sacramento, Calif., assignors to Aerojet-General Corporation, Azusa, Calif., a corporation of Ohio
No Drawing. Filed July 20, 1959, Ser. No. 829,180
32 Claims. (Cl. 149—19)

This invention relates to novel solid propellant compositions and in particular to novel propellant compositions comprising a cross-linked polyurethane binder with a finely divided oxidizing agent dispersed therein.

Solid propellant compositions are ordinarily composed of a resin fuel and an oxidizing material, the oxidizing material being intimately dispersed in the fuel. The ignition and burning properties of such propellant compositions, as well as their physical properties, are dependent to a large extent upon the particular resins employed as fuels.

In the novel propellant compositions of this invention, cross-linked polyurethanes are used as the resin fuel component to produce propellants of unexpectedly superior physical properties and performance characteristics.

The novel polyurethane propellants of our invention can be cured at low cure temperatures and in addition exhibit no measurable heat of reaction. As a result of these unique properties they are not subject to shrinkage and have no internal strains. Composite propellant systems heretofore used have all been severely restricted in their use because of high heats of reaction and the need for high cure temperatures which produce shrinkage and internal stresses. These faults have heretofore imposed severe restrictions upon the size of solid propellant motors because of their tendency toward cracking as a result of internal strains. We have produced a propellant which constitutes a major breakthrough in rocket technology in that solid propellant motors are no longer subject to size limitations and can be manufactured in sizes as large as desired using the novel propellant compositions of our invention.

In addition to their freedom from cracking, the polyurethane propellants of this invention are superior in other ways. For example, they are possessed of sufficiently tenacious adhesive properties to enable them to be bonded directly to the rocket chamber lining, thus permitting optimum utilization of the available space in the rocket motor and simplifying manufacturing techniques. The novel polyurethane propellants of our invention are also possessed of many other desirable physical properties, for example: rubbery mechanical qualities, low brittle point, excellent resilience, and superior aging properties.

Our novel solid propellants can be used as the primary propulsion source in rocket-propelled vehicles or as a propellant for artillery missiles. When used as the primary propulsion source for rocket vehicles, they can be conveniently ignited by a conventional igniter, as for example, the igniter disclosed in assignee's copending patent application Serial No. 306,030, filed August 23, 1952. The propellant is preferably cast directly in the rocket chamber in which it is to be fired and restricted on one or both ends in the conventional manner with a relatively slow burning inert resin, such as a polyurethane or a polyester resin. The restriction is preferably accomplished by applying a relatively thin coating of the inert resin to the inner surfaces of the rocket chamber lining prior to casting the propellant therein. Rocket chambers such as those in which our novel solid propellants are employed are ordinarily of the conventional type having one end open and leading into a venturi rocket nozzle. Upon ignition, large quantities of gases are produced

and exhausted through the nozzle creating propulsive force.

The polyurethane binders of our invention are prepared by reacting a compound having two or more active hydrogen groups capable of polymerized with an isocyanate, with an organic compound having as the sole reacting groups, two or more isocyanate or isothiocyanate groups. The compound having the active hydrogen groups is preferably an organic compound having as its sole reacting groups, hydroxyl or thiol groups.

It will be apparent that, where there are more than two active hydrogen, isocyanate, or isothiocyanate groups present on any of the polyurethane reactions, the resulting molecular structure of the polyurethane binder will be at least to a certain extent of a cross-linked rather than a linear nature. The cross-linking is accomplished when all three functional groups of a sufficient number of the trifunctional molecules undergo the urethane reaction with other groups present in the mixture, thus resulting in a product having a "three-dimensional" molecular structure rather than mere aggregates of linear chains as is the case when bifunctional reactants are employed.

Where bifunctional reactants, such as dihydroxy compounds and diisocyanates, are employed to produce the polyurethane binders for our novel propellants, it is necessary to also employ a "cross-linking" agent to assure a product having the cross-linked structure essential to this invention. Cross-linking agents can also be used with polyurethane reactants having more than two functional groups, such as triols and/or triisocyanates, within the scope of this invention. Compounds suitable as cross-linking agents for our polyurethane binders are those organic compounds having as the sole reacting groups three or more groups polymerizable with hydroxy or isocyanate groups.

It will be appreciated that in any given batch of propellant the individual polyurethane molecules may vary in number of repeating units from several to tens of thousands of these units, hence molecular weight figures on polyurethanes represent statistical averages. The exact nature of terminal groupings is not known and will vary depending upon whether plasticizers, polymerization catalysts, etc., are present. Moreover, a given molecule may even form a ring and thus leave no dangling radicals.

It is evident from the above that a wide variety of polyurethane binders for the propellants of this invention can be prepared by varying the particular isocyanate and hydroxy starting materials.

The isocyanate starting materials for our polyurethane binders are preferably diisocyanates but not necessarily so since, as explained above, other polyisocyanates (such as triisocyanates) or polyisothiocyanates may be employed within the scope of the invention if desired.

Our preferred diisocyanate compounds can be saturated or unsaturated; aliphatic or aromatic; open or closed chain, and, if the latter, monocyclic or polycyclic; and substituted or not by groups substantially unreactive with isocyanate or hydroxyl groups such as, for example, ketone, halogen, ester, sulfide, or ether groups. The following diisocyanate compounds are particularly suitable as reactants for the preparation of binders for our novel polyurethane propellants:

(a) Alkane diisocyanates, such as:

Ethylene diisocyanate;
Trimethylene diisocyanate;
Propylene-1,2-diisocyanate;
Tetramethylene diisocyanate;
Butylene-1,3-diisocyanate;
Decamethylene diisocyanate;
Octodecamethylene diisocyanate;
etc.
